THE COLLEGE OF SURGEONS' license, or L.R.C.S.I., is universally sought for by those students who do not resort to a University. Its course of study has hitherto extended over three, but will henceforth cover four years, and it holds the only extra-university preliminary examination, save that of the Apothecaries' Hall. It grants the higher qualification of Fellow or F.R.C.S.I., to those who are specially qualified and specially examined for that diploma, and it also confers a midwifery diploma on examination by a special Court of Examiners.

THE COLLEGE OF PHYSICIANS grants its license, L.K.Q.C.P.—the usual medical qualification of the Irish student—which is almost always taken by the young surgeon immediately after his passing at the College of Surgeons, and for it the same curriculum of study is sufficient. The College has recently established a higher qualification of "Member," for which there is a special examination, and there is also the still higher grade of Fellow of the College, to which admission is by ballot without examination or curriculum.

The cost of obtaining the L.R.C.S.I. with the L.K.Q.C.P.I., and the license in midwifery, is nearly as possible as follows:—

Lectures, &c.	£85	0	0
Hospital	36	0	0
Diploma fees L.R.C.S.	26	0	0
Diploma fees L.K.Q.C.P.	15	15	0
Diploma fees Lic. Mid.	3	3	0
	<hr/>		
	£145	18	0

The lecture fees may be reduced to £67 by making a cash composition for them; but, as a certificate of study in vaccination is now required, a course of clinical instruction in ophthalmology, and a course of attendance at a midwifery hospital is required for the midwifery diploma, the total expense of the Dublin double diploma may be set down at £155.

The regulations of these bodies will be found at page 264.

THE APOTHECARIES' COMPANY grants a registrable license (L.A.H.), which is accepted by the Local Government Board as a medical qualification, and which, in addition, entitles the holder to keep open shop and sell drugs in Ireland. It only costs 10s., and it is taken in lieu of the License of the College of Physicians by a few students to whom the money cost of their qualification is vitally important, or who intend to open an establishment in some of the provincial towns for the dispensing of medicines. Since the establishment of the Irish Pharmaceutical Society, which is empowered to grant pharmacy licenses, the demand for the L.A.H. has been nominal. The cost of the L.A.H., with the necessary curriculum of study, is about £59; that of the L.R.C.S.I., combined with the L.A.H., and a License in Midwifery, is about £130.

QUEEN'S UNIVERSITY IN IRELAND.—Since the issue of our last Students' Number this University has ceased to exist, being superseded by the Royal Irish University, which holds its first matriculation examination on the 6th of December next. All medical graduates are, *ipso facto*, entitled to become medical graduates of the Royal Irish University. The existing students in medicine of the Queen's University will also, on obtaining their degree from the Royal Irish University, be entitled to receive the

title of M.D., which, under other circumstances, will be granted only to full graduates in Arts.

THE ROYAL IRISH UNIVERSITY.—This institution was incorporated and organised within the past year, and it holds its first matriculation examination on the 6th of December next. The degrees of the University will be granted on one year's Arts, *i.e.*, the matriculation examination of the University (none other will suffice) and a "first University examination" at the termination of the first year. The cost of the M.B. and M.Ch. of the University with all the necessary curriculum will be about £69. The examinations will be conducted not only in Dublin but at certain local centres, but no dates have yet been fixed. The regulations which appear at 263 are those adopted by the Senate, but they are subject to modification, especially in regard to the amounts of the prizes to be awarded.

The regulations of the "Hall" will be found on page 266.

NOTE.—Our advertising columns, of which an index will be found at the end of the editorial matter, will supply further information, with the names of staff, &c., attached to the foregoing schools.

PRELIMINARY EXAMINATION AND REGISTRATION IN IRELAND.

We call the special attention of students who intend taking the L.R.C.S.I. to the fact that—for the future—they must pass their preliminary examination, and register themselves at the Branch Medical Council, 35 Dawson Street, before they enter on medical study; otherwise, their lecture and hospital certificates for courses commenced before they have done so will not count.

OFFICIAL REGULATIONS OF LICENSING BODIES IN IRELAND. UNIVERSITY OF DUBLIN.

(For Names of Professors and Examiners see Advertisement in our pages).

REGULATIONS OF THE SCHOOL OF PHYSIC.

Matriculation.—Every student must be matriculated by the Senior Lecturer, for which a fee of 5s. is payable; but he need not attend any of the Arts courses unless he desire to obtain a licence or degree in medicine or surgery. No student can matriculate unless he has passed the Entrance Examination in Trinity College, in the Royal College of Surgeons of Ireland, or some other examination recognised by the General Medical Council. No student can be admitted for the Winter Courses after the 25th November.

QUALIFICATIONS FOR DEGREES AND LICENCES.

Bachelor in Medicine.—Candidates must be graduates in Arts, and may obtain the degrees at the same commencement as the B.A., or at any subsequent one. The medical education of a Bachelor in Medicine is of four years' duration, and comprises the following lectures:—

Winter Courses.—Anatomy; physiology; practical anatomy; surgery; chemistry; practice of medicine; midwifery; heat, electricity, and magnetism.

Summer Courses.—Botany; pharmacology and therapeutics; practical histology; medical jurisprudence; comparative anatomy. Hospital attendance on a medico-chirurgical hospital during three courses of nine months each, with clinical lectures, including actual attendance on fever; six months' practical midwifery; six months' dissections; and three months' laboratory instruction in chemistry are required. The Courses may be attended at any recognised medical school. The fee for the *Liceat ad Examinandum* is £5. The fee for the degree of M.B. is £11.

Doctor in Medicine.—A Doctor in Medicine must be M.R., or qualified to take that degree for three years. He must also read a thesis before the Regius Professor of Physic. Total fee for this degree, £13.

Bachelor in Surgery must be B.A., have spent four years in the study of surgery and anatomy, and passed the M.B. examination. The curriculum comprises the following, in addition to the course for the M.B.:—

Theoretical and operative surgery ..	One course.
Dissection	Two courses.
Ophthalmic surgery	One course.

Candidates are required to perform operations on the dead subject. Fee for the *Licent ad Examinandum*, £5. Fee for the degree of Bachelor in Surgery, £5.

Master in Surgery must be a B.Ch. of three years' standing, and must read a thesis. Fee for the degree of Master in Surgery, £11.

Master in Obstetric Science.—A Master in Obstetric Science must have passed the M.B. and B.Ch. Examinations, and produce certificates of having completed the following curriculum:—1. One Winter course in midwifery. 2. Six months' practice in a recognised lying-in hospital or maternity. 3. A Summer course in obstetric medicine and surgery. 4. Two months' practice in the Cow-pock Institution. Graduates of medicine of M.D. standing may present themselves for examination without complying with Regulations 3 and 4. Fee for the degree of M.A.O., £5.

UNIVERSITY LICENCES.

Candidates for the licence in medicine or surgery must be matriculated in medicine, and must have completed *two years in Arts*.

Licentiate in Medicine.—The course and examination are the same as for the M.B. An L.M. on proceeding to the degree of B.A. may become an M.B. on paying the fees without further examination. Fee for the *Licent ad Examinandum*, £5. Fee for the licence in medicine, £5.

Licentiate in Surgery.—The course and examination necessary for the Licence in surgery is the same as for the degree of Bachelor in surgery. Fee for the *Licent ad Examinandum*, £5. For the licence in surgery, £5.

MEDICAL SCHOLARSHIPS.

Two Medical Scholarships are given annually, value £20 per annum each, tenable for two years, the examinations for which are held each year in June, in the following subjects:—Anatomy and institutes of medicine, chemistry, materia medica, botany, experimental physics, and comparative anatomy.

The board of Trinity College have recently passed orders—1. That three-fourths of the lectures must be attended. 2. That a daily roll be called by each Professor.

Students entering for demonstrations and dissections are required to pay £8 8s. before November 25; dissections only, £5 5s.; demonstrations only, £3 3s.; fourth year's dissections, £2 2s.

ROYAL UNIVERSITY OF IRELAND.

The University will confer the following medical degrees:—

Bachelor of Medicine, M.B.; Doctor of Medicine, M.D. Master of Surgery, M.Ch.; in Obstetrics, a special diploma; in Sanitary Science, a special diploma.

All degrees are open to persons of either sex. The examinations for women shall be held apart from those for men, but upon the same days.

The University examinations shall commence on the third Tuesday in September.

Candidates for any degree must have passed the Matriculation Examination of the University. *Students from other Universities and Colleges are included.*

This Examination shall be conducted not only in Dublin, but at certain local centres selected by the Senate.

Every candidate for Matriculation must send in to the secretaries his name and address, and pay a fee of 10s.

The following are subjects:—

I.—Latin.

II.—Any one of the following languages:—Greek, French, German, Italian, Spanish, Celtic, Sanskrit, Hebrew, or Arabic.

III.—English language.

IV.—Elementary Mathematics.

V.—Experimental Physics.

THE UNIVERSITY COURSE.

Candidates for all degrees must pass the First University Examination,

The courses for the degrees of M.B. and M.Ch., and the Diplomas in Obstetrics and in Sanitary Science, shall extend over at least four years. Candidates will be required, in addition to the First University Examination, to pass the following Examinations:—

- First Professional Examination.
- Second Professional Examination.
- The Degree Examination.

They may, however, pass the First University Examination at the same time as the First Professional Examination.

Candidates for the M.D. may present themselves after the lapse of two Academic years from the date of obtaining the degree of M.B. Those candidates who are Students in Medicine in the Queen's University at the date of its dissolution shall be entitled, if they so desire, to obtain the degree of M.D., instead of the degree of M.B., upon passing the Degree Examination.

FIRST UNIVERSITY EXAMINATION.

Students will be admitted to this Examination after one Academic year from Matriculation.—Fee, £1.

Candidates at this Examination will be required to answer in the following subjects:—

I.—Latin.

II.—Any one of the following languages, viz.:—Greek, French, German, Italian, Spanish, Celtic, Sanskrit, Hebrew, or Arabic.

III.—English language and Literature.

IV.—Mathematics.

V.—Experimental Physics.

FACULTY OF MEDICINE.

The first period of Medical Study shall comprise—*a.* Chemistry, six months; *b.* Practical Chemistry, three months in a chemical laboratory; *c.* Botany, with Herborization for practical study, and Zoology; *d.* Anatomy and Physiology; *e.* Practical Anatomy; *f.* Materia Medica. The second period—*a.* Anatomy and Physiology, including Histology; *b.* Practical Anatomy; *c.* Theory and Practice of Surgery; *d.* Midwifery and Diseases of Women, six months; *e.* Theory and Practice of Medicine; *f.* Medical Jurisprudence.

Candidates are further required to have attended during the first period—Medico-Chirurgical, a winter of six months; and during the second period—Practical Midwifery, Midwifery Hospital, six months, or six months at a Midwifery Dispensary where similar Clinical instruction is given (the certificate must state that the candidate has attended at twenty labours); Medico-Chirurgical Hospital, eighteen months, including either three winters, or two winters and two summers.

Candidates must also before the Degree Examination produce certificates—(1) of personal attendance on fever cases; (2) of having compounded under an apothecary or pharmaceutical chemist for at least three months; (3) of instruction in vaccination; (4) of having attended a course of lectures (not less than 25) and Clinical instruction on Mental Diseases.

The Senate further recommend that students should avail themselves of opportunities of attendance on lectures on diseases of the Eye, Ear, and other special departments of medicine and surgery.

Candidates for honours must pass the above Examinations before competing for honours, and their answering at the Pass will be taken into account for honours.

FIRST UNIVERSITY EXAMINATION IN MEDICINE.

The fee for this Examination is £1.

The subjects—*a.* Zoology; *b.* Botany; *c.* A Modern Language.

Candidates who have passed in a Modern Language at the ordinary First University Examination are exempt from presenting this subject.

SECOND UNIVERSITY EXAMINATION IN MEDICINE.

The Second University Examination in Medicine comprises the following subjects:—Anatomy, Physiology, Materia Medica, and Chemistry.

Before being admitted to this Examination, each student must produce satisfactory evidence of having completed the course recommended for study during the first period. Fee, £1.

EXAMINATION FOR THE M.B. DEGREE.

Fee, £3. Each candidate must produce certificates of having completed all the prescribed courses.

The Examination comprises the subjects recommended for study during the second period, and includes Examinations in Clinical Medicine and Clinical Surgery.

EXAMINATION FOR THE M.O.E. DEGREE.

Conferred only on graduates in Medicine of the University. Fee, £5.

The Examination comprises Theory and Practice of Surgery, including Operative and Clinical Surgery.

EXAMINATION FOR THE DIPLOMA IN OBSTETRICS.

Conferred only on graduates in Medicine of the University. Fee, £2.

The Examination comprises Theory and Practice of Midwifery, and the use of Obstetrical instruments and appliances.

EXAMINATION FOR THE DIPLOMA IN SANITARY SCIENCE.

Conferred only on graduates in Medicine of the University. Fee, £2.

The Examination shall embrace the following subjects:—Climate, Chemistry, Geology, Physics; Vital Statistics; Hygiene, Sanitary Law.

The Examination in Chemistry shall include a practical part on the chemical and microscopical examination of air, water, food, poisonous substances used in manufacture, &c.

The Examination in Physics shall embrace the reading of plans, sections, scales, &c., in connection with buildings, sanitary constructions, &c.

EXAMINATION FOR THE M.D. DEGREE.

Fee, £5.

The degree of Doctor may be conferred on any candidate who has obtained the M.B., and has produced a certificate of having been for the last two years engaged in hospital or private medical or surgical practice, or in the military or naval medical service, provided that the candidate shall submit to the medical examiners a thesis composed by himself, and approved by them. No thesis will be approved which does not contain some original or personal observations in practical Medicine, Surgery, Midwifery, or in some of the Sciences embraced in the Curriculum, or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted.

Candidates settled for a period of two years in the colonies or foreign countries may, on satisfying the Senate to that effect, and complying with the conditions above described, have the degree conferred on them in absence.

ROYAL COLLEGE OF SURGEONS OF IRELAND.

SINCE our last Students' Number the Council of the College and the College itself have decreed an entirely new system of education and examination requisite for the College licence, and compulsory upon all students who commence their studies after this date. As especially it is our business to provide information for the student who is about to commence his first year of study, we substitute the new scheme for the old regulations (which may be found in the Irish Medical Directory, or last year's Students' Number); but it is to be remembered that students who have already commenced medical study may present themselves either under the old or new system.

THE NEW SCHEME OF THE EDUCATION AND EXAMINATION FOR THE L.R.C.S.I.

Every candidate shall produce evidence:—1. Of having, before entering on medical studies, passed the preliminary examination of the College, or an equivalent examination in general education, recognised by the General Medical Council; and 2. Of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised by the College, if the date of commencement of the course to which the certificate refers is more than fifteen days prior to such registration.*

* The several Branch Councils have power to admit special exceptions to the regulation as to registration for reasons which shall appear to them satisfactory.

The College recognises as the commencement of professional study:—

1. Attendance on the practice of a hospital, or other public institution recognised by the College for that purpose; or,
2. Instruction as pupil of a legally qualified surgeon, holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council; or,
3. Attendance on lectures on anatomy, physiology, or chemistry, by lecturers recognised by this College.

The letters testimonial of the College shall not be granted to any candidate at an earlier period than forty-five months subsequent to his registration as a medical student; or to any one who has not attained the age of twenty-one years.

Registered Pupils of the College.—Any student may be registered as a pupil in the College books on payment of a registration fee of £5 5s., for which credit will be given subsequently in his examination fee. No student can be admitted as a candidate to examination until he shall have been so enrolled, and passed the preliminary examination.

Privileges of Registered Pupils.—Registered pupils are admitted to the preliminary examination, but are not entitled to re-examination without further fee. They are permitted to study in the museum, to read in the library, and attend the lectures of comparative anatomy, and to obtain a certificate for such attendance without fee.

Examinations.—Every candidate must pass a preliminary examination and four professional examinations. Candidates who possess a diploma or degree in either medicine or surgery, or who have passed a sufficient examination in these subjects, may be exempted from compliance with this rule.

Candidates must return their names, fees, and certificates one week before examination.

Preliminary Examination.—All students must pass their preliminary examination before entering upon their professional studies.

The preliminary examinations are held quarterly, viz.:—on the 3rd Wednesday in Jan., April, July, and Oct., in the following subjects, with permission to the student to select French, German, or Greek:—1. English, including grammar and composition; 2. Arithmetic, including vulgar and decimal fraction; 3. Algebra, including simple equations; 4. Geometry, first two books of Euclid; 5. Latin—the first and Second Books of the *Æneid* of Virgil, or the *Jugurthine War* of Sallust, or the Third Book of Livy; 6. Physic, as may be found in Ganot's Popular Natural Philosophy. The examination in physics may be passed either at the preliminary or the first professional examination.

Alternative subjects—One to be selected by the student:—1. Greek—the Gospel of St. John, or the First Book of Xenophon's *Anabasis*, or the Dialogue of Lucian, entitled "Menippus or the Necromancy;" 2. French—Fénélon's "Télémaque;" 3. German—Schiller's "Wilhelm Tell."

Fees.—Registered pupils of the College free. Non-registered pupils, £1 1s. Rejected candidates, whether registered pupils or not, shall pay a further fee of £1 1s. for each re-examination.

Professional Examinations.—The 1st, 2nd, and 3rd professional examinations shall be held in the July and October of each year; should the student fail to pass in July he may present himself at the examination held in October.

The examination of each year must be passed before a new session can be entered on.

First Professional Examination.—Candidates must, before admission to the first preliminary examination, produce evidence of having passed the preliminary examination, and of having been registered as students, and of having been engaged in study for at least nine months after registration.

Candidates are recommended to attend a course of lectures on practical anatomy, and one on chemistry before this examination.

The examination shall include the following subjects, viz.:—1. Physic, if not passed at the preliminary examination; 2. The elements of chemistry, as may be found in Roscoe's *Lessons in Elementary Chemistry*, from chap. i. to xiii., inclusive; 3. Botany, as may be found in Oliver's *Lessons in Botany*, Part I., with descriptions of the following plants:—The butter-cup, poppy, pea, strawberry, fox-glove, and dandelion; 4. Anatomy—human osteology; 5. Practical Pharmacy—Elementary.

Fees.—The fee for this examination shall be £5 5s. in addition to the registration fee of £5 5s. Neither of these fees shall be returned in case of rejection, but the candidate on paying an additional sum of £2 2s. shall be admitted to re-examination.

Order of Examination.—The candidates shall be examined in numerical order and the examination shall occupy two days.

First day.—Two hours.

Second Day (Oral).—Three quarters of an hour.

Second Professional Examination.—Candidates must produce evidence of having passed the first professional Examination, also certificates of having subsequently attended:—Hospital, nine months; Winter Courses: Practical anatomy, with demonstrations and dissections; physiology; surgery; chemistry (unless attended in first year); Summer Courses, three months: Practical chemistry, practical physiology, materia medica.

Fees.—The fee for this examination shall be £5 5s. Candidates who are rejected will be admitted to re-examination on paying an additional fee of £2 2s.

Candidates shall be examined in: 1. Anatomy—bones, joints, muscles, and topographical anatomy of the viscera of the chest, abdomen, and pelvis; 2. Histology, and the physiology of the circulatory, respiratory, and digestive systems; 3. Surgery—The signs, terminations, and treatment of inflammation, wounds, hæmorrhage, burns and scalds, ulcers, and bandaging; 4. Chemistry; 5. Materia medica.

Order of Examination.—The candidates shall be examined in numerical order, and the examination shall occupy two days.

First day (Oral), 1 hour.

Second day (dissections and histology)—Each candidate shall make a dissection of a region allotted to him, half-an-hour at least, being allowed for this purpose. He shall then be examined on the anatomy of that part, and may also be examined on regions dissected by other candidates. Preparations of different objects shall be placed under microscopes, and five minutes shall be allowed each candidate to study them before being examined upon them.

Third Professional Examination.—Candidates must produce evidence of having passed the second examination, also certificates of hospital; nine months as an extern pupil, or six months as a resident pupil. Winter courses—Demonstrations and dissections, practical anatomy (unless attended in the first year), surgery, medicine. Summer course, three months—Medical jurisprudence.

Fees.—The fee for this examination shall be £5 5s.; and for re-examination, if rejected, £2 2s.

Candidates shall be examined in—1. Anatomy; 2. Physiology; 3. Surgery, not including operative, clinical, and ophthalmic surgery, which are reserved for the final professional examination.

Order of examination.—The examination shall occupy three days.

First day (printed questions).—Three hours.

Second day (oral).—One hour.

Third day (dissections).—As in second examination.

Fourth, and final professional examination.—The fourth examination shall be held in July and October, and in the following April. Candidates must produce evidence of having passed the third examination, also of having attended hospital nine months as extern pupil, or six months as resident pupil, unless a certificate to that effect has been accepted in the third year. Winter Courses—Dissections and demonstrations; midwifery, a midwifery hospital, or maternity, for six months, and of having been present at thirty labours. (May be attended in the third or fourth year, winter or summer.) Clinical ophthalmology, three months. (May be attended in the third or fourth year, winter or summer.) Operative surgery. Practical instruction in vaccination. (May be attended at any time after registration.)

Fees.—The fee for this examination shall be £5 5s., and £2 2s. for re-examination, if rejected.

Candidates shall be examined in—1. Surgery—clinical, ophthalmic, and operative, with surgical anatomy; 2. Medicine; 3. Midwifery and Diseases of Women; 4. Medical Jurisprudence.

Order of examination.—The examination shall occupy four days.

First day (printed questions).—Two hours.

Second day (oral).—The oral examination shall occupy half-an-hour.

Third day (clinical).—At the clinical examination the candidates must attend at the college on the morning of the examination, and draw from a ballot-box provided for the purpose the name of the hospitals in which they are to

be examined, but no candidate shall be examined in a hospital at which he was in attendance during the session preceding his admission to examination. Each candidate shall be required to make a diagnosis in at least two surgical cases, examining the patients in the presence of the examiners. He shall be questioned upon these cases, and upon others, if necessary. He shall also take notes of another case, to test his accuracy in case-taking. He shall be required to bandage, adjust some surgical appliance, or perform some clinical surgical duty.

Fourth day (operative surgery).—At this examination each candidate shall perform a major and a minor operation, the names of which he shall draw by ballot. He shall be questioned upon these, and on surgical instruments and appliances, and on the relative anatomy of the parts implicated in the operations performed by himself or other candidates.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

THE MEMBERSHIP.

[Under the Provisions of the Supplemental Charter of December 12th, 1878.]

I.—The grade of members is distinct from that of the fellows, and the members as such are not members of the Body Corporate.

II.—Members alone are eligible to the fellowship. They have the use of the reading rooms and library.

III.—Licentiates admitted before December 12th, 1878, are entitled to be admitted members of the College without payment or examination, on giving six weeks' notice, in writing, to the Registrar.

IV.—Every candidate for membership must produce evidence—

1. Of being over 25 years of age.

2. Of being a licentiate of the College for three years at least; or, a licentiate of one year's standing, if also graduate of arts; or, a licentiate of one year's standing, if also a registered practitioner of seven years' standing at the time of his obtaining the license.

3. Of professional conduct and moral character.

4. That he is not engaged in trade; and that he does not directly or indirectly vend medicines or drugs; and that he does not dispense or compound medicines for anyone—even his own private patients—(except in cases of extreme urgency); nor practise medicine or surgery in partnership, by deed or otherwise. (Candidates for the membership by examination must, in addition to the above, show proof as follows) :—

5. Of having attended courses in ophthalmology and histology.

6. Of having been for six months resident physician, or resident pupil, in a recognised hospital; or for some period as clinical clerk in the medical wards, or in medical charge, for at least twelve months, of any public institution for the treatment of the sick.

7. Of having paid the fee of twenty guineas.

V.—Every candidate must pass examination in the following subjects:—Medical Anatomy, Pathology, Histology, Medical Chemistry, Forensic Medicine, Principles of Public Health, including Climatology and Meteorology, Psychology, and Clinical Medicine.

VI.—The examination shall be as follows:—Wednesday, papers of four questions—Medical Anatomy, Medical Chemistry and Forensic Medicine, Pathology, Psychology. An hour and a half allowed to each paper. Thursday—Morning—Clinical examination. Afternoon—The Oral examination.—This examination includes the investigation of morbid specimens, the qualitative analysis of animal products, the detection of poisons, and the use of the microscope, as well as that in classics and modern languages.

LICENSES IN MEDICINE AND MIDWIFERY.

I.—Examinations for the licenses of the College in medicine and midwifery are held in the week following the first Friday in each month, except August and September.

II.—Every candidate for either license must return his name to the registrar, and lodge his certificate, bank receipt of fees, and his schedule at least four days before the first Friday in each month.

THE L.K.Q.C.P.I.

Every candidate is required to produce satisfactory evidence—

1. Of character, from a Fellow of the College, or from two registered practitioners.

2. Of having passed an examination in general education, held by some of the recognised examining bodies.

3. Of having been engaged four years in the study of medicine.

4. Of having attended lectures on the following subjects, at recognised schools—

Practical anatomy, two courses. Physiology, or institutes of Medicine, one course. Chemistry, one course. Practical chemistry, one course. Materia medica, one course. Medical jurisprudence, one course. Practice of medicine and pathology, one course. Surgery, one course. Midwifery, one course.

5. Of twenty-seven months a recognised medico-chirurgical hospital, in which clinical lectures and clinical instruction in medicine are given, the attendance not to be for more than nine months in any one year, and of having not less than three months studied fever in a recognised clinical hospital, containing fever wards, and recorded, from daily personal observation, at least five cases of fever, to the satisfaction of the attending clinical physician, as attested by his signature. (In the case of candidates who commenced their hospital studies between September, 1876, and October, 1879, they will be required to furnish evidence either of having, during nine months of their hospital attendances, studied in an hospital containing fever wards, or of having conformed with the above By-law referring to five fever cases.)

6. Of having attended practical midwifery and diseases of women for six months at a recognised lying-in hospital, or maternity; or, where such hospital attendance cannot have been obtained during any period of the student's course of study, of having been engaged in practical midwifery under the supervision of a registered practitioner holding public appointments; not less than twenty labour cases to be actually attended.

III.—The professional examination is divided into two parts—

First Part—Anatomy, physiology, chemistry, and materia medica.

Second Part—Practice of medicine, clinical medicine, pathology, medical jurisprudence, midwifery, hygiene, and therapeutics.

IV.—Any registered practitioner of *five* years' standing shall be admitted to examination for the license of the College, on producing his certificate of registration, with satisfactory reference, and shall have the privilege of being exempted from the examination by printed questions.

Each candidate shall be examined separately, and shall be required to recognise pathological specimens, and undergo such other practical tests as the examiners shall select.

THE LICENSE IN MIDWIFERY.

Candidates for the license in midwifery, who are not licentiates in medicine, may be admitted to examination on the following qualifications:—

(1) The degree or license from any university or college in the United Kingdom; (2) testimonials as to character; (3) certificates of having attended (a) a course of lectures on midwifery in a school, recognised by the College; (b) practical midwifery and diseases of women, for six months, at a lying-in hospital, or maternity, recognised by the College; or where such hospital attendance cannot have been obtained during any period of the candidate's course of study; of having been engaged in practical midwifery under the supervision of a registered practitioner holding a public medical appointment—the certificate, in either case, to state that not less than twenty labour cases have been actually attended.

Candidates who are already licentiates in medicine of the College, or who have passed the examination for such license, may be admitted to examination for the license in midwifery on lodging their fees, and signifying their wish to the registrar a week, at least, before such examination.

X.—Any registered practitioner of *five* years' standing shall be admitted to examination for the license in midwifery, on producing his certificate of registration, with

satisfactory reference; and he shall have the privilege of being exempted from the examination by printed questions.

FEES FOR LICENSE AND EXAMINATIONS.

XI.—License in medicine, fifteen guineas, which may be divided as follows:—

For examination at the termination of the first period of study, five guineas.

For final examination for the license, ten guineas.

XII.—License in midwifery, three guineas.

XIII.—Fee for examination of the licenses in medicine and midwifery, if obtained within the interval of a month, sixteen guineas—to be lodged in one sum.

XIV.—Fee for special examination for the license in medicine, twenty guineas.

XV.—Fee for special examination for the license in midwifery, five guineas.

XVI.—Fee for examination for the license to practice as a midwife and nurse-tender, one guinea.

THE APOTHECARIES' HALL, IRELAND.

THE ARTS EXAMINATIONS

Will be held at the Hall four times in the year—viz, the third Thursday in the month of January, April, July, and October, at the hour of twelve o'clock noon.

The examination for the *License* is divided into two parts:—

The first part comprehends chemistry, botany, anatomy, physiology, materia medica, and pharmacy.

The second—medicine, surgery, pathology, therapeutics, midwifery, forensic medicine, and hygiene.

THE PROFESSIONAL EXAMINATIONS

Will be held quarterly, on the first and second Monday in January, April, July, and October.

The first part on the first Monday, at eleven o'clock a.m., and on the Tuesday and Wednesday succeeding at the same hour.

Subjects—Chemistry and botany, Monday; anatomy and physiology, Tuesday; materia medica and pharmacy, Wednesday.

The second part, or pass examination, on the second Monday, at eleven o'clock a.m., and on the Tuesday and Wednesday succeeding at the same hour.

Subjects—Medicine and surgery, Monday; midwifery and diseases of women and children, Tuesday; forensic medicine and hygiene, Wednesday; clinical examination, Thursday.

The first three hours of each day will be devoted to writing answers, and afterwards there will be two hours to an oral and practical examination.

Candidates at the examination on anatomy are liable to be called on to perform dissections; and at the examination on surgery, to perform one or more operations on the dead subject.

Doctors of medicine and licentiates of a college of physicians who have also spent twelve months at practical pharmacy, may obtain the license by undergoing an examination—the former in surgery and pharmacy, and the latter in medicine and pharmacy. Licentiates of the London Society of Apothecaries must undergo an examination in surgery.

THE PHARMACEUTICAL SOCIETY OF IRELAND.

The above Society was instituted by the Pharmacy Act (Ireland) in 1875, 38 & 39 Vict., cap. 57. In that Act it is stated that whereas a great deficiency existed throughout Ireland, of establishments for the sale of medicines and compounding of prescriptions, and that great inconvenience therefore arises to the public, it is expedient to amend the Act of 1791 (the Apothecaries Act). A president (Sir Dominic Corrigan) and vice-president (Dr. Aquilla Smith), with a council of twenty-one men, were named by the Government to carry out the provisions of the Act. In 1878 Sir Dominic Corrigan resigned the presidency. The present president is Professor Theoburne, and the vice-president, Dr. Aquilla Smith. The pharmaceutical chemist is not allowed to prescribe, but must strictly confine himself to the

compounding of prescriptions. In this respect he differs from the apothecary. All persons who keep open shops for compounding prescriptions must hold the license of the Pharmaceutical Society or the Apothecaries' Hall. The society, according to their Calendar, which was corrected to the 31st December, 1880, had 187 licentiates. They hold evening meetings during the winter for the reading and discussing of pharmaceutical papers and scientific papers bearing on pharmacy. This society has power under their Act to prosecute persons illegally compounding.

MEDICAL SCHOOLS AND HOSPITALS IN DUBLIN.

The clinical hospitals of Dublin are 10 in number, exclusive of the Cork Street Fever Hospital, two lying-in hospitals, two ophthalmic hospitals, the Children's Hospital in Pitt Street, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies, while others again are without any special connection with any school. While, however, such affiliation of a school and hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital and any school he wishes.

The Names of the Professors, Lecturers, and Hospital Staff, of the following Hospitals and Schools are not included in this column, being found in the Advertisement of each Institution, in another part of this issue.

THE ROYAL COLLEGE OF SURGEONS' SCHOOL is situated within the walls of the College, who appoint Professors. The Professor of Physiology commences his course with a series of lectures on comparative anatomy. The dissecting rooms are large and commodious, and furnished with every necessary appliance for study. The staff of demonstrators has been added to, and some of its members are constantly present to assist students. A very spacious new chemical laboratory has been constructed in which the practical chemical course is carried out, and which is filled with every modern improvement. Medals and exhibitions to the value of £85 are given at the end of the winter session, and are open to all students who have attended the necessary lectures in the school. The introductory lecture will be delivered on Monday, October 31, at 1 o'clock, by Professor Macnamara. For further information apply to any of the professors of the College, or to Mr. John Brennan, at the College, who is the person authorised to enter names and receive fees.

THE CARMICHAEL COLLEGE OF MEDICINE AND SURGERY more than a year since was removed from North Brunswick Street to its new premises in Aungier Street, is now fully completed. As the buildings are entirely new from their foundation, the directors have been able to provide all the most recent improvements, and have spared no expense to render every department fully adequate to the requirements of the most advanced teaching of medicine and surgery. The School is most conveniently situated, being in immediately proximity to the Meath, Adelaide, and Mercer's Hospitals, and it is connected by its teachers not only with these hospitals, but also with those of the House of Industry, the Mater Misericordias, and the City of Dublin. We would direct attention especially to the dissecting-rooms, and to the physiological laboratory. The former are spacious, well ventilated, and admirably lighted from the top as well as from the two sides; the latter is completely furnished with every requirement for the practical training of students in physiological and histological research. Two scholarships, the "Mayne" and the "Carmichael," each value £15, and prizes to the value of £97 on the foundation of the late Mr. Carmichael, are offered annually. The Carmichael Scholarship is for students commencing their third year, and will be examined for in the last week in October. The examination for the "Mayne," and for the other prizes, will not be held until the close of the session.

THE LEDWICH SCHOOL was founded in 1810 by the well-known Dr. Kirby, and since then has fully sustained its prestige. Its name was bestowed upon the school as a tribute of respect to the late T. H. Ledwich, who sacrificed a life in an increasing effort to promote its welfare. It is situated in Peter Street, not five minutes' walk from the College of Surgeons, the Meath, St. Vincent's, Coombe Lying-in Hospital, and Mercer's Hospital, and in the same street with the Adelaide Hospital and the Carmichael Medical School, and ten minutes' walk from the Catholic University School, the School of Physic, and the City of Dublin Hospital.

THE CATHOLIC UNIVERSITY SCHOOL is situated in Cecilia Street, about ten minutes' walk from the University itself in St. Stephen's Green. Most of its professors are physicians and surgeons of the Mater Misericordias, St. Vincent's, or Jervis Street Hospitals, and its course of study qualify for admission to the qualifying examinations of all the licensing bodies. The University grants an Exhibition of £20, a gold medal, value £7, and class prizes.

MERCER'S HOSPITAL, William Street, founded A.D. 1750.—This hospital is situated in the centre of the metropolis, in the midst of a densely-crowded population, and its doors are opened at all hours for the reception of accidents and of acute cases. Dispensaries are held daily and are largely attended. Special instruction is given in cutaneous, infantile, gynaecological, and ophthalmic diseases. From the large number of accidents which, from its position, come to the hospital, students are afforded ample opportunities of rendering themselves familiar with the nature and treatment of disease in its various forms, and of acquiring dexterity in the dressing and manual operations of minor surgery.

THE MEATH HOSPITAL, which is also the public infirmary of the county of Dublin, containing 120 beds, and now in the 125th year of its existence, ranks among the oldest of the charitable institutions of this city. It is situated on the side southern of the city, upon about three acres of ground, formerly called "The Dean's Vineyard." The original Meath Hospital, situated on the Coombe, was opened in 1753. The foundation stone of a new Meath Hospital, on the Coombe (now the Coombe Lying-in Hospital), was laid out by Lord Brabazon, 10th October, 1870; this hospital was, in 1774, constituted the County Dublin Infirmary by Act of Parliament. The present building, in Heytesburg Street, was opened in 1822, since which time the building has undergone considerable enlargements and improvements. In 1830 the theatre for operations and lectures was erected. In 1852-53 the Collis Wards were added as a memorial to Maurice Collis, twenty-five years surgeon to the hospital. In 1865 the "Smyly Ward," built for the special accommodation of children, was opened by the Lord-Lieutenant, Lord Woodhouse.

CLINICAL HOSPITALS.

THE CITY OF DUBLIN HOSPITAL is situated in Upper Bagot Street, about ten minutes' walk from the Royal College of Surgeons and Trinity College. There are special wards for ophthalmic and aural diseases, on which subjects a special course of lectures is delivered. There is a special ward for diseases of women, and a course of lectures given on diseases peculiar to women; there is also a ward exclusively for children. The Drummond Wing is set apart for fever and other contagious diseases. Clinical assistants to the physicians and dressers to the surgeons are appointed from the most deserving of the class. Medical and surgical pupils are appointed by examination.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—Accommodation; Hardwicke Hospital, 120 beds; Whitworth Hospital, 88 beds; Richmond Hospital, 110 beds; total, 318 beds. These hospitals are visited each morning at 9 o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. Special instruction is also given on various branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There is a very large ophthalmic, aural, and dental dispensary, and the respective surgeons give instruction in these important subjects. Eight resident clinical clerks and the dressers are appointed each half-year, and provided with furnished apartments, fuel, &c., &c. These appointments are open not

only to advanced students as formerly, but also to those who are qualified in medicine or surgery. A house surgeon for the Richmond Hospital is elected biennially, and receives a salary. The Richmond Lunatic Asylum, containing 1,000 beds, adjoins these hospitals.

The ADELAIDE HOSPITALS, recently much enlarged, are in Peter Street, next door to the Ledwith School and within a few minutes walk of the Carmichael Medical College, the College of Surgeons, and the University. From the 1st of October the physicians and surgeons will visit the wards, and give instruction at the bedside, at the advertised hours. There is a large detached fever hospital and also wards for infants and children. Special hours are devoted to clinical instruction in the diseases peculiar to women, and students are individually instructed in the use of the stethoscope, ophthalmoscope, laryngoscope, and microscope. Three resident pupils are selected half-yearly. Prize examinations including examination for the Hudson Scholarship, £30 and a gold medal, and a senior prize of £10, and a silver medal, are held at the termination of the Session. The large dispensaries afford facilities for the study of eye, ear, throat, and cutaneous diseases, as well as of minor surgery and dentistry.

MATER MISERICORDIÆ HOSPITAL.—This is one of the largest hospitals in Dublin; it contains 230 beds; 50 beds are reserved for fever and other contagious diseases. A special course of lectures on fever will be given during the session. A ward has been assigned for the treatment of ophthalmic diseases, in accordance with the requirements of licensing bodies. The Leonard prizes, value of £30, will be given at the end of the winter session. Two gold medals will be given as special clinical prizes, at the end of the ensuing session. The Introductory Lecture will be delivered by Mr. Kennedy on October 31st.

ST. VINCENT'S HOSPITAL was established in 1834 by the Sisters of Charity, some of whom had studied the system of the Parisian hospitals, after which it was modelled. The hospital has 120 beds constantly full, and each sister has charge of about twelve patients. In connection with it is the convalescent home at Linden Grove, Blackrock. The clinical instruction in medicine and surgery is given by Dr. Quinlan, Dr. Mapother, Dr. Kehoe, and Dr. Cox. A special ward for the treatment of the diseases of women has been opened under the care of Dr. J. A. Byrne, gynecologist to the hospital. The ophthalmic department is conducted by Mr. D. Redmond. The resident officers consist of a house surgeon and two resident pupils. The hospital is visited daily at 9 a.m., and patients are admitted at 10 a.m. Accidents and urgent cases, however, are admitted at all hours. Special arrangements have been made to afford facilities to the students for the study of infectious fevers.

DR. STEVENS'S HOSPITAL containing beds for 250 patients is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, occupying a position in the centre of one of the busiest manufacturing districts of the city otherwise unprovided with medical institutions. Immediately adjoining is St. Patrick's (Swift's) asylum for the insane. There is accommodation for residence of two medical and six surgical pupils, besides whom the House Surgeon receives as House Pupils. The fees payable for the privilege of residence are twenty guineas, winter; fifteen guineas, summer six months, which includes the fee for hospital practice for the corresponding terms, and the students in addition to their rooms and furniture are provided with coal and gas. The hospital is easily accessible by two lines of tramway one of which terminates at the Kingsbridge station within one minute walk of the hospital.

JERVIS STREET HOSPITAL is one of the oldest established charitable institutions in Dublin, having been founded in 1721. It is situated in a part of the city not otherwise provided with hospital relief, and which, from its commercial character, supplies the hospital with an abundance of surgical cases. Its nursing arrangements are under the charge of a community of Sisters of Mercy. The hospital being found inadequate to the demands upon it, is in process of being rebuilt, and, when finished, will be one of the finest hospitals in Dublin.

SPECIAL HOSPITALS.

The Special Hospitals of Dublin are the Rotunda and Coombe Lying-in Hospitals, Cork Street Fever Hospital, Pitt

Street Children's Infirmary, St. Mark's Ophthalmic Hospital, the National Eye and Ear Infirmary, two Dental Hospitals, the Throat Hospital, and two Orthopædic Hospitals.

THE ROTUNDA HOSPITAL.—This well-known and time-honoured institution possesses a character as a school of midwifery which needs no comment. It is not, however, as generally recognised as it deserves to be, as also a great school of gynecology. The institution consists, in fact, of two distinct hospitals, viz., the lying-in hospital, into which some 1,200 cases of labour are admitted annually, and the Hospital for the treatment of diseases peculiar to women, into which some 500 patients are now admitted during the course of the year. The present master, Dr. Lombe Athill, as is well known, devotes special attention to this department of the charity. There is also a large extern maternity in connection with the hospital. Every facility is afforded for the study of the special departments of medicine to which the hospital is devoted, and both students and midwives are granted a diploma on passing an examination. The clinical clerkship, value £50 a year, tenable for six months, is adjudged, after open competitive examination, to many pupil who has attended the full course of instruction in the hospital.

COOMBE LYING-IN HOSPITAL.—This hospital, which was rebuilt and refurnished some few years ago, contains 65 beds. It was founded in 1826 by Mrs. Boyle, and was incorporated by Royal Charter in 1867, thus enabling its medical officers to issue diplomas qualifying the holders to practise midwifery. This hospital is situated in the centre of a district densely populated by the lower orders, and thus affords the simplest opportunities for practice. It receives about 800 labour cases within its walls, while those attended as extern amount to more than double that number. Moreover, the chronic hospital for the reception of cases of the diseases of females gives admission to about 200 patients annually. The fee for attendance is £8 8s. for six months as extern, and £18 18s. as internal pupil. During that period the student attends on given days and nights in each week, and takes charge in his turn of any case that may be admitted to the labour wards, or may call for his assistance outside. Two resident pupil midwifery assistantships, and a clerkship, are obtainable half yearly by all pupils who have obtained their midwifery diplomas from the hospital. Lectures are delivered in the hospital, and clinical instruction is given daily at the bedside. In fact, this hospital is now one of the first clinical hospitals (in this speciality) in Europe.

CORK STREET FEVER HOSPITAL AND HOUSE OF RECOVERY is the only special fever hospital in Dublin. It contains 240 beds, and is supported mainly by an annual Government grant, supplemented by voluntary contributions. A certificate of attendance on fever being now required of candidates for the license to practice medicine of the King and Queen's College of Physicians in Ireland, arrangements have been made whereby the exceptional advantages connected with this institution can be utilised for purposes of clinical teaching. When these arrangements are completed and sanctioned by the managing committee, due notice will be given by advertisement as to the hours of attendance, fees payable, and other details. All particulars may then be ascertained on application to Dr. C. Percoll Atkins, Registrar and Resident Medical Officer.

THE PITT STREET CHILDREN'S INFIRMARY, established 1821, is situated close to Mercer's Hospital and the College of Surgeons. It was founded to provide treatment specially for children, and to teach that special branch of disease. Dr. Moore and Dr. Churchill are the medical officers.

DUBLIN ORTHOPÆDIC HOSPITAL, 11 Usher's Island, containing 30 beds for the treatment of every class of deformities and the practice of orthopædic surgery. The Institution is under the management of Mr. Swan.

NATIONAL ORTHOPÆDIC AND CHILDREN'S HOSPITAL for the treatment of club foot, contractions and distortions of the limbs, spinal and other bodily deformities and all non-infectious diseases peculiar to children, 7 Adelaide Road, Dublin. Mr. Ormsby attends on Mondays, Wednesdays, and Fridays, Dr. Woodhouse on Tuesdays, Wednesdays, and Saturdays, from 10 to 11 o'clock, and gives clinical instruction on the intern cases. The hospital is capable of containing 30 beds, for the reception of cases of deformity and all other forms of surgical disease. There is a large general dispensary for extern patients held daily from 10 to 11. Operations are per-

formed on Fridays. Students and practitioners are allowed to attend the clinical instruction.

ST. MARK'S OPHTHALMIC HOSPITAL AND DISPENSARY FOR DISEASES OF THE EYE AND EAR.—This is the largest special ophthalmic hospital in Dublin, and was founded by Sir William Wilde. Clinical lectures on the mornings of Mondays, Tuesdays, Thursdays, and Fridays, at 11 o'clock, and operations are performed on Wednesdays and Saturdays at the same hour. An Ophthalmic Class meets at 4 p.m. on Mondays, Tuesdays, Wednesdays, and Thursdays. A surgeon resides in the institution, and receives a salary of £50, besides room, gas, coal, &c.

NATIONAL EYE AND EAR INFIRMARY.—This hospital is situated in Molesworth Street, and contains twenty-six beds for patients suffering from eye disease. It has been lately reconstructed, and the out-patient department newly built. Clinical instruction in diseases of the eye, including the use of the ophthalmoscope, is given daily by the surgeons at 11 o'clock. Operations performed at 12 o'clock. Instruction in aural surgery is given at 10 a.m. The certificate in clinical ophthalmology from this hospital is recognised by the board of T.C.D. and by the Council of the College of Surgeons in Ireland for the L.R.C.S.I. Students may enter their names for the three months' course any day from 1st October to 1st April.

THE DENTAL HOSPITAL OF IRELAND, 29 York Street, is now open to students, under the following conditions:—Students proposing to attend the practice of the hospital must show certificates of having attended two full years of surgical study in a recognised school. No student shall be permitted to operate until he has satisfied the professional staff of the hospital of his knowledge of the anatomy of the teeth and jaws. Students must engage to keep their appointments regularly, and to conform to such regulations as shall from time to time be made by the committee or professional staff. No certificate shall be issued to a student unless he shall have made satisfactory progress during his attendance at hospital, and it shall be competent for the committee or professional staff to withhold the certificate of any pupil for breach of the bye-laws of the hospital. The fee for attendance at the hospital, from 9 till 10½ a.m. daily for three months, has been fixed at £3 3s.

INTRODUCTORY LECTURES IN THE DUBLIN SCHOOLS AND HOSPITALS.

Royal College of Surgeons—Mr Macnamara; October 31st, at 1 p.m.
 Ledwith School—Dr W. Stoker; October 31st, at 12 a.m.
 Carmichael College—None
 Catholic University School—None
 Meath Hospital—Dr Foot, November 7th, at 10 a.m.
 City of Dublin Hospital—None
 Richmond Hospital—Dr Lyons, M.P.; November 3rd, at 10.30 a.m.
 Jervis Street Hospital—None
 Mervin's Hospital—None
 St. Vincent's Hospital—Dr Cox; October 27th, at 11 a.m.
 Rotundo Hospital—November 5th, at 10 a.m.
 Mater Misericordiarum Hospital—Dr Kennedy; October 31st, at 11 a.m.

IRISH PROVINCIAL SCHOOLS.

THE QUEEN'S COLLEGES.

THESE three important academic institutions are the special schools of the Queen's University. They will cease to have any such relation to a central examining body when the new Irish University holds its examinations and confers degrees. But they will be maintained, as hitherto, by a handsome Government grant, and the same curriculum as that heretofore adopted will be continued. The various exhibitions and scholarships will still be available. Each College has the disposal of about £450 per annum in scholarships. The curriculum is generally well adapted for preparation for the new University examinations. The Colleges are well adapted for high-class technical education, having lecture-rooms provided with every appliance necessary in the modern training of a medical student. The great want in the Colleges of Cork and Galway is a summer session. This necessitates the loss to the student each year of three available working months, and deprives him of his practical hospital work in the summer session, both general and special. The courses of lectures in the winter session must be diligently attended, no student obtaining a certificate who has not put in two-thirds of a course. The winter session commences on November 1st, and ends May 31st.

The scholarship examinations are held in October. A detail of the prizes and exhibitions in arts and medicine, the names of the professors, and other information will be found in the advertisements of this issue, and full details may be had on application to—

Belfast.—John Purser, M.A., Registrar.

Cork.—Alexander Jack, M.A.

Galway.—Edward Townsend, M.A.

TECHNICAL EDUCATION FOR IRELAND.

ROYAL COLLEGE OF SCIENCE, STEPHEN'S GREEN DUBLIN.

THIS College supplies a complete Course of Instruction in Science, applicable to the Industrial Arts, especially those which may be classed broadly under the heads of Chemical Manufactures, Mining, and Engineering. A Diploma of Associate of the College is granted at the end of the Three Years' Course. There are Four Royal Scholarships of the value of £50 each yearly, with free education, including Laboratory Instruction, tenable for two years. Two become vacant each year. They are given to students who have been a year in the College. The Chemical and Physical Laboratories and Drawing School are open daily for Practical Instruction. The Session commences on Monday, October 31st.

THE IRISH DIPLOMA IN DENTAL SURGERY.

DURING 1878, the Council of the Royal College of Surgeons in Ireland, under the authority of the Dentists' Act, created a new licence in dental surgery. The examiners consist of three Fellows of the College, three registered dentists, and the President, Vice-President, or other member of the Council of the College (summoned in rotation).

The Board has the absolute power to refuse the application of any candidate.

The examinations embrace the anatomy, physiology, surgery, and pathology, of the teeth, jaws, and surrounding parts, and mechanical dentistry; and shall be partly written and partly oral.

All candidates shall lodge at least one fortnight previous to each examination—

I.—A certificate of having attained the age of 21 years.

II.—Receipt for the fee of ten guineas.

No candidate shall be admitted to examination (except one supplemental examination to be held next month for those who have already entered their names) who has not pursued the following curriculum, and lodged with the registrar of the College at least a fortnight previous to examination:—

I.—A certificate of having attained the age of 21 years.

II.—A certificate of having been engaged during four years in the acquirement of professional knowledge.

III.—Certificates of character as above.

IV.—A certificate of having passed the examination in preliminary education.

V.—A receipt for the fee of ten guineas.

VI.—Certificates of having attended in a recognised school—one course of lectures on anatomy and physiology, two courses of dissections, with demonstrations, one course of lectures on surgery, one course of lectures on chemistry, one course of practical chemistry and metallurgy, one course of lectures on materia medica, and two courses of lectures on dental surgery, including dental mechanics.

VII.—Certificates of having attended general hospital practice for two winter sessions; and the dental department of a general hospital, or a special dental hospital, for a further period of nine months.

VIII.—A certificate of having been engaged during, at least three years, in acquiring a practical knowledge of dentistry, under the instruction of a registered licentiate in dentistry of one of the licensing bodies.

The examinations shall include all the subjects of the foregoing curriculum, and shall be partly written and partly oral, preparations, microscopes, and other appliances being used.

N.B.—Every successful candidate, previous to re-

ceiving the licence, shall declare that he will not advertise, or pursue any other unbecoming mode of attracting business, so long as he holds the license in dentistry of the College.

The dental hospitals of Ireland are—that in York Street, Dublin, respecting which information will be found under the heading "Special Hospitals;" and the Dublin Dental Infirmary, in Beesford Place.

MEDICAL EDUCATION IN SCOTLAND

THE UNIVERSITIES.

THE fees for the degrees in all four of the Scotch Universities are the same, viz: £15 15s., (£5 5s. being payable at each of the three examinations, C.M., £5 5s. (in addition to the fees of M.B.); M.D., £5 5s. (in addition to the fees for M.B., and £10 for Government stamp.

UNIVERSITY OF EDINBURGH.

This is a qualifying and teaching body, and has complete Faculties of Arts, Theology and Law, equally with Medicine. Prior to commencing medical studies the student must pass a preliminary examination in English, Latin, and arithmetic, the elements of mathematics, and the elements of mechanics. An examination in at least two of the following subjects is demanded before being admitted to a professional examination, in addition to the foregoing subjects, viz.: Greek, French, German, Higher Mathematics, Natural Philosophy, Logic, Moral Philosophy. The University confers three degrees, medical and surgical qualifications being granted—M.D., M.B., and C.M. The C.M. is not conferred unless the M.B. be taken at the same time. For the degrees of M.B. and C.M. four years of professional study must be completed after passing a preliminary education recognised by the Medical Council. A degree in Arts of any British University is held to supersede the preliminary examination. Of the four years of professional study, one must be passed in the University of Edinburgh, and another of such four years must be in some other university entitled to grant the degree of M.D. The M.D. degree is conferred on Bachelors of Medicine who have attained the age of twenty-four years, and who present a thesis to be approved by the Medical Faculty. The lectures of several extra-mural lecturers in Edinburgh, as well as those at the London medical schools, and such teachers in the provincial schools approved by the University Court, are recognised, subject to certain conditions. The total fees for graduation, including lectures, &c., are £107 18s. For regulations as to Scholarships see "Edinburgh Medical School Guide."

In Public Health.—The University confers two degrees, a Bachelor and a Doctor of Science in Public Health.

UNIVERSITY OF ST. ANDREWS.

This University confers the degree of M.D. (certain exemptions being made to ten practitioners yearly), M.B. and C.M. Two years of study of each candidate must be in one or more of the following Universities, viz., the University of St. Andrew's, Glasgow, Aberdeen, Edinburgh, Oxford and Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

The degree of M.D. is conferred on any registered practitioner above the age of forty whose professional position is such as to entitle him to that degree, and who shall, on examination, satisfy the examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred under this section to a greater number than ten in any one year. The examinations are held yearly, towards the end of April.

UNIVERSITY OF GLASGOW,

This is both a teaching and examining body. It confers three degrees, viz.: Bachelor of Medicine, Master of Surgery, and Doctor of Medicine. Before graduating the Student must have been engaged in medical study for four years, one of which must have been spent at the University of Glasgow, and the others at some university or school recognised by the Glasgow University. A *medicus annus* is constituted by two courses of 100 lectures each, or by one course of 100 lectures,

and two of 50 each. Two preliminary examinations must be passed, one before commencing study, and the other before appearing at the first professional examination. A degree in Arts (not honorary) exempts the student from these examinations.

Public Health.—A special examination is held in subjects relating to Public Health and a certificate granted by the University.

Bursaries tenable by Medical Students.—The Brisbane Bursary of £50 yearly, held for four years by a student of medicine who is a Master of Arts. The Walton Bursary, of £36 yearly, held by a medical student (a native of England being preferred) for four years. The Logan Bursary, of £16 yearly, tenable by a medical student for four years. Two Rainy Bursaries' value £20 per annum each open to medical students who have just completed the second year of professional study and tenable for two years. The Armagh Bursaries, three in number, amounting each to £25 yearly, for three years, open to students of divinity, law, and medicine, who have taken the degree of M.A. The Macfarlane Bursary, value £40 per annum, and tenable for three years, open to students who have attended the first session of their professional study in the University of Glasgow, and who have passed in all the seven subjects of the preliminary examination for M.B. The Marshall Bursary, value £17 per annum, and tenable for four years open to students entering the Medical Faculty, and awarded by competition on the subjects of the Preliminary Examination. The Lorimer Bursary, value £50 per annum, tenable by a medical student for three years.

UNIVERSITY OF ABERDEEN.

This University is entitled to confer degrees in all the Faculties, and is a teaching body as well. The curriculum of study is nearly the same as in the University of Edinburgh. One year must be passed at Aberdeen. Another of such four years must be either in this University or in some other University entitled to give the degree of M.D. With regard to fees, each Candidate for the degree of M.B. must pay a fee of £5 5s. in respect of each of the professional examinations. If he desires to be admitted to the degree of M.B. only he will not be required to pay any further fee, in addition to the £15 15s.; but on admission to the degree of C.M. he must pay a further fee of £5 5s., in addition to the fees for the M.B. degree. Besides the Royal Infirmary students have the opportunity of attending several other local institutions. Perpetual fee for hospital practice is only £6. The professional examinations are held twice in each year; namely, in April and July, directly after the close of the winter and summer sessions.

The Degree of M.D.—The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degree of Bachelor of Medicine, and is of the age of twenty-four years, and has been engaged subsequently to his having received the degree of M.B. for two years, in attendance in an hospital, or in military or naval medical service, or in medical or surgical practice. Provided always that the degree of Doctor of Medicine shall not be conferred on any person unless he be a graduate in Arts, or unless he shall before or at the time of his obtaining the degree of Bachelor of Medicine, or thereafter, have passed a satisfactory examination in Greek, and in Logic or Moral Philosophy.

THE COLLEGES.

Royal College of Physicians, Edinburgh.—This, like the sister College of London, is exclusively a qualifying body. In conjunction with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Edinburgh, this College grants a double qualification, and registerable as such. Each applicant for the professional examination must previously have passed one of the preliminary examination recognised by the General Medical Council. Exemption is made in the case of masters or bachelors of Arts, of any British University and certain recognised foreign Universities. Candidates who may have already passed the first professional examination of any body approved of by the College will, on completion of their studies, be admitted to the second part of the examination.

The Fellowship, is conferred only by election, and the candidate must at least have been a member of the College for one year previously, and have attained the age of twenty-five years.

The Membership is conferred on licentiatees of the College

or graduates of a British or Irish University, with whose knowledge the College may be satisfied, and who have attained the age of twenty-four years. After March 1882, except in certain cases having reference to the age of the Candidate all members will have to pass an examination in Medicine and Therapeutics, and in another branch of Medical Science, to be selected by the Candidate.

The Licence.—The regulations are nearly the same as those for the joint examination for the Scotch double qualification.

The professional examination will be divided into two parts, according to the following arrangement of subjects: 1. Anatomy, physiology, chemistry; 2. *Materia medica* and pharmacy, pathology, and pathological anatomy, practice of medicine, surgery, midwifery, medical jurisprudence, clinical medicine. No candidate will be admitted to the first examination until the end of his second winter session, or to the second until he has completed four years of professional study. The examinations will be partly oral, partly in writing. Qualified practitioners may obtain the licence by passing an oral examination in the subjects of the second examination.

Qualification in Public Health.—The College now confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 10s.

Fees.—The fee payable by a licentiate is £15 15s. In the case of unsuccessful candidates the fee is returned, minus the expenses of examination. The fee to be paid by a member is £31 10s. When a licentiate is raised to the rank of a member, he pays £21, or £15 15s., according to the date of his licence. When a member is raised to the rank of a fellow, the fee is £31 10s., exclusive of stamp duty, which amounts to £25. All candidates for the fellowship or the membership must lodge their fees and the amount of stamp duty payable at the time to Government with the treasurer, previously to presenting their petitions.

Royal College of Surgeons, Edinburgh.—Candidates for the diploma of this College must have followed a course of study in some University, or in an established school of medicine, or in a recognised provincial school.

Preliminary Examination.—All candidates for the diploma of the College must have passed the complete preliminary examination prescribed by the General Medical Council, and have their names inscribed on the register of medical students at the commencement of their medical studies. The preliminary examination of certain recognised bodies is accepted by the College.

Professional Study.—Candidates must have been engaged, during four years after the preliminary examination in general education, in professional study, which shall include not less than four winter sessions, or three winter and two summers' attendance at a recognised medical school.

Professional Examination.—The professional examination is divided into two, the one oral, the other written. The first examination embraces anatomy, physiology, and chemistry, and for this candidates may appear at the end of their second winter. The second examination embraces surgery and surgical anatomy; also medicine, midwifery, *materia medica*, and medical jurisprudence; and does not take place prior to the termination of the winter session of the last year of study.

The Fellowship is conferred only on candidates who have obtained a diploma from this College or from either of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, and who are twenty-five years of age. The election is by ballot, and three-fourths of the votes are required to be in the candidate's favour, and he has to subscribe certain bye-laws of the College. Fellows are forbidden to keep open shops, to be connected with secret remedies, or indelicate advertisements or publications.

The Licence.—The regulations are almost the same as those for the joint examinations conducted by the Colleges of Physicians and Surgeons.

Dental Diploma.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a university or an established medical or dental school, recognised by the College as qualifying for the diploma in surgery. This diploma may in certain cases be given after examination, but *sine curriculo*.

THE SCOTCH DOUBLE QUALIFICATION.

The Royal College of Physicians of Edinburgh, by a certain arrangement, grants conjointly with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons, Glasgow, after one series of examinations, a double qualification, two diplomas being given and registered under the Medical Act as medical and surgical qualifications, thus: Lic. Roy. Coll. of Phys. Edin. and Lic. Roy. Coll. of Surg. Edin., or Lic. Roy. Coll. of Phys. Edin. and Lic. Fac. Phys. and Surg. Glas., according as the case may be.

By the understanding subsisting between these bodies, the College of Physicians takes exclusive charge of the examination in medicine; and the College of Surgeons or the Glasgow Faculty, of that in Surgery; whilst departments common to both medicine and surgery are examined by a board in which each body is represented. Such arrangements as these were contemplated by the Medical Act, and authorised by Section XLX., and those under consideration were sanctioned by the Medical Council, 7th August, 1859.

Candidates having fulfilled the full curriculum are subjected to two professional examinations. Hereafter the preliminary examination must be passed before commencing professional study, and must be otherwise conformable to the regulations of the Medical Council.

Total fee for double qualification is £21.

Faculty of Physicians and Surgeons, Glasgow.—The Faculty grants a licence in Surgery and a fellowship. In conjunction with the Edinburgh College of Physicians it grants a double qualification. The regulations and fees are the same as the Edinburgh colleges.

School of Medicine, Edinburgh.—The lectures of this School qualify for the University of Edinburgh and the other Universities, and the Royal Colleges of Physicians and Surgeons, Edinburgh, London, and Dublin, and the other medical and surgical boards.

Total fees for double qualification, £95.

For further details, see "Edinburgh School Guide."

Minto House School of Medicine.—This School, a part of the Edinburgh Extra Academical School of Medicine, has been recently opened, but on account of the excellence of its teaching staff and arrangements, its success has been most rapid. In this institution the following means are afforded for practical instruction:—

The dissecting rooms are open daily, from 9 a.m. to 4 p.m. under the superintendence of Mr. Symington and assistants.

The chemical laboratories are open daily from 9 a.m. till 5 p.m. for instruction in practical and analytical chemistry, under the superintendence of Mr. J. Falconer King, Mr. Hunter and assistants.

The medical jurisprudence and public health laboratories are open daily, under the superintendence of Dr. Aubrey Husband.

The *materia medica* museum and laboratory are open daily, under the superintendence of Dr. Craig.

Clinical instruction in diseases of women and in the minor gynecological operations is conducted in the Western Dispensary and Obstetrical Museum, under the superintendence of Dr. Halliday Croom.

The pathological laboratory is open daily from 10 a.m. till 4 p.m., under the superintendence of Dr. Waller.

The physiological laboratory is open daily from 10 a.m. till 4 p.m., under the superintendence of Mr. James Hunter.

Clinical instruction in diseases of children, at the Royal Hospital for Sick Children, on Tuesdays, Thursdays, and Saturdays, at 11-30 a.m.

Clinical instruction in diseases of the ear at the Ear Dispensary, on Mondays and Thursdays, at Twelve Noon.

Clinical instruction in diseases of the skin, Royal Dispensary, on Wednesdays and Saturdays, at 1 p.m.

Clinical instruction in diseases of the throat, at the Western Dispensary, on Wednesdays and Saturdays, at 5 p.m.

The Dissecting rooms and chemical laboratories open on October 4th.

Royal Infirmary, Edinburgh.—Clinical instruction is afforded at this institution under the supervision of Professors of the University and the ordinary physicians and surgeons of the Infirmary. Special instruction is given on

diseases of women, physical diagnosis, and diseases of the eye. Separate wards are devoted to fever, venereal diseases, diseases of women, diseases of the eye, &c. The perpetual fee, in one payment, is £12; the annual fee, £6 6s.; half-yearly, £4 4s.; quarterly, £2 2s. Separate payments for two years entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointment.

Dispensaries in Edinburgh.—At these institutions students may take out the necessary practice required by the examining bodies.

Glasgow Royal Infirmary School of Medicine.—The winter session will commence on October 29th. Courses of lectures are given on all the subjects required by the licensing bodies for qualification, and lectures are also given on practical physiology, operative surgery, aural surgery, dental surgery, and diseases of the eye. During the summer, lectures on insanity are given by Dr. A. Robertson, and the City parochial asylum under his charge is free to students of this school. Students have unusual facilities for the study of anatomy, the supply of subjects being practically unlimited.

Class Fees.—For each course, first session, £2 2s.; second session and perpetual, £1 1s. Students who have attended a first course elsewhere can enter on the second course on payment of £1 1s. Anatomy, first winter session, £4 4s.; summer session, £1 11s. 6d.; second winter session, £4 4s.; afterwards the fee for lectures and practical anatomy is £1 1s. per session. Lectures on diseases of the ear, £1 1s.; with clinique to those who are not students at the Hospital, £2 2s. Clinique on dental surgery, free to students of the Hospital, to others, £5 one year, perpetual, £10. Lectures on diseases of the eye, £1 1s. Lectures on dental surgery, £2 2s.

Glasgow Royal Infirmary—Number of beds, 532. In addition to the ordinary medical and surgical wards, there are separate wards for the treatment of venereal diseases and the diseases of women; whilst diseases of the eye, ear, throat, and teeth are especially treated at the dispensary. Courses of clinical medicine and surgery are given by the physicians and surgeons, and post-mortem examinations are conducted in the pathological theatre by the pathologists, who also give practical instruction in pathological anatomy and histology.

Appointments.—There are five physicians' and five surgeons' assistants. The appointments can be held for six or twelve months, and are open to students who have passed all their examinations except the last, or to gentlemen who have a qualification in medicine or surgery. Clinical assistants, dressers, dispensary clerks, and pathological assistants, are elected from the students.

Fees for hospital practice and clinical lectures, first year, £10 10s.; second year, £10 10s., afterwards free. For six months, £6 6s.; three months, £4 4s.; Students who have paid 20 guineas at another hospital for its perpetual ticket are admitted six months for £2 2s., or one year for £3 3s. Vaccination certificate, recognised by Privy Council, £1 1s.

Anderson's College, Glasgow.—This is exclusively a teaching body. In addition to its offering excellent opportunities for acquiring a good medical education, instruction is given in the other branches of a liberal education, advantage of which might profitably be taken by medical students generally. The expenses of this institution are exceedingly moderate, the fees for all lectures and hospital practice required of all candidates for the double qualification of the Scotch Colleges being £48. Extensive opportunities for dissection are offered, under the guidance of the lecturer on anatomy. Several scholarships, &c., are offered by the College.

In connection with this College, there are five hospitals and dispensaries for special diseases, to all of which students are admitted.

The Summer Session at this College begins on the first Tuesday of May, and closes about the middle of July. A Lectureship on Aural Surgery has been established. Lectures on Dental Anatomy and Surgery are also given four times weekly. The fee for two years' hospital practice

required by the curriculum for the Dental Licence is £10 10s. Fees for Dental Lectures are £2 2s. each course.

Further particulars may be obtained on applying to Dr. A. M. Buchanan, Dean of the Medical Faculty.

Dental School and Hospital, Edinburgh.—The hospital practice and lectures qualify for the dental diplomas of the Royal College of Surgeons, England, Royal College of Surgeons, Edinburgh, and Royal College of Surgeons, Ireland. For further information, apply to James Robertson, 4 Lindsay Place, Edinburgh, or to Mr. W. B. Macleod, Dean of the School.

NOTICE.—The Editor desires to thank those gentlemen attached to the various Medical Schools for supplying him with the information from which the foregoing pages have been composed.

NOTICE TO READERS.—As this number is devoted exclusively to information necessary for students intending to join one or other of the various medical schools; and for those who, having passed their curriculum, are about to enter into the ranks of the profession, the ordinary matter which fills our columns is necessarily deferred till next week. Should any of our readers desire to present this number to a patient or friend who contemplates sending his son to a medical college, our Publisher will be happy to supply him with a duplicate free of cost.

ON THE PREVENTION AND TREATMENT OF POST-PARTUM HÆMORRHAGE. (a)

By THOMAS MORE MADDEN, M.D., M.R.I.A.,

Obstetric Physician, Mater Misericordias Hospital, Dublin; formerly Examiner in Midwifery, Queen's University in Ireland, and Assistant-Physician, Rotunda Lying-in Hospital, &c.

DEATH from flooding after delivery should be considered as a generally preventable accident, and in the more perfect midwifery practice of the future will doubtless be entirely unknown. In their zeal to contribute to their complete deliverance from what is still, with too much reason, an ever-present terror to obstetric practitioners, some eminent modern authorities, who advocate the employment of perchloride of iron and other remedies on the least appearance of post-partum hæmorrhage, appear to have an exaggerated idea of the frequency of severe flooding, and to forget that some slight loss of blood is a natural termination of labour. When due care is taken in the way of preventive treatment fatal hæmorrhage is a comparatively rare accident. Thus, in a practice of upwards of twenty years in various countries, tropical as well as European, and during my connection with the largest lying-in hospital in Great Britain, I have only seen one case of death from hæmorrhage after child-birth.

We may almost always obviate, although we cannot yet always arrest flooding. The majority of cases of post-partum hæmorrhage are met with in women who have previously borne children, and the probability of its occurrence is in proportion to the number of the patient's previous confinements. In the Dublin Lying-in Hospital, of 89 cases of this kind, in 65 the patients were multiparæ. In such cases when we have any reason to anticipate hæmorrhage, the membranes should be ruptured as early as possible during labour, so as to allow the uterus to contract

gradually and firmly; and a dose of ergotine, or a drachm of the fluid extract of ergot, should be injected hypodermically before the head comes to press on the perineum. As a prophylactic of hæmorrhage, the efficacy of a course of any astringent preparation of iron given during the last months of pregnancy is unquestionable.

Hæmorrhage after delivery, from laceration of the cervix uteri, is more common than was formerly the case. This arises from the abuse of the long curved forceps which is now too often needlessly resorted to before the full dilatation of the os. Hence I am of opinion that in this way the abuse of the long forceps does as much harm as the use of the short, straight forceps does good in judicious hands.

Reviewing my experience of the various modern methods of arresting flooding, I have found that the injection of hot water into the uterus in such cases is most uncertain in its hæmostatic action, and is only useful in cases of extreme depression of the vital powers from excessive hæmorrhage, and after the failure of other remedies. Neither is the injection of cold or iced water to be depended on. The injection of a strong solution of perchloride of iron, although generally effectual as a styptic, is so hazardous, from the risk of its causing metro-peritonitis, that I now seldom resort to it. But I strongly recommend what I regard as a most effective and comparatively safe method of arresting post-partum hæmorrhage—namely, the introduction of a sponge soaked in a solution of the perchloride of iron which is to be passed into the uterus (grasped in the accoucheur's hand), and retained there until a firm contraction is produced, by which the sponge and the hand in which it is held are expelled together from the uterine cavity, and the flooding is stopped. At the same time I would desire to lay great stress on external manual pressure over the uterus in all cases until contraction is produced, on account of the possible danger of thus introducing the hand into the uterus, unless when rendered necessary by severe hæmorrhage. With regard to the treatment of collapse from hæmorrhage after delivery, I regard transfusion, as now practised, as almost useless in the great majority of cases of the emergency for which it is recommended. Instead of transfusion, I would advocate

(a) Abstract of Communication to the International Medical Congress, August, 1881.

the hypodermic injection of large doses of sulphuric ether, as suggested by Von Hecker, the soundness of which deduction is amply proved by a reference to the history of some remarkable instances of the good effects of this remedy in apparently hopeless cases of collapse from post-partum hæmorrhage.

ON HOLDING THE BREATH WHILE IN IMMEDIATE CONTIGUITY WITH THE PATIENT, WITH THE OBJECT OF LESSENING THE CHANCE OF CONTAGION. (a)

By HENRY MACCORMAC, M.D.,
Consulting Physician to the Belfast Royal Hospital.

DISEASES termed infectious, and propagated by miasma from man to man, are communicated, and only communicated, as I believe, by inhalation. Avoid the inhalation of the miasma of disease, and you may prevent the transmission of disease. If we assume the aggregate area of the lining of the lung air-cells to amount to 40 square feet, we see at once what an enormous avenue to the admission of the germs of disease is thus furnished when brought into such close proximity with the circulating fluid. If we arrest for the moment the act of respiration, we may also, in so far, arrest the transmission of disease. If the proposition I set forth, namely, that infectious disease is communicated by inhalation, be proved correct, a greatly increased measure of safety for all who have to deal with such, that is to say for physicians, nurses, relatives, and, in a sense, at one time or other, the entire community, is obtainable.

The poison of infection, when adequately diluted, does not by inhalation communicate disease. Take, for example, a case of plague or typhus, or Asiatic cholera, or scarlet fever, or diphtheria. In the immediate proximity of the patient, the poison is highly concentrated and highly communicable. At a certain distance, so that the poison shall be adequately diluted by admixture with pure fresh air, it ceases to be communicable. By sufficient ventilation, the poison of infectious disease is rendered, in fact, incommunicable. In a long experience, I never saw the poison of fever, when I had the control of the ventilation, transmitted from the sufferer to another person. I have seen typhus fever actually extend to nine persons in one household, when ventilation, or air renewal, was not attended to. Dr. Jackson, when dealing with the plague in Morocco, prescribed for the patients with entire personal immunity, from an open window, elevated but a few feet above them.

I have myself had much to do with Asiatic cholera, and always held my breath when in immediate proximity with the sufferers. I never experienced the malady, though every one associated with me, nurses and medical men alike, suffered more or less. For years, I had charge of a fever hospital, and was never attacked by typhus fever, though all the doctors, whether predecessors, associates, or successors, had it. The hospital nurses, without exception, suffered. In private practice, I enjoyed the same security, and I have attended typhus fever in the severest forms, and in the vilest and worst ventilated abodes.

A French physician, M. le Dr. Laval, médecin major des hopitaux, it is stated in the *Moniteur de l'Armée*, August, 1874, finding himself on leave in the regency of Tripoli, and hearing that the plague was raging at Merdj, about 20 hours' journey from Bengazi, repaired thither, and without medical co-operation, devoted himself without remission to the aid of the terrified population, preventing the malady, indeed, from spreading, but, to the infinite regret of every one, falling at last a victim to his own superb humanity. This admirable person, I believe, would not have perished, and multitudes of others might

(a) Communicated to the International Medical Congress, August, 1881.

have escaped likewise, had he and they, as I did, held in the breath, taking in a good cheastful beforehand, while immediately contiguous to the sick. I am anxious not to exaggerate the value of the precaution whose adoption I urge.

I simply state my own convictions and experience, and leave them for the consideration and adoption, should they haply approve, of the noble profession of which I am an humble member.

OPIUM AS A LUXURY, AND IN THE TREATMENT OF DISEASE.

By HERBERT PARSONS, M.R.C.S.,
Formerly Resident Medical Officer St. Mary's Hospital, London.

(Continued from page 230.)

Some persons there are on whom the same dose of opium will always produce the same effect, notwithstanding the length of time he may have been daily taking it; while too, some are peculiarly sensitive to it; so much so, that they may be brought to a precarious state by a dose that would hardly affect an ordinary individual. It will be well to analyse as far as possible the different class of persons as regards the operation on them of opium, without referring at present to the effects of disease in modifying its action, which will be considered later on.

Now, the administration of this drug may be desirable, either to produce its results on the brain or on some other organ. But the various actions of this complex substance must be borne in mind, otherwise the good produced on one organ may be overbalanced by the harm done to another; thus while we avoid Scylla we fall into Charybdis. Thus, before we can form an opinion as to any particular person's capacity for taking opiates we must have an eye to the condition of those organs which it affects; more especially, the kidneys and the lungs. Women, though highly sensitive to its action, yet generally take it well, and it will generally act as a hypnotic and soporific remarkably well without being followed by such disagreeable results as in men. Yet there are some, and not a few, whom opium will only excite, these are not generally women of nervous temperaments, so much as those of a phlegmatic and bilious disposition. But perfect rest must always be insured after taking opium, otherwise women are almost sure to become excited rather than sleepy. Hence it is that opium eating is by no means uncommon among the female sex.

In the treatment of children's diseases there is no drug more useful than this, though of course it has to be used with the most extreme caution.

Among men, opium is often unable to be borne on account of its action in stopping the secretion of bile and intestinal fluid, thus producing constipation and reflex headache. It also causes constipation by lessening the peristaltic action of the bowels, and also renders the rectum less sensible to action.

If this only is the drawback it can be remedied by giving it with calomel in pill or ipecacuanha or aloes in solution; a saline mixture either with, or on the morning after it has been taken, is also of use. A common and effective plan to remove the headache, bad taste and constipation, is a seidlitz powder in the morning. All the ill effects will often pass away after taking some exercise, or a cup of coffee, or something to eat. But, without notable disturbance of the digestive organs, opium produces a metimes headache after the drowsiness it has caused has passed off. Whether this headache is due to disturbance either of the circulation of molecular elements of the brain or to some poisonous principal retained in the blood is uncertain, but it is certain that headache is often the result of opium (more especially of a large quantity) without any other demonstrable derangement being present. Bromide of

potassium, quinine or theine-containing substances, are almost sure to cure it, and it may be prevented often by the simultaneous antecedent administration of bromide of potash. It is also sometimes an inconvenience, that the action of opium lasts so long at times; after a dose at night drowsiness will continue all the next day, this is more likely to be the case if constipation occurs at the same time.

To one in great pain, or in a state of great restlessness or excitement we may usually give a large dose without any apprehension. The amount of opium a woman in labour can take is a good evidence of the effect of pain and excitement in modifying its action. But with men of sanguine temperament and with little physical or mental pain opium has to be regarded with great care. There will always be in practice some persons met with on whom this drug will produce abnormally severe symptoms, either reducing them to a state of profound and alarming sopor with stertorous breathing, or producing so violent an excitement as almost to amount to delirium. Consequently, we must, if possible, try our man with a small dose to begin with, so that we avoid danger and find that we must resort to other sedatives, though there are some persons met with who can bear no kind of sedative.

It is seldom that opium will produce in small or moderate doses, a deep, dreamless, unbroken sleep; but on the contrary, the sleep produced will last either four or five hours, and afterwards be followed by transient dozes in which perhaps vivid dreams occur, or else the night will be interrupted six or seven times by a few minutes of consciousness, followed by relapses into deep sleep. This must be remembered, for patients, if they wake several times, even for a very short time, during the night are very apt to imagine and say that they have hardly slept at all, and will tell you they have passed a bad night, when in point of fact they have slept nine-tenths of the time. Very frequently it will be found that people tired out with brainwork and feeling weary are yet unable to sleep, a small dose of opium with, or without, some alcoholic beverage, will often be found to give the necessary inducement to attract sleep, and give rest.

It will be well now to go over in detail, as far as our present knowledge extends, the action of opium on the various structures and organs of the body.

Chemists have for many years laboured at separating the various alkaloids, acids and other constituents which make up the compound body known as opium. They have succeeded in finding and naming numerous alkaloids; and physiologists have taken up the labour and tried to determine their separate actions on the body. But it must be confessed that there is great discrepancy between the statements of different observers, and, with the exception of morphia none of the separated alkaloids have come much into use. One cause of this uncertainty is, perhaps, the difficulty of obtaining the alkaloids pure and unmixed, and another is the difference of the animals used in the researches, some physiologists experimenting on some sorts and some on others.

Opium is primarily a stimulant, both to the heart and to the nervous system.

Thus, on the heart it acts by quickening and strengthening the beats and rendering thus the systemic vessels more full of blood; this increase of action gradually dies off as the effect of the drug diminishes, but there does not follow, as after alcoholic stimulation, a period of depression.

On the brain its first effect is to produce increased functional activity, and perhaps stimulation and excitement, followed usually by blunting of its sensibility and sleep. But the effect varies much according to circumstances and according to whether the system is accustomed or not to it. The excitement stage may be long and the sedative stage short, or *vice-versa*.

Opium possesses also a certain tendency to produce con-

vulsions; and it may induce them either by its action on the brain or on the spinal cord. So opium produces cerebral anæmia, and in this state, especially if it is suddenly produced, convulsions frequently occur; while on the other hand we know by experiment that morphia will produce convulsions in frogs and other animals whose brains have been removed.

The sympathetic system of nerves and the vaso-motor nerves we must assume to be mostly depressed or paralysed by opium, but to be stimulated in some parts; thus, the cutaneous blood vessels all over the body and the arteries are dilated and full of blood; it also stops the peristaltic action of the bowels and even paralyses the muscular coats of the bladder and of the bronchial tubes, but the blood-vessels of the brain are contracted and that organ is thus rendered abnormally bloodless; the mucous membranes are made pale and lack their normal secretion, and as the secretory organs generally are rendered less active, we may assume that the blood vessels in them are contracted and do not carry so large a blood supply as usual to them, some authors say that if the dose is large the depressant effect on the vaso-motor nerves is marked from the first, but with a small dose is preceded by stimulation. Opium has other curious effects on the nervous system, such as the violent pain immediately produced across the abdomen, and at times vomiting, sometimes the face grows pale and syncope either takes place or is threatened, this, however, though not unfrequent after morphia injections is not often seen from the internal administration of the drug.

We can see then how opium by determining the blood to the skin may act as a diaphoretic, but in the same way we see how it is that all other secretions of the body are diminished; not only are the urinary, the biliary, the gastric, and other normal fluids lessened in quantity, but abnormal discharges such as bronchorrhœa gonorrhœa, and diarrhœa are also stopped.

When taken with, or about the time of a meal, the digestive process is very much delayed, not only on account of the lessened quantity of digestive secretions, but also on account of the decreased action of the walls of the stomach and duodenum; so that, sometimes after the lapse of many hours the food is vomited up in an almost unchanged state. The lack of bile in sufficient quantity produces constipation and that general feeling of heaviness well known by the public as biliousness, and evidenced by the pale-coloured fœces which sometimes remain in that condition for days. In some people these effects are most marked and last several days, in others they are not felt on one only. In some cases diarrhœa is produced, probably by nervous influence, those who are acted on thus are not usually troubled by uncomfortable after-consequences, but this is not always the case.

The respiratory centre is rendered less sensible to impressions by opium, and therefore the respirations are reduced in frequency; it is through this way that death usually comes about, though sometimes it is by syncope.

It acts sometimes, and as a primary result, as an exciting agent to the spinal cord, but finally it always results in depressing. The reflex and other functions of the cord are checked by it, and the conductive power of both the afferent and efferent nerves is diminished in force and rapidity; pain or any impression from a peripheral point is felt less distinctly, and after a longer interval than usual, from the moment of its production, and for the same reasons all movements involving reflex or automatic action are carried out with less quickness.

Opium reduces the normal activity of the non-striated and striated muscles and also stops an abnormal degree of muscular action producing spasms. Thus colic, spasm of glottis, spasmodic stricture of urethra and often asthma, yield readily to it.

Medicinally, all these properties make this drug of the

greatest and most varied kind of service, as it can be always relied on as certain to produce some effect, and if skillfully used to produce the effect which we desire.

There are so many forms in which opium and its active principals can be given, that it is a matter of considerable importance to select the best one for each purpose. Solid opium is generally the most reliable and certain form, and is not so variable in strength as fluid preparations; this is a good form to give it for most purposes, but more especially when the bowels or stomach are the parts to be treated, it is somewhat slow in this way, generally thirty to forty minutes elapsing before its effect begins to be produced, and some hours more before the maximum effect appears. Laudanum is useful when the fluid form is desired, it is more stimulating and more rapid in its action; acquiring its maximum effects in from a quarter to a half hour, often sooner; this preparation is more liable, however, to upset the digestion, and the strength of the solution is rather variable. Dover's powder is a good and highly scientific preparation, and scarcely ever produces in moderate doses gastro-intestinal derangements; it is also a good diaphoretic preparation, and especially to be employed in catarrhal cases, the worst of it is that it is an inconvient form to take, and that when kept long it sometimes loses its strength. There are numerous other preparations some scarcely necessary, and some specially prepared with other potent drugs with a view to act on special parts. Morphia is a useful salt, as containing the active principal of opium in a small bulk, and it is very difficult to discriminate between its action and that of the crude drug; it is said to be not so stimulant or astringent and not to produce such bad after results, but this is difficult to accept. It is much used, especially by injection hypodermically.

Hypodermic injection of morphia is quite a modern improvement, and it may be well to consider what cases call for its employment preferably to other means. There are two great advantages in this method, firstly, it acts at once, and secondly it acts with certainty. Thus in cases of hæmoptysis and violent delirium and acute pain of any sort its use is at once followed by an effect; no surer remedy can be used for hæmoptysis, for it at once controls the cough and restlessness, themselves the causes of the continuance of bleeding. In asthma and renal colic where immediate relief is absolutely required, injections are far better than any internal remedy. Then again, for the second reason, because by this method the morphia is bound to enter the blood, it is often the only, as well as the best, way in cases where the absorbent power of the stomach and intestines, or vomiting prevents any other form from producing an effect, such as in acute gastritis, reflex vomiting, diarrhoea and delirium tremens.

These are the chief if not the only advantages subcutaneous injection of morphia possesses over internal administration, and, on the other hand, it sometimes produces vomiting (almost always in women), faintness, severe pain in abdomen, and violent headache. The after effects too, are liable to be very disagreeable, sometimes more so, but at times less so than when taken by the mouth. The effects of the morphia are felt less than half a minute after the injection; perhaps it is this fact that the whole strength of the drug is felt at once, that makes vomiting and syncope, and even convulsions much commoner than when morphia is given in any other way.

Another thing must not be forgotten, that is the liability to inflammation ensuing at, and around, the point of injection, this does not usually go on to suppuration, but it does sometimes produce secondary lymphatic and glandular affections and even erysipelas. Some persons, too, will not bear the operation on account of the pain it causes, trivial though it be. From trial of all parts of the body, I have come to the conclusion that the abdominal wall is the best place to select for injecting, for here there is both less sensibility and

less liability to subsequent inflammation. In this situation I have never seen an injection followed by any notable inflammation even in persons in whom in other parts it is a usual consequence.

(To be continued.)

REMARKS ON SOME RECENT AND PRESENT VIEWS REGARDING FEVERS IN INDIA.

By Surgeon-General C. A. GORDON, M.D.,
C.B., Q.H.P., &c.

(Continued from page 229.)

DR SHARKEY (a), alluding to the views expressed by Dr. Collie as to the contagiousness of enteric fever, observes that, "this opinion is opposed to the pythogenic theory, which found so eminent an exponent as the late Dr. Murchison, but in no way incompatible with the more usually accepted etiology which maintains that the *poison* ordinarily enters the system by means of air and drink contaminated with the excreta of persons suffering from the disease." Dr. Sharkey believes that the *poison* resides "mainly, if not exclusively in the excreta." He is of opinion that as a result of disinfection of excreta there is an absence of epidemics of enteric fever in hospitals, and so few cases of attack occur among nurses and attendants; also that whether in hospitals or private houses a difficulty meets us as to the origin (on the specific theory) of the first case in a given locality. He quotes the views expressed by Drs. Wilks, Peacock, Bristowe, and Holmes regarding the theory of contagion of the disease, and expresses his own opinion "that when enteric fever originates in a hospital, as a rule there is something radically defective in the sanitary arrangements; and that either the air or drinking water is polluted by decomposing excrement;" these views having also support by Dr. Bristowe. Dr. Peacock records the case of a nurse who, he thought, had probably contracted typhoid fever by contagion.

Dr. Shirley Murphy (b), discussing the question of contagion of enteric fever in England, states that in a period of twenty-four years, in which 5,569 cases of this disease were treated in the London Fever Hospital, eight attendants on patients suffering from it were attacked, while seventeen employed otherwise in other parts of the buildings also contracted the disease. In Homerton the incidence of the disease was upon laundry maids and attendants upon patients—a circumstance attributed by Dr. Collie to the youth and thus more susceptible age of these persons. On the subject of causation of the disease by emanations from drains, Dr. Murphy writes, "It is clear, therefore, that there is no point of agreement between Dr. Collie and myself concerning the conditions under which enteric fever can arise from drains."

This difference of views in London, and yet opinions regarding the forms of disease called enteric fever in India have resulted in severe criticisms of the exponents of those opinions, although their correctness has not been successfully assailed.

Dr. McNeill (c) adverts to the great differences existing with regard to the etiology of typhoid fever. He describes an outbreak of the disease in the island of Colonsay due to infection from a servant girl sent home from the Bridge of Allan suffering from the disease and the spread of it from her to six families. In regard to all those families the water supply was good and obtained from different wells; each had their own cows; there were no sewers, and when the disease occurred excretions were disinfected and buried at safe distances. The first family affected was that of the servant girl

(a) *British Medical Journal*, 6th November, 1890.

(b) *Ibid.*

(c) *Ibid.*

alluded to; the first member of the second family was a friend of hers who visited and nursed her; the third used to call daily at the house to inquire; the fourth became infected through the third. The conclusions he accordingly arrives at are: 1. That the exhalations from the lungs, skin, urine, or fresh evacuations must be infectious. 2. That there is danger of infection for some time after diarrhoea has ceased. 3. Persons over thirty years of age are less susceptible than those under that age. 4. The period of inoculation was in one case twenty or twenty-one days.

Dr. Donkin (a), in support of the contagiousness of typhoid fever, instances the occurrence of the disease in three young women, nurses in the Hospital for Children, Shadwell. In these the affection declared itself "within a few weeks after the nurses had begun to tend enteric patients;" they had, however, "been exposed to the chronic influence of bad drainage" for some time previously, namely, two for many months, one for at least two years. During that period numerous cases of diarrhoea, sore throat of great severity, and *nondescript* cases of pyrexia, had prevailed under the name of Shadwell fever, yet the only cases of enteric fever which arose in the hospital were those of the two nurses above alluded to. Dr. Donkin observes that while these insanitary conditions affected all the inmates alike the only ones seized with enteric fever were the nurses who had attended cases of that disease. He remarks in reference to them that "the drain theory, supported as it is by a great cloud of no mean witnesses, has an authority somewhat out of proportion to the amount of strict and unbiassed reasoning in which it rests."

Dr. Bruce Low (b) writes of enteric fever in country places in England. In the district to which he refers the population is agricultural, and scattered; in the isolated farm houses there are no sewers, the water supply is pure, from springs; the geological formation white limestone. During eight years only one case of enteric fever was due to drinking contaminated drinking water. The milk supply was easily watched; most of the cottagers kept their own cows; he had traced no case of contaminated milk nor has he heard of any cow, calf, or pig suffering from a disease like typhoid in his vicinity; he has traced no case to eating diseased or putrid meat. In giving particulars of four cases of enteric fever he observes that, "neither sewer gas, contaminated water supply, nor exposure to direct infection had anything to do with their origin." One case occurred in a young man, dirty in his habits, and for a considerable time subject to diarrhoea; his cottage was damp, dirty, and overcrowded; the garden privy in bad repair, filth level with the seat, smell very bad; emanating from this case four others occurred. Dr. Low asks if this is a case of development of enteric fever *de novo*, or one of progressive development of infectiveness from diarrhoea according to the theory of Dr. Burdon Sanderson "that it is possible to proceed from an inflammation of a purely non-infective origin to the artificial induction of a process of the most intense virulence?" and he adds, "I know that a foul and overflowing garden privy can produce a contagious diarrhoea;" and he adduces cases in confirmation of this view. He instances a case in which enteric fever was induced by eating tainted American bacon; in it he says the putridity of the bacon may have developed a putrogen which gave rise to a filth fever identical in all respects with typhoid. It has been asserted that specific contagion of typhoid fever has been received through "tramps." Dr. Bruce Low in eight years has not seen one case among that class of persons, nor has he met with any in a common lodging house with the exception of one child permanently residing in a house of that description situated close to a slaughter house.

He confesses that, although favourably situated for tracing the origin of fever cases he has met with great difficulties—that is doubtless as a result of pursuing researches with sole reference to the pythogenic theory of causation. He gives the testimony of his neighbouring medical friends as "distinctly in favour of the *de novo* origin of the fever." He admits that under certain insanitary conditions the fever may be bred much in the same way as *pyrogen*, although the large majority of cases do arise from contagion, these being the views held by Trousseau. He quotes from Niemeyer as to the occurrence of abdominal typhus in places far removed from travel where no case has occurred for years and where there is no suspicion of contagious origin. He notices the fact that abdominal typhus occurs *sporadically*, and often as house epidemics in localities where quantities of animal matters are decomposing. Quoting from Dr. Murchison as to the proposed disuse of the words *typhoid* and *enteric* and the substitution of the term *pythogenic* fever, also from Dr. Parkes that "although the origin of typhoid merely from putrefying non-typhoid is not considered to be probable it is not disproved, and it is certain that the disease may spread by sewers and faecal decomposition." He quotes from Dr. Alfred Carpenter that "enteric fever arises apparently *sub sponte*;" also from Dr. King, "that it may be produced *de novo* by the putrefaction of albuminous stools;" and the adverse opinion of Dr. Cayley "that the weight of evidence is against the *de novo* theory," but adds "that the evidence has only been heard on one side as yet;"—in reference to which statement I would add an expression of hope that a fair exposition of both sides of the important question at issue may obtain admittance into the pages of the medical journals. (a)

Dr. Herbert Metcalfe (b), of Norfolk Island, gives details of a case of what he considered "enteric" fever, originating *de novo* from the use of water of a well contaminated by decomposing animal matters, but of non-specific character. Prior to the occurrence of that case there had been no enteric fever in Norfolk Island for a period of fifteen months; the subject of attack had only arrived in September and became ill in January; he was the only person who had drunk water from the well in question, but no mention occurs in the record of other conditions or influences, general or individual—only this one item, water.

Dr. Walter Bernard (c) dwells upon the difficulty of diagnosing enteric fever, that difficulty arising from "the fact that typhoid exhibits many protean forms, and closely resembles many other morbid states." He observes that "many cases which some years ago would have been classed under the heads of simple continued fever, low fever, worm fever, infantile remittent fever, gastric fever, bilious fever, and *such like* would now be placed under the head of enteric fever." That is, cases differing from each other absolutely in respect to their etiology and phenomena would now be included under the one term, enteric; so that medical officers who in India similarly extend the significance given to a name have high authority for so doing. But Dr. Bernard is of opinion that we err in using the term typhoid in respect to too many acute febrile states. As an illustration he mentions a case in which in 1860 Zenker proved by post-mortem examination that trichinosis, not typhoid fever as stated, was the cause of death; he believes that during epidemics of typhoid fever cases occur exactly like those of acute febrile gastro-enteric catarrh; and he mentions that "many high authorities

(a) *Apropos* to this I would tender my acknowledgments to the editors of the *Practitioner*, *Medical Press and Circular*, *Medical Times and Gazette*, and *Lancet*, for courtesy in admitting papers by me on the subject of fevers in India as affecting British troops.

(b) *Ibid.*

do not regard the well-known outbreak at Clapham School as typhoid, but as *some other disease*, still unnamed, produced by sewage." On the subject of *temperature* he quotes from Dr. Cayley that "it has been proved beyond all doubt that a patient may pass through typhoid without his temperature rising above normal; that Jenner and Murchison have shown the rule laid down by Wunderlich is unreliable;" and of this Dr. Bernard says we have evidence in the occurrence of "cases of *non-febrile typhoid*." Regarding phenomena he observes that "mild cases of typhoid, typhus, simple continued fever, and febrile gastro-enteric catarrh may present to us exactly the same clinical phenomena." "As to eruption," he says, "the rash of typhus occasionally, when discrete and in its earlier stages, resemble an abundant typhoid eruption;" then allusion is made to cases in "what is called the typhoid state is present," as to the difficulty in determining whether such are due to the presence of typhus or typhoid poison. Quoting from Murchison (page 472), he says, "that many cases of septicæmia due to caries of the temporal bone resemble closely enteric fever." He states that "acute tuberculosis, whether pulmonary, meningeal, or abdominal, closely resembles typhoid," that we may have all the symptoms of tubercular meningitis present in typhoid; that in cases of extreme difficulty "we must content ourselves to remain in doubt until *post-mortem* examination solves the problem." As to local diseases, he remarks that "sometimes, especially in children, it is difficult to come to a conclusion whether the pyrexia is due to some local affection (*e.g.* intestinal irritation, enteritis, pneumonia), or whether it is primary." With regard to treatment, he observes, "quinine as an anti-pyretic agent has much influence in typhoid, whereas in tuberculous affections it has little or no effect" (p. 473).

Taking these remarks in connection with what has already been adduced in my several notes on fevers it seems fair to ask, wherein, then, lies the difference between the characteristics of the typhoid, or enteric condition, or complication occurring in the course of the several diseases named, other than fever, from those that distinguish the particular form of fever to which those expressions are applied synonymously and in a specific sense? Wherein the difference between the phenomena occurring in the course of fever and taking place in the course of either of those diseases? So far as any reply presents itself that reply is, None whatever. Dr. Bernard is, no doubt, fully supported by facts when he expresses his opinion that "we err in using the term typhoid in respect to too many acute febrile states." The remark regarding quinine as a test of typhoid as against tuberculous affections is important in reference to what has already been stated regarding this remedy.

(To be continued.)

Clinical Records.

GOVERNMENT CIVIL HOSPITAL, CEYLON.

Case of Ovariectomy—Operation—Recovery.

Under the care of Dr. F. VAN DER SMAGT.

THE subject of this case, Selindo, a weakly, anæmic Singhalese woman, married, and aged about 30 years, came first under my observation on the 7th April last, when she was admitted into hospital with ovarian dropsy, said at the time to have been of eight months' duration. She was spare, pale-faced, and with the typical "ovarian expression" of countenance. Her general health was very indifferent, her bowels were inclined to be costive, and there was total suppression of the menses; from some time before she observed her abdomen enlarging.

She was allowed a nourishing diet, and prescribed a mixture containing quinine, strychnia and steel. On her general

health improving, and after about five weeks' stay in hospital, she was tapped by me, and about 2½ gallons of thin, limpid fluid drawn off. She was apparently greatly relieved by this, and soon after took her discharge.

We lost sight of the patient for some months, but she came under notice once more on last July 28, with the tumour occupying the whole of the abdominal cavity, and to all appearances larger than when she was first admitted. It had begun to cause great inconvenience latterly from pressure, and the patient begged hard that something may be done to prevent her abdomen filling again. She was now admitted into hospital a second time, and after examining her, inquiring minutely into her previous history, and ascertaining the length of time the cyst took to fill again, it was diagnosed as a unilocular tumour and with scarcely any adhesions. Her general health was now pretty good, and with a fairly nourishing diet and some tonic medicine, it was found to have improved considerably after a short stay in hospital.

After the usual preparations had been made, it was determined to perform the operation on the patient on the 13th of August last, and on the morning of that day the patient having been put under the influence of chloroform by me, and assisted by the other medical officers at this station, Dr. Anthonisz, the colonial surgeon, who had previously operated successfully on similar cases, commenced the operation under the antiseptic spray, by making an incision, about 4 inches long, sufficient, in fact, only to enable him to introduce his hand—beginning a little below the umbilicus and exposing the abdominal cavity. The tumour having been brought into view, a Spencer Wells' trocar was introduced, and after some of the contents of the cyst had been drawn off, the trocar was plugged by a small cork to prevent any of the fluid escaping into the peritoneal cavity, and the neck of the trocar itself secured by a double ligature to the cyst. The tumour was now, from time to time, drained of its contents and gradually removed from the abdominal cavity. The only adhesion present, was one situated upwards and apparently to the transverse colon—this was carefully ligatured with a carbolised silk ligature, divided and dropped into the abdominal cavity, and the peritoneum secured over it with a cat-gut suture. All the antiseptic precautions recommended to be taken in these operations were, as far as practicable, done by us. Lister's spray being at play during the whole time the operator was busy with the patient and until she was dressed.

The pedicle in this case was not very long, scarcely 2 inches, wide and rather flat—it was secured, well ligatured, and the tumour cut off, the ligature attached to the pedicle being brought out through a small opening in the left groin, and slightly tightened, from time to time, to assist in the pedicle being detached. The hæmorrhage was very slight indeed, no vessel requiring to be ligatured. The cavity of the abdomen having been carefully sponged out with a carbolised sponge, the edges of the wound were brought together by some thin carbolised silk sutures passed through the entire thickness of the abdominal walls, and some superficial (skin) catgut and coir fibre sutures. The dressing for the wound consisted of folds of lint soaked in carbolic acid lotion, over which was placed a layer of carbolised cotton, some carbolised gauze, and over that again some strips of flannel and a binder over all. The patient having been administered an opium suppository, was well wrapped in warm blankets, and put to bed.

When seen in the afternoon she complained of some abdominal pain. Pulse, 5 p.m., 124; temperature, 101'4.

9 p.m.—Her urine had to be drawn off by catheter. Repeat suppository.

August 14th, 7 a.m.—Pulse, 120; temp., 100; passed urine herself this morning. Slept pretty well. Abdominal pains continue severe. Continue suppositories, t.d.

14th, 4 p.m.—Temp., 102'8; pulse, 130.

15th, 7 a.m.—Pulse, 112; temp. 102'8. Slept better than the night previous; abdominal pains less severe; stomach slightly irritable; vomited some bilious matter. Suppositories to be continued, b.d. Opii, gr. j. t.d.

4 p.m.—Temp., 101'6; pulse, 108. Takes nourishment (milk and broth) freely.

16th, 7 a.m.—Temp., 100'8; pulse, 108. Abdominal pains slight; no vomiting. Remedies to be continued.

4 p.m.—Temp., 100'8; pulse, 108.

17th, 7 a.m.—Patient comfortably; slept all night; hardly feels any pain. Pulse, 108; temp., 101'6. Continue pills, b.d., and suppository only at bedtime.

4 p.m.—Pulse, 108; temp., 101'6.

18th, 7 a.m.—Slept all night. Pulse, 104; temp., 100·8.
 4 p.m.—Temp., 99; pulse, 100.
 9 p.m.—Some difficulty in voiding urine, which had to be drawn off by catheter.
 19th, 7 a.m.—Urine drawn off again this morning. Pulse, 100; temp., 100·6.
 4 p.m.—Pulse, 104; temp., 101·2.
 20th, 7 a.m.—Feels more comfortable; urine passed freely since last night; bowels not moved since operation. Pulse, 104; temp., 102·2. Warm soap and water enema—stat.
 4 p.m.—Bowels moved freely, twice, after enema. Pulse, 96; temperature, 99·4. Continue pill only at bed time.
 21st, 7 a.m.—Slept well throughout the night. Pulse, 88; temp., 98·8.
 4 p.m.—Pulse, 88; temp., 98·2.
 22nd, 7 a.m.—No pain. Pulse, 80; temp., 98·2.
 4 p.m.—Pulse, 96; temp., 98·4.
 23rd, 7 a.m.—Pulse, 80; temp., 98·8.
 4 p.m.—Pulse, 76; temp., 98·6.
 24th, 7 a.m.—Doing well. Pulse, 80; temp., 98·4.
 4 p.m.—Pulse, 88; temp., 99.
 25th, 7 a.m.—Pulse, 88; temp., 99·6. A portion of the dressing over the abdomen and that over the groin, were changed under the spray—hardly any discharge.
 4 p.m.—Slight pain in the groin (pedicle). Pulse, 96; temp., 100·4.
 26th, 7 a.m.—Felt a little pain in groin at night—none now. Pulse, 88; temp., 100.
 4 p.m.—Pulse, 96; temp., 101·2. Bowels not moved since the 20th. Repeat enema; continue pill, h.s.
 27th, 7 a.m.—Feels more comfortable after the bowels had been moved by enema. Pulse, 84; temp., 100·6.
 4 p.m.—Pulse, 96; temp., 102.
 28th, 7 a.m.—Doing well. Pulse, 88; temp., 101·4. Slight discharge from wound in groin. Dressing changed again under the spray. Abdominal wound found to have united throughout its entire length.
 4 p.m.—Pulse, 96; temp., 103.
 This rise in the temperature was noticed each time the dressing was changed under the spray.
 The patient continued improving steadily after this, the pedicle coming away on the 11th September, after slight traction at the ligature, the wound in the groin closing up the next day. There was uninterrupted progress in the case of this patient until the 18th September, when she complained of a colic, which was so severe as to have prevented her sleeping that night. Her temperature the next morning (19th) was 98, and her pulse 104. She gradually grew worse after this, and with increased colicky pains, she suffered from great irritability of the stomach, her bowels remaining costive all the while.
 Her pulse on the 20th September was 112, but feeble; her temperature 98·2. Opil, gr. j. every fourth hour. Castor-oil and warm soap and water enemata. Low diet, with milk and brandy as extras.
 Sept. 20th, 8 p.m.—Still in pain. Hypodermic injection of morphia (gr. 1-6th), h.s.
 21st.—Vomiting continues, vomited matter to all appearances feculent. Pulse continues feeble, but quick; temperature below normal, 97·6; hiccough; bowels costive. Repeat enemata, opii gr. ss., ext. belladonnæ, gr. ʒ. M ft. pil. every five or six hours.
 4 p.m.—Feels slightly easier. Pulse about the same, temperature, 97·8.
 22nd, 7 a.m.—Slept pretty well at night. No hiccough. Stomach less irritable. Pulse less quick, 104; temperature 97·8. Repeat enemata. Continue pills, t.d.
 4 p.m.—More comfortable, one stool after enema. Pulse, 100; temp., 98.
 23rd, 7 a.m.—Improving slowly; no pain in abdomen; slept well at night. Bowels moved this morning without enema. Pulse and temperature same as previous morning. Continue pill only at bed time, omit enema.
 4 p.m.—Temp., 98·6; pulse, 96.
 24th.—Slept all night; feeling stronger daily. Pulse, 92; temp., 97·4.
 The patient now gradually regained her strength and appetite, and was able to move about the wards again. All medicines were now omitted, and care was exercised regarding the patient's diet for some time. Towards the latter end of the month she was allowed ordinary diet, and as she seemed anxious to return to her village, she was discharged early on the morning of the 4th October, when she left with her

mother and husband, and has continued to improve in every way according to the last account we have had of her.

Remarks.—In this case, the progress made by the patient from a few days after the operation, was very satisfactory until September 18th, when she complained of the colic, which has already been described, and which, for some days, caused us no little anxiety. With the exception of this single mishap, the patient may be said (considering the indifferent state of general health) to have made a very fair recovery.

Regarding the material used for the superficial (skin) sutures, it may be as well to mention how admirably those of ordinary coirfibre answered, these as Dr. Anthonis observed, were found to cause less irritation, and to be easier of removal than those made of other materials, particularly wire. They are, and have been, for some time used in this hospital with very satisfactory results, and will, I have little doubt, when better known, be preferred in most instances, generally, to other sutures.

In conclusion, we have to add our testimony to the benefit—in this case in particular—derived from the antiseptic dressings, and attending to them in detail, as recommended by Professor Lister, at least as far as it is practicable in our Colonial hospitals.

This was a patient who was under my care as surgeon of this hospital, during last year, and who after her return to her village, paid us a visit a few months subsequently, looking the picture of health, and much stouter than before her illness.

Special.

WOOL-SORTERS' DISEASE.

I.

TRADE has its romances, and there is no greater romance in its whole history than that connected with the introduction of Llama wool and alpaca into English manufacture. Dickens has immortalised the event. This historical incident is thus described (a):—

“In the year 1836 a huge pile of dirty-looking sacks, filled with some fibrous material which bore a strong resemblance to superannuated horsehair, or frowsy elongated wool, or anything else unpleasant or unattractive, were landed at Liverpool.

“When those queer-looking bales had first arrived, or by what vessel brought, or for what purpose intended, the very oldest warehouseman in the Liverpool Docks couldn't say. There had once been a rumour—a mere warehouseman's whisper—that the bales had been shipped from South America on spec, and consigned to the agency of C. W. and F. Fozzle and Co. But even this seemed to have been forgotten, and it was agreed on all hands that the three hundred and odd sacks of nondescript hair-wool were a perfect nuisance. The rats appeared to be the only parties who at all approved of the importation, and to them it was the finest investment for capital that had been known in Liverpool since their first ancestors had migrated thither.

“Well those bales seemed likely to rot, or fall to dust, or be bitten up for the particular use of the female rats. Brokers wouldn't so much as look at them. Merchants could have nothing to say to them. Dealers couldn't make them out. Manufacturers shook their heads at them; while the agents, C. W. and Fozzle & Co., felt quite savage at the sight of the invoice and bill of lading, and once spoke to their head clerk about shipping them out to South America again.

“One day—we won't care what day it was, or even what week, or month, though things of far less national importance have been chronicled to the very half-minute—one day, a plain, business-looking man, with an intelligent face and

(a) *Household Words*, vol. vi., 1853, p. 250.

quiet, reserved manner, was walking alone through those same warehouses at Liverpool, when his eye fell upon some of the superannated horsehair projecting from one of the dirty bales. Some lady rat, more delicate than her neighbours, had found it rather coarser than usual, and had persuaded her lord and master to eject the portion from her resting-place. Our friend took it up, looked at it, felt it, smelt it, rubbed it, pulled it about; in fact, he did all but taste it, and he would have done that if it had suited his purpose, for he was 'Yorkshire.' Having held it up to the light, and held it away from the light, and held it in all sorts of positions, and done all sorts of cruelties to it, as though it had been his most deadly enemy, and he was feeling quite vindictive, he placed a handful or two in his pocket, and walked calmly away, evidently intending to put the stuff to some excruciating private tortures at home.

"What particular experiments he tried with this fibrous substance I am not exactly in a position to relate, nor does it much signify; but the sequel was that the same quiet, business-looking man was seen to enter the office of Messrs. C. W. and F. Fozzle & Co., and ask for the head of the firm. When he asked that portion of the house if he would accept of eightpence per pound for the entire contents of the three hundred and odd frowsy, dusty bags of non-descript wool, the authority interrogated felt so confounded that he could not have told whether he were the head or the tail of the firm. At first he fancied our friend had come for the express purpose of quizzing him; then that he was an escaped lunatic; and thought seriously of calling for the police; but eventually it ended in his making over to him the bill of lading for the goods in consideration for the price offered.

"It was quite an event in the little dark office of C. W. and F. Fozzle & Co., which had its supply of light (of a very inferior quality) from the grim old churchyard. All the establishment stole a look at the buyer of the 'South American stuff.' The chief clerk had the curiosity to speak to him, and hear him reply. The cashier touched his coat-tails; the book-keeper, a thin man in spectacles, examined his hat and gloves; the porter openly grinned at him. When the quiet purchaser had departed C. W. and F. Fozzle & Co. shut themselves up, and gave their clerks a holiday.

"But if the sellers had cause for rejoicing, not less so had the buyer. Reader, those three hundred and odd bales of queer-looking South American stuff contained 'Alpaca wool,' at that date entirely unknown to our manufacturers, and which it would still have been but for the fortunate enterprise of one intelligent courageous man. That bold manufacturer was (the late) Sir Titus Salt, in those days a mere beginner, with a very few thousands to aid him in his upward career, but at his death one of the wealthiest amongst the wealthy men of Bradford, in Yorkshire. His fortune had been altogether built up by the aid of this same 'alpaca,' to the manufacture of which he devoted the whole of his time and energy."

Alpaca and mohair are inseparably associated with the name of Salt, and it is well worth a visit to the wonderful creation, which has sprung from the lucky discovery of the neglected three hundred and odd bags, discovered in 1836.

About four miles from Bradford there is a picturesque part of the valley of the Aire, and in this spot the introducer of alpaca purchased an estate, to which he gave the name of Saltaire, by the natural combination of his own name, with that of the river, on which his property is

situated. Here he erected the famous works, which are amongst the wonders of England.

The introduction of this wool into manufacture, though advantageous to the master, has not been without its alloy to the workman. Wool-sorters' disease has since been associated with the name of Van Mohair, and numerous deaths have been reported, caused by the picking and sorting of this wool.

In the *Medical Press and Circular*, April 10th, 1878, we spoke about the necessity of appointing a commission to inquire into this disease, and on November 17, 1878 we again returned to the subject, our persistence resulting in the appointment of Dr. Spears, Local Government inspector, for the task of making the inquiry.

The Bradford Medico-Chirurgical Society—one of those excellent societies which do so much good in elevating the tone of professional thought, and keeping the profession *au courant* with medical knowledge—also appointed a commission from their own members, to examine the evidence as to the association of this disease with the bacterium anthracis.

Dr. Spears has published his report. We must reserve our analysis of it to another number.

(To be continued.)

A DEFAULTING WATER COMPANY.

We have been furnished by the Water Examiner with a special report on the cause of failure on the part of the Grand Junction Waterworks Company to supply its customers with water during the hot days of July. The report clearly shows that the extenuating circumstances published by the Company, namely, that the failure was solely due to the bursting of a main, is no longer tenable. The water famine was, in fact, attributable to the utter carelessness of the Company, whose officers were aware that a deficiency of pumping power existed at Hampton, and which was utterly disregarded because, forsooth, the Company confidently expected, backed up by Smith and Co., that the Government would buy the works out and out with all their defects and at a price far beyond their worth. The result, as the Water Examiner naively shows, of the project, which received his sanction some two years ago, that is the making of new pumping works at Hampton, "should have been carried out on the assumption that no such acquisition would be made, and thus the short supply would not have occurred." The Company receives a very mild rebuke, if it can be so called, for so serious a dereliction of duty, whilst the ill-used and cheated water consumers are bid to take consolation from the fact that "by the end of the year the new engines will be at work." The magistrate before whom a complaint was made by Messrs. Jay, of Regent Street, however, refused to see the matter in the same *couleur de rose* fashion, and therefore inflicted a fine of £10 upon the Company.

With a desire to stint the consumption of water and a general disregard as to the quality of the water, the public health is very likely to suffer. This is not all, for with the re-valuation of the assessment of the metropolis the water companies, taking advantage of the circumstance, are seriously increasing the price of water. They hope in this way, no doubt, to keep up the fictitious price the water companies' shares went up to a year ago, and this will enable them to drive a harder bargain with the Government or Water Trust to be created by the next Parliament.

An eminent statesman, who had an unusually large experience of human nature, once said "that every man has his price." The water companies have probably arrived at the same conclusion, otherwise it would hardly be possible for them to find good easy-going people ready and willing to make black appear white in any emergency. It must have very much surprised those who have studied the water question in all its bearings, and thoroughly satisfied themselves as to the quality of Thames water, to find paragraph after paragraph going the rounds of the lay press to the effect that there is no purer water to be found. We are assured that "the Thames in its flow of 130 miles as a definite stream does not acquire any increased proportion of organic matter;" and, "when examined in large bulk with the *naked eyes* (be it observed) not a trace of suspended organic matter can be seen." A most incredible assertion, as everyone who is acquainted with the facts must know. Throughout the whole course of the river; separated by only a few yards anyone may see the sewage refuse of hundreds of thousands of human beings living on its banks, or floating on its surface, flowing into and percolating through the soil into the stream. It has long been held to be a public scandal that the inhabitants of considerable sized towns should be drained into the Thames, and above the intake of the water companies. It is now Moulsey, then Henley-on-Thames, that is appealing to the Local Government Board for assistance to stop its drainage into the Thames. Can anyone be insane enough to believe that any filtration of the water companies will strain the sewage out of water so contaminated? And it can be incontestably shown that a flow of a hundred yards must be quite an exceptional circumstance.

It is utterly misleading, then, to put forth a statement of the kind quoted. Furthermore, it is a fact that when the Lambeth Water Company were pumping from a sub-soil source at Moulsey a considerable portion of its water supply, and at the same time keeping down nine hundred cesspools to low water mark, two eminent chemists certified that "the water was pure and wholesome"—a parody on the impotence of chemical analysis of water. We may ask, then, is it because of the important assistance given by chemical analysts in the discovery of bacteria in water and of "disease germs in air, that chemistry *per se* will persist in dogmatically asserting that the sewage-contaminated waters of the Thames and Lea are pure and wholesome?" We may state, and without fear of contradiction, that but for the microscope in the hands of the physician and physicist these minute bodies would have remained unknown and the specific action in disease undiscovered. Is it likely that chemistry would have made the discovery of "the attenuated anthracoid microbe" of Pasteur? Certainly not. These are matters quite beyond and out of reach of analytical chemistry.

THE USE OF ELECTRICITY IN THE THERAPEUTICS OF THE ANCIENTS.

Now, when all attention is directed to the opening of the Exhibition of Electricity, our readers will peruse with interest the following paper of Dr. Morand, which appears in the *Union Medicale* :—

The therapeutic use of electricity is of much greater antiquity than is generally known, for it goes back to the time of the ancients. The Greeks, the Etruscans, and after them the Romans, studied with an eagerness more prompted by superstitious belief than by a regard for science, the

phenomena of atmospheric electricity; and they recognised results not only mechanical and physical, but also physiological. They observed also with much surprise the accumulations of electricity which show themselves from time to time on sea and land, and in connection with them the light and electric sparks which are sometimes spontaneously produced by mankind and animals. They also knew the attractive power exercised on light bodies by polished amber, or by tourmaline warmed between the fingers. But amongst their various theories on these phenomena the ancient philosophers have never discovered the tie which connected them and which since the close of the last century has received the name of Electricity—quite a modern title, although derived from the Greek *electron*, amber. Electric currents and their action on animal economy were unknown to the ancients for this reason: they ignored means and instruments, which we now use to produce at will statical and dynamical electricity, and electromagnetic phenomena. But Nature offered them a perfect electric machine, the torpedo or electric ray (*Raja Torpedo*), of which the Greek name, *marké*, and the Latin, *torpedo*, explain the numbness which this fish produces in paralysing its enemies; and the Greek and Roman doctors made use of this living electric battery. We do not know at what epoch those physicians appeared who in their writings mentioned for the first time this mode of cure, though Galen speaks of them. This celebrated Greek physician of the second century of our own era explains himself clearly in his treatise on "Simple Medicines," where the following is to be found:—"Some authors have written that the torpedo applied to the head cures cephalalgia, &c. Having thought of placing the torpedo *while alive* in contact with the head of a person suffering from cephalalgia because I thought that this animal might have a calming effect like those other remedies which *dull* our sense of feeling, I found that the statement was quite true."

These experiments are also certified by the Greek doctors of the Byzantine epoch, Ætius and Paul of Egina. But already, under the Emperor Claudius, the Roman physician, Scribonius Largus, wrote in the time of Jesus Christ the following lines:—"Against any kind of gout in the feet it is necessary when the pain begins to place under the feet of a patient on a shore, not dry, but *washed by the sea*, a black *living* torpedo, which is kept there until a numbness is felt in the entire foot and tibia up to the knee. This will relieve the pain for the present and cure the disease for the future."

Thus Scribonius Largus, a century before Galen knew that the torpedo ought to be used *while alive*, and that the *presence of water* was useful; but he did *not* know that bodies of this species were good conductors of electricity. In a word, the ancients used electricity as a therapeutic agent without being aware of it.

These details, almost unknown, were published by Dr. Morand in 1876, in the *Journal of Electricity*, which has only reached a few numbers. This journal had been started in the expectation of an exhibition like that of today, which ought to have taken place in 1877, but was abandoned on the announcement of the Universal Exhibition of 1878.

THE examinations in Sanitary Science by the University of Cambridge, open to all whose names are on the Medical Register of the United Kingdom, will begin on October 4. The names of candidates must be sent to Professor Liveing, Cambridge, on or before the 28th inst.

BOOKS AND READING FOR STUDENTS.

THE assistance medical students can hope to obtain while at work preparing for the ordeal of examination is of two kinds—that, viz., derived from oral instruction, and that obtained from books. These latter are a very necessary item in his education, and on the wisdom displayed in their selection much of his future success or discomfiture must be dependant. In all cases, therefore, consultation on the subject with an experienced teacher is advisable, for, from the number and variety of the treatises on every subject connected with medicine, it requires a tolerably intimate acquaintance with their peculiarities to determine which of so many can be most advantageously selected for the use of particular individuals. As the character of readers varies much, so do the works written for them; and it is a matter of some importance occasionally, to select the right book. The novice cannot do this successfully; hence do we advise appeal to a teacher for advice and aid. Many a man, notwithstanding, will do well for himself by inspecting more than one of the works on a subject, even though his attention is restricted to particular titles; but there are a certain number of standard text-books and helps that contain much the same material in the same way, and a list of these we feel will be often found useful to puzzled students. We give, it, therefore, as a means of helping them to find what they require, but with the advice to obtain, whenever possible, suggestions as to their reading from the teachers under whom they are working.

Anatomy.—The well-known Dublin Dissector is a good and useful guide, while, Holden's, Ellis's, Heath's, and Gray's volumes are much employed in different hospitals, Holden's, perhaps, bearing off the palm. An entirely original work, entitled "Schematic Anatomy," by Dr. W. P. Mears (Baillière), is in the press, and from an advance copy submitted to us, we judge most favourably of it. Quain's two volumes will long retain their place as the most exhaustive treatise for advanced students, while Professor Darling's "Essentials of Anatomy," and the "Pocket Gray" are useful for condensing previously acquired knowledge. Anatomical plates are prepared by Mr. Ellis, by Mr. Godlee, Mr. Hensman, &c., and the invaluable superposed atlases of Witkowski (Baillière) are rapidly gaining general appreciation.

Physiology.—Foster's "Text Book," 3rd edition (Macmillan), is the most scientific and complete of all manuals for the English reader. Carpenter's "Human Physiology," Flint's, Hermann's, and Kuss's, are extensive volumes, and all serviceable, while Kirkes' manual is much read by men who want to "get through as easily as possible." Huxley's "Elementary Lessons" is what its name indicates, and Lowne's "Aids" are a brief epitome of the outlines of physiological science. For practical work the most useful book is Harris and Power, or Foster and Langley, while the large two-volume "Handbook for the Physiological Laboratory" may be employed for reference.

Chemistry.—Roscoe, Fownes, Wurtz (Lippincott and Co.), Williamson, Semple's "Aids;" and for physiological chemistry, Dr. Ralfe's small handbook, and Dr. Gamgee's large work (Vol. I. only out as yet) are the best.

Botany.—The small amount of actual botany, apart from the names of herbs, demanded from the medical student, can be gained from Oliver's Elementary Lessons, Semple's Aids, or in a more strictly scientific fashion, from Prantl's work (a *resumé* of Sachs', and translated by Vines). For medicinal plants the beautiful atlas of Bentley and Trimen, published by Messrs. Churchill, may be consulted with advantage. Balfour's and Bentley's used to be favourite handbooks.

Comparative Anatomy.—Nicholson's or Huxley's manual, Rolleston's "Forms of Animal Life," and Rymer Jones' "Animal Kingdom" are all reliable and

valuable. Smaller works are Dr. Ord's, or Mr. Bradley's volumes, and Prof. Nicholson's "Text Book" Special works may be consulted, as Flower's "Osteology of the Mammalia," and Huxley and Martin's "Practical Biology."

Medicine.—The "Medical Diagnosis" and "Medical Treatment" of Dr. Fenwick, and "Medical Case Taking," of Dr. Warner are all indispensable; Charteris and Carter's Guides are also very useful; and for ampler treatises, Flint's "Principles and Practice of Medicine" cannot be improved on for students' use. Bristowe's, Niemeyer's, and Roberts' are all standard works, and the "Aids to Diagnosis," Parts 1, 2, and 3, by Dra. Fothergill and Thorowgood, contain much that the student cannot afford to leave unread. Special volumes, like Fothergill on the Heart, the same author on Indigestion and Biliouness, Wilks, Jackson, Charcot, &c., on Nervous Diseases, Dickinson, Beale, Johnson, &c., on the Kidney, exist in great number, and ought to be frequently referred to; while such systematic treatises as Reynolds' "System," Aitken's "Principles," &c., will frequently yield rich stores of information on particular subjects. In clinical medicine the number of works is legion, and we can only mention a few authors, such as Jackson, Allbutt, Gowers, Fenwick, Legge, &c.

Surgery.—Erichsen's and Bryant's are both well known to older students and those of a past generation, while Gant's "Science and Practice" is deservedly growing into favour with the present generation. Mr. Holmes single volume is a valuable work; and on operative surgery we have a large number of manuals, the chief being Bell's, Bellamy's (Surgical Anatomy), Heath's, Mears'. Mr. Spence, Dr. Pirrie, and Mr. Syme also contribute valuable treatises on practical surgery.

Pathology.—Billroth's volumes are invaluable; Wilks and Moxon's work is somewhat old, but nevertheless cannot be too highly praised. Dr. Green's little handbook is that most generally read by students, and for further details of an exhaustive kind, Rokitanaky, Cornil and Ranvier, and Rindfleisch are available.

Midwifery.—Playfair, Barnes, Leishman, Lloyd Roberts, are all standard works. Mr. Burton's "Midwifery for Midwives" is a valuable little volume (translated from the German); and Swayne's "Aphorisms" will long remain a favourite condensed guide to obstetrics.

In **Gynecology**, Dr. West's "Diseases of Women," edited by Dr. Duncan, and the latter's lectures, are excellent, while nothing too commendatory can be said of Dr. Thomas's highly popular work on the same subject. Among smaller treatises we can mention as worthy of confidence Dr. Lombe Athhill's and Dr. Galabin's little works.

Materia Medica and Therapeutics.—Ringer's, Garrod's, Semple's "Aids," Scoresby Jackson, Davidson, Naphey's, &c.

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

THE CONNECTION BETWEEN NORMAL MENSTRUATION AND MEMBRANOUS DYSMENORRHOEA.—At the last meeting of the Académie de Médecine M. de Sinéty read a paper on the "Connection that existed between Normal Menstruation and Membranous Dysmenorrhœa." From observations that he collected, he found that in the physiological state the mucous membrane of the uterus is not eliminated under the influence of menstruation contrary to what he had believed himself, and to what was generally thought. However, in certain pathological conditions, the mucous of the body of the uterus exfoliates and is expelled at the catamenial period. This phenomenon, to which the name of membranous dysmenorrhœa is applied, is frequently accompanied

by great pain and a more than usual loss of blood. It does not constitute a special disease. It is observed in very variable conditions with or without metritis. The exfoliation in these cases results from an exaggeration in the normal menstrual function, causing a too intense infiltration of the deep layers of the mucous membrane and a compression of the vessels of this region, from whence elimination of the superficial tissue. Thus it can be seen that whatever impedes or delays the current of blood through the superficial vascular system of the mucous membrane can be a cause of membranous dysmenorrhœa. A histological examination of the pieces expelled is necessary to establish a diagnosis, and consequently to adopt a rational treatment.

THE INOCULATION OF CONTAGIOUS PLEURO-PNEUMONIA.—M. Bouley read a report he had made on the "Inoculation of Contagious Pleuro-Pneumonia." Inoculation of the virus made in the tail of the animal preserved it from this redoubtable disease, whilst the same operation practised in the regions richest in cellular tissue caused death. Sixteen cows were inoculated in the flap under the throat; the results were disastrous. On the other hand, all the animals that had been inoculated in the flap after having been inoculated in the tail with the same virus, remained intact. Since these inoculations were practised at Hastelt, in Holland, the ravages of pleuro-pneumonia had greatly diminished. M. Bouley concluded his communication by expressing the hope that they would succeed in attenuating one day the virus of pleuro-pneumonia as M. Pasteur had done for the cholera of fowls and M. Toussaint for the charbon.

INTESTINAL OBSTRUCTION.—At the Societe Medicale M. Bonnefin related an interesting case of intestinal obstruction in a man, aged 72. His father who lives still has attained the patriarchal age of 102. This man had a retention of fecal matter which lasted fifteen days. Enemas and purgatives had no effect. The patient had fever and frequent hiccough, nausea, and vomiting, but not stercoral. The abdomen was tympanitic hard in the right side, especially in the region of the cæcum, where hardened matter was felt, the left was free, which was owing to the frequent forced injections. The pulse was small and perspiration abundant. M. Bonnefin treated him by electricity, the first operation remained without result, nor was it until the fourth, which was practised ten days afterwards, that an abundant discharge could be had. The man recovered without any bad symptoms.

CREOSOTE IN PHTHISIS.—Dr. Reusse before the same Society was asked to give his opinion on the treatment of "Phtthisis by Creosote." For the last twelve months he had treated a number of patients with this agent and 73 per cent. were benefited by it, he did not hesitate to attribute this success to the exclusive use he made of creosote associated with balsam of Tolu, leaving aside the creosoted cod-liver oil or creosoted glycerine, which he found was not often absorbed. Balsam of Tolu combines very well with creosote, it is an energetic stimulant and facilitates expectoration, thus aiding the creosote in exhausting the source of the expectoration. M. Reusse gives the creosote in the form of lozenges containing four grains or drops of Tolu balsam and one of creosote. Four or six of these pastilles to be taken daily. Under the influence of this treatment the strength and the appetite return, consumption stops, the weight increases and auscultation reveals the arrest and amelioration of the disease.

TREATMENT OF FISSURES OF THE ANUS.—The *France Medicale* says that fissures of the anus are radically cured eight times out of ten after three weeks of the following treatment: Every day an enema of warm water with a tablespoonful of glycerine. After each evacuation introduce into the anus a plug of lint about the size of the little finger, coated with the following pomade, glycerine, one ounce; olive oil four drachms; exonge, an ounce and a half. Some of the same pomade should be put around the external orifice of the anus. It is often observed that patients who suffer from purulent endometritis with, or without, ulceration of the os, are unable to support balsamic injections, such as coal tar, which by their nature are more apt to dry up the source of this morbid secretion. In these cases the employment of a solution of tannic acid in glycerine with a certain quantity of laudanum has produced the best effects. Two ounces of tannic acid are dissolved in ten ounces of pure glycerine by heat. Of this solution an ounce in warm water to be used in injection morning and evening. The

purulent secretion diminishes rapidly, irritation of the external parts disappear, and the sensation of weight and pain is considerably abated.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, SEPTEMBER 28, 1881.

THE CASE OF PRESIDENT GARFIELD.

By means of telegrams to the daily papers the profession in this country, as well as the public generally, has had full details as to the symptoms which characterised the case of General Garfield from the time—now upwards of eleven weeks ago—when he received his wound until his much lamented death. Since that event took place the course of the fatal bullet has been traced; the precise injuries inflicted by the missile noted; and the circumstance by no means uncommon in cases of gunshot wounds penetrating the abdomen observed, that in regard to both those points opinion formed during the life of the illustrious patient had been somewhat astray.

The more important phases of the case are summarised thus:—On July 2nd the wound received. Severe shock followed, with symptoms of internal hæmorrhage. After an interval the patient rallied, then suffered from severe pain along the right leg and foot—assigned to pressure on, or injury of, one of the lumbar nerves. In due time traumatic fever set in, characterised by its usual symptoms. On the 23rd rigors occurred. A counter opening made in the loin gave exit to a considerable quantity of pus. From

that date the symptoms of traumatic fever persisted and increased in severity. On 8th of August a second counter opening was made. Now there are evidences for the first time in the bulletins of strength beginning to fail. Gastric irritability to a great extent was also present. On the 14th ult. nourishment had to be administered per rectum. On 24th a parotid abscess, which for some days previous had been forming, was opened. A few days later a second abscess in the same region was opened. On the 6th of September the patient was removed to Longbranch. The journey was, upon the whole, well borne; but from this date congestion of the lungs set in, and the general train of symptoms became aggravated. On the 17th a rigor occurred. On the 19th he had two rigors. Later in that day he was seized with severe præcordial pain; he became almost immediately unconscious, and died.

Briefly, the state of things revealed by post-mortem examination was this: the bullet had fractured the right eleventh rib, passed through the body of the first lumbar vertebra in front of the spinal canal, driving some small fragments of bone into the soft parts in its course, and finally lodged below the pancreas about two inches and a-half to the left of the spine, and behind the peritoneum, where it had become encysted. Death had occurred, not from the formation of a clot in the heart, as at first suspected, but by secondary hæmorrhage from one of the mesenteric arteries adjoining the track of the bullet; there was an abscess of large size in the vicinity of the gall-bladder, between the liver and transverse colon, both of which were adherent; a suppurating canal extended from the internal wound between the lumbar muscles and right kidney, nearly so far as the right groin; evidences of bronchitis and broncho-pneumonia were found, and on the left kidney there was a small abscess. Comparing the facts discovered by necropsy with the telegrams published while the illustrious patient yet lived, the following points present themselves: The bullet was found, not only higher up than the point to which it was believed to have penetrated, but on the opposite side of the body: an accumulation of pus in the muscles of the loin appears to have been all along mistaken for the bullet itself; yet the fact is rendered evident that from the moment the shot was received by the President his death by it was to all intents and purposes a certainty,—that the injury was beyond the scope of surgical art. That the powers of life only gave way on the 19th September, namely, seventy-eight days after the receipt of the wound, only proves how great was the original strength, as well as moral pluck of the patient. As the vaunted aid said to be given by a so-called instrument of precision in diagnosing the position of the bullet, the whole thing is shown to be a fallacy.

According to more recent telegrams, the autopsy is likely to give rise to an unpleasant controversy. This circumstance is greatly to be deplored. Unseemly, as altercations are over the sick bed, they are still more so a hundredfold over the closed-in grave. It is well-known, however, to military surgeons accustomed to treat such injuries as that of General Garfield that frequently it becomes impossible to trace, with anything approaching precision, the course of a bullet penetrating deeply.

While the medical profession generally in America

approve of the line of treatment followed, the non-professional public are said to be lost in wonder at what they consider to have been a misconception by the attending surgeons as to the actual nature of the wound. It is, moreover, thought that undue reticence was at times maintained by them in their daily bulletins. With regard to these and other matters connected with this very sad case, our further remarks are reserved pending the fuller reports, which, no doubt, we shall receive in due time.

THE INTRODUCTORIES.

THE season of the "Introductories" is fast approaching, and ere this week is passed a certain number of well-worn platitudes will have been addressed to audiences composed for the most part of aspiring new students and their admiring friends, all of whom are prepared to join in the pleasing and satisfactory task of prophesying smooth things, while conveniently neglecting the rough.

Other philosophers having tried and failed to find sufficient excuse for the ceremonial observance of opening days after the manner usually pursued in regard to them, we do not feel called upon to offer any explanation of it. We may, however, unite with those who fail to see the dignity or advantage conferred, either on the profession of medicine or of the particular centre he illuminates, by a long-winded oration on nothing by this or the other teacher or official. As a means of bringing together those who are about to be associated in a common pursuit, social gatherings preliminary to the active work of the session may be productive of good; but to be so they must be of a less formal kind than the solemn assemblies at which introductory are delivered. Those who do happen to know each other, here meet somewhat as doomed criminals might meet before execution, with a dismal dread of some grave ordeal immediately before them; while as for any hope of introduction between the unacquainted, or easy chat such as leads to the growth of friendly feelings, as much chance of securing them would be found in church on a Saint's day. The audience is there for a purpose, and that purpose is to hear the "Introductory Address." When its purpose is accomplished, the first aim is swift and perfect relief by escaping from the scene of the oration, and in a moment the whole meeting is scattered into fast disappearing units and small groups. Under such circumstances—and they are familiar to us all—there is no opportunity afforded for that which it is the aim of the "Introductory" in part, at least, to accomplish, viz., mutual introduction. This has, therefore, to be gradually achieved by a slower and sterner method; and thus is one of the chief benefits that might be gained at the outset of student life utterly and completely lost.

On the other hand the "Introductory" fails even to do that which is indicated by its title. It ought to be directive of the future course of the young, untried, inexperienced student. It should unfold to him the lines on which his efforts should proceed, and by depicting the prospect before him, encourage and equip him for the struggle he has engaged in. How often, however, is this accomplished? How many introductory addresses has any reader of this paper "sat out," from which it was possible for any student attending to it to carry away one

suggestion of practical value in his life as a student. The magnitude of the physician's labours is a brave, is an admirable, subject to dilate upon; but the young heart, bursting with ambition to secure the first fruits of practice, needs none of the orator's eloquent promptings at this early stage of its career. Nor does it require to be damped in ardour by being told of the difficulties that must be encountered. If it does not appreciate, it, at any rate, despises them, and nothing uttered from human lips, be they never so authoritative, will convince the hearer of the unreality of his dreams. Indeed, from whatever standpoint we may regard the introductory address, it must seem a barren and a profitless labour, and we trust the time may not be far distant when more rational and more productive ways of declaring the medical year has commenced at each particular school, may be devised.

It is to be feared, however, that the practice accords too well with the *laudator temporis acti* spirit that dictates it, and that many men will yet be found to endorse the ancient custom. Feeling this, and feeling, too, that even by a little, improvement may be made in the mode and matter of delivery of the introductory, we have ventured to put together a few notes, which are hereby placed at the service of all and each speaker introductory of the approaching session. We do not pretend that these brief memoranda will cover every orator's ground, but we do know that, judging from past experiences alone, the heads indicated below will accurately include at least ninety per cent. of the addresses to be delivered before next Wednesday. Conscious of the labour involved in the work of preparation on the part of the about to be delivered orators, and anxious to spare them as much of grinding pains as possible, we present these notes for the good of all, only omitting points bearing on the special schools addressed, which must of course be inserted by each for himself. In other respects these notes are in rough outline the speeches for which in full our contemporaries must be consulted at a later date.

"Regret it has fallen to my lot—flattering duty imposed—importance of *our* school—the eyes of the country turned upon it—posterity—its fame will throw into shade the Blacks, Cullens, and Monroes of a certain northern establishment. Not for us to blazon forth our own praise—yet take credit on behalf of learned colleagues—not perhaps a more able school in Europe. Advantage of having everything taught under the same roof—concentrate the pupils—dotage of Oxford and Cambridge—disadvantages of those places—subscriptions expense—folly of Greek, or of more Latin than the Apothecaries' require—our mode of managing matters—economy—enlightened spirit of the age.

"Changes which we have in contemplation. Major verum nascitur ordo—*Majus opus*. External distinctions—gowns and caps—with bells or not?—prizes for some, titles for all—difficulty of finding denominations not already engrossed (a proof of the corruption and monopoly of the old universities)—propose *magnus* in midwifery, *major* in surgery, *maximus* in medicine—or altogether generals in practice—not general practitioners—probable value of our diploma—highly honourable at all events.

"Plan for studying universal disease in the whole of animated nature—human pathology illustrated by comparative—proposal to establish a general hospital properly so called—separate apartments for different classes of animals—but all united. Unity in all things—only money wanted—free to pupils—shame of making those pay who are only learning. Reformed Parliament. *Mem.* Discount to those who attend all, and money returned to those rejected.

Our museum—just a few things—but shall not have time to day—osteology—splendid drawings—unique preparations—superb wax works. *Mem.* Must have them all out.

Few words on medical science—France and Germany—loss of Cuvier—a year big with the fate of great men—allusion to death of X. Y. Z.—Shakspeare a great physiologist—knowledge of human nature—what a piece of work is man! &c.

Generous emulation of pupils—genius without industry *flocci nauci*—anecdote of John Hunter—motives from self-ambition.

Knowledge is power—Lord Bacon, Solomon—credit of the school—fame ultimately on pupils—conduct most exemplary—never the least riot or disturbance—morality above all things—the great end and aim—value set on character as a gentleman. Myself—promise nothing—past life and services—professional works—the press—press of business, &c.

RE-ORGANISATION OF THE SANITARY SUPERVISION OF DUBLIN.

THE death, some months since, of Mr. Boyle, the Secretary of the Public Health Committee of the Dublin Corporation, has afforded that body an opportunity of re-organising its sanitary department. Mr. Boyle's handsome salary had lapsed, and the greater part of it might be saved, or else distributed in the way of increase of salary to those already in office. But the Corporation has recently got permission to increase its debt, and to add to the taxation of the citizens who already pay toll to the extent of 9s. 8d. in the pound of their house valuation, and it has availed itself of its new powers of saddling the citizens with an additional £1,000 a year for the Lord Mayor. Naturally, the civic fathers of Dublin were not disposed to be parsimonious, so they have enlarged the salary of the superintendent medical officer of health from £450 to £1,000 a year, given him the additional appointment of executive sanitary officer, hitherto held by Mr. Boyle, and provided him with an assistant at £200 a year to perform the work heretofore devolving upon the deceased gentleman.

To say that this transaction is an unqualified job, is equivalent to repeating that it is the act of the Dublin Corporation, which body has never yet been known to make an appointment from that of Lord Mayor, or down to that of civic charwoman upon any other principle than that of providing comfortably for a friend, a *protegé*, or a brother politician, out of the pockets of the taxpayers.

We do not, in the least, grudge the chief medical officer of health for Dublin his £1,000 a year. On the contrary, we think that salary altogether insufficient for the due per-

formance of the duties of the office by a gentleman of Dr. Cameron's attainments and energies. But, as it is physically impossible that that gentleman can give "due performance of the duties" in return for his salary, as long as he retains his multitudinous pluralities, we protest against the health of the citizens being trifled with by the perpetuation of an arrangement which has covered the Public Health Committee and the Corporation with such well-merited disgrace.

The Royal Commission on Dublin Sanitation have pronounced officially the opinion which everyone holds and which the conjoint report of the Colleges of Physicians and Surgeons has re-echoed, *i.e.*, that the sanitary administration of Dublin would be barely provided for by the close and exclusive attention of the chief medical officer, and that the attempt to work the department as one iron in the fire along with a dozen others is all wrong. We are told by the corporate advocates of this new job that the medical officer of health is to give his whole time to the civic duties *except* that which he is obliged to expend on his work as public analyst for the city, *except* the period of his lecturing as professor of chemistry in a medical school, *except* the time spent on his work as chemist to thirty-five counties in Ireland, and as private analyst to everyone who asks his advice. We say advisedly that with such a load of labour as this upon him no individual can possibly do anything like justice to the public health of a city renowned for its filth, saturated with insanitation, and laden with a population of over a quarter of a million of persons—mostly dirty and ignorant. We therefore hope (though, knowing the somnolency of the Local Government Board, we don't expect) that this chance will be seized by the authority which is supremely responsible for the sanitation of Ireland to insist on proper provision being made for the supervision of the health department of the city.

We should applaud the appointment if Dr. Cameron were paid a sufficient salary and required to do the work and nothing else, but we cannot but protest against a job which costs a large sum and can produce no substantial return to the citizens in the way of improved sanitation.

THE NOTIFICATION OF INFECTIOUS DISEASES.

THIS much-disputed question is likely to be the focus of animated debate in the Public Health Section of the approaching Social Science Congress in Dublin, and we urge upon the attention of the medical profession the necessity, not only in their own, but in the public interest, of making their opinions heard and their influence felt on the occasion.

It is vitally important that the medical aspect of the subject should be fully set forth, because there is no doubt that the verdict of this meeting will, if favourable, be used in the next session of Parliament to promote the Bill to make this Notification compulsory on the physician. Such a Bill was introduced in the last days of last session to the House of Commons by Mr. Hastings, M.P., acting on behalf of the Social Science Association, and it would certainly have got a second reading but for the opposition of Mr. Thomassen, the member for Bolton, who "blocked" it and refused to be charmed into withdrawal of his oppo-

sition. This same Bill will again make its appearance in February, and, if the promoters are able to say that it was accepted and approved by the Congress in Dublin, they will have a potent argument in its favour. We, therefore, earnestly urge the members of the profession in Dublin to make it their business to be present at the forthcoming meeting, and to record their firm determination not to be made the tools of gushing sanitarians.

The Bill in question goes the whole length with these theorists, for it puts the physician under penalty of prosecution and a fine of £5 if he does not furnish a written report of each case to the sanitary authority; and although for the present Ireland is exempted from its operation by a special clause there can be little doubt that a strong effort would be made to bring that division of the kingdom within its grasp by moving the omission of the exemption clause, a proposal which it would be almost impossible to resist in the House.

We, furthermore, warn the profession that they need not hope for any serious defence of their position by the British Medical Association. The Parliamentary Bills Committee of that Association is in the hands of the Chairman, who is a violent notificationist, and who subscribes to the doctrine fashionable with the advocates of the measure that the physician should be content to be sacrificed for a supposed public gain, and, accordingly, the opposition of the Committee has been hitherto half-hearted and insignificant. We are well aware that the rank and file of the profession in England entertain, just as strongly as their brethren in Ireland, the objection to be made the public detective of their patients' ailments; but nine-tenths of them are in complete ignorance of the nature of the proposed measure, and the official organ of the Association studiously abstains from educating them on the subject. This is not as it should be. A great danger threatens the independence of the profession and its dearest interests, and the British Medical Association ought to be the first to raise the standard in defence. It hangs back; but we are confident that the physicians of Ireland will not do so. If they are firm in their determination, and if they give themselves the trouble of making their opinions heard, they have already defeated the onslaught. If they shilly-shally about this matter they will without doubt be made the enforced servants of the Dublin Corporation and the whole genus of sanitary authorities.

It is obvious that those whose trade is sanitation have very little appreciation of the position of medical men on this matter. Here is the public pronouncement of one of them at the late meeting of the British Medical Association:—

"He could not see any reason why the medical man should not notify to the sanitary authority. It had been said that it was an interference with the private and confidential relationship between the medical man and his patient; but if the safety of the public depended upon making known the existence in the patient's house of an infection, *the medical man had nothing to do with the question of confidence in regard to that matter.*"

It is necessary to teach these gentlemen that physicians are something more than sanitary machines and civic process-servers, and we hope that that lesson will be given at the coming meeting of the Social Science Congress.

Notes on Current Topics.

The Vaccination Question.

MR. P. A. TAYLOR, has written and printed for circulation what he has entitled "Current Fallacies about Vaccination," and which assumes the form of an epistolary rebuke to Dr. Carpenter for his recent references to anti-vaccination in the essay on "The Morality of the Medical Profession." The nature of Mr. Taylor's reasoning may be at once judged from the title he has given to his address, but the present pamphlet is probably more remarkable than those hitherto proceeding from the same pen, for the self-destroying logic it embodies; a strong point is always made by anti-vaccinationists of the possible dangers associated with the use of impure lymph, and frequently before they have fallen into the strangest error from employment of the weapon they conceive this argument to be. Mr. Taylor, however, has specially excelled hereupon by the method of "proving too much." Thus, on page 28, of his pamphlet, he quotes Mr. Brudenell Carter—charitably surmising to Dr. Carpenter "Of course you have heard his name"—to the effect that "a large proportion of the cases of apparently inherited syphilis are in reality vaccinal, and that the syphilis in these cases does not show itself until the age of from 8 to 10 years." This is, of course, a crushing blow to deliver against vaccination, but, unfortunately, for the force it is likely to exert, Mr. Taylor has quoted also on page 29, a further declaration, this time from Dr. Farr's appendix to the thirty-seventh Annual Report of the Registrar General, that, "of nearly 2,000 deaths ascribed to syphilis (in 1874) 1,484 were babies under 1 year of age." The conclusion to be drawn from the passages we have italicised in these two expressions of opinion, needs no enforcing, but it will no doubt serve to exercise the inventive powers of Mr. Taylor and his followers to find an explanation of the discrepancy in accordance with the particular religion they represent. The bitter opposition set up against animal vaccination is further urged in this remarkable letter, which, throughout, is distinguished by the powerful obstinacy and perversion so strikingly exhibited by anti-vaccinating sentimentalists. In pursuing the contest with these misguided zealots it is a great misfortune that scientific reasoning and the meaning of facts are misunderstood by them; that they are blinded to the perception of any data not bearing in the direction to which they are constantly turning; and that sheer ignorance of fundamental truths and natural laws, as they relate to diseases when presented to them do but serve to mislead them yet further and further astray. We honestly regret that Mr. Taylor, or any other intelligent man, should be prevented from grasping the real meaning of facts and figures in connection with small-pox, and from applying to them also the modifying circumstances that arise to cause apparent contradiction of results. The unwisdom of any public discussion of the question has long ago been abundantly testified, another pity is that such frequent incitement to renew a profitless argument should be possible. Anti-vaccinists may be, indeed, they often undoubtedly are, sincere in their protestations, but that they are encouraged in them by the pro-

ceedings of prominent members of the community, there can be no doubt. The pity, as we say, is in this connection. We have received, also, an anti-vaccinating production, from the pen of Mr. Charles T. Pearce, Member of the Royal College of Surgeons, England; it is a "reply" to Dr. Buchanan's memorandum on the prevalence of small-pox in London, and differs from most of the compilations of a similar kind in that, it is, perhaps, a trifle more violent in tone, and is written by a duly qualified medical man.

Legal Starvation.

DURING the past week several cases have been reported in the daily papers that illustrate very forcibly the faulty condition of our poor-law administration. In one instance details of a peculiarly painful kind are forthcoming to show that radical changes are urgently demanded in the regulations under which relief is afforded to starving paupers. This was the case of a young child, for whom the person in charge of it was unable to procure a sufficiency of food; and who, therefore, made application to the parish for assistance on its behalf. This having been refused by the relieving officer, the parish doctor next saw the unfortunate infant; and in spite of his urgent declaration that it was dying for want of nourishment, the custodian of the parochial loaves persisted in his refusal to grant it a supply of food. Death naturally ensued, and post-mortem examination unmistakably showed that starvation had been the cause of it. A correspondent, writing to a contemporary, draws attention to the fact that a parish doctor cannot order, he can only recommend, nourishment for any one of his patients; and this points to a measure of reform that is most pressingly needed. The number of cases of starvation that a medical man can immediately testify are, unfortunately, too numerous to admit of any doubts concerning them; and it would seem no more than simple humanity to leave the power of ordering the necessities of existence in the hands of a trained official, instead of reposing it altogether in those who, as in the case mentioned above, too frequently show themselves utterly callous to all human suffering. We trust the exposure so unhappily brought about will have the effect of securing the essential improvement of what is, in its present form, a most injurious provision of the law.

The Clerical Abduction Case.

THERE is very much of a suggestive nature to a reflective mind in the facilities that were commanded by the abductors of a clergyman on the eve of his marriage last week. At one time it would have excited little surprise, perhaps, that such an occurrence could take place almost in open day, and certainly in the most crowded part of London. It revives the stories, almost mythical, of persons spirited away to unknown spots without the intervention of any helping hand, the explanation of insanity being all sufficient to account for whatever violence was exhibited. There is, however, the assurance always to hand that any permanent detention in a duly-licensed asylum of such an improperly arrested individual, even though his captors succeed in getting him so far confined on a plea of mental unsoundness, is wholly im-

possible, since the Commissioners in Lunacy would, in such a case, speedily bring about his liberation. Reform, however, we cannot but think, as we have indeed often urged, is required to re-arrange the system under which removal and certification are carried out; but no fear need now be entertained in respect to improper detention after these preliminaries are accomplished.

Indian Medical Items.

THE two main features of the death registration for the past year in India are—a great degree of cholera prevalence, and a considerable increase of fever mortality. The cholera deaths registered throughout the Bengal Presidency in 1880 were 39,043, as against 136,363 in 1879. Fever prevailed with great severity in some parts of Central Bengal. The heavy rain in October is believed to have been the cause. In the district of Nuddeah fever deaths amounted to 25,035, against 7,014 in 1879.

The British troops at Kurrachee are said to have suffered lately from sickness to a very unusual degree, but of less than 500 men about 100 were said to be on the sick list. The cases were for the most part of fever or scurvy; the latter especially prevalent, and reported as increasing. It is stated that the barracks at present occupied are considered to be objectionable as to site, and that the erection of new ones at Gizai, facing the sea, has been recommended.

Cholera is reported to have been recently very prevalent at Lahore. Orders were issued for the removal into camp of the British troops and their families. At Jullundhur the disease was also very prevalent.

Bromide of Ammonium in Whooping-Cough.

BROMIDE of ammonium vaunted in the treatment of whooping-cough by Harley, Gibb, and Ritchie, has lately been tried again at the Dresden Clinique for Diseases of Children, with the best results (*La France Medicale*). Kormann has convinced himself that from the first doses the frequency and intensity of the fits of coughing diminish. The bromide is administered as follows:—Every two hours 15 centigrammes for children under one year of age; 25 to 40 centigrammes for older children, suspended in coffee or in a draught sweetened with liquorice. The medicine should be taken after a fit of coughing to avoid its being vomited. Even very young children bear relatively large doses of the remedy. At most there is observed sometimes apathy and somnolence, which disappear in a few hours on the remedy being suspended. The existence of gastric catarrh is a contra-indication for the employment of bromide of ammonium.

Soiree at the College of Surgeons, Dublin.

ON Tuesday, October 4, by kind permission of the President and Council of the Royal College of Surgeons, the Statistical and Social Enquiry Society gives a soiree to the Social Science Association. Admission will be strictly confined to the members and associates of the Congress (on cards being produced), and to Fellows of the Royal College of Surgeons and members of the Statistical Society on signing the rolls.

The Health of Ireland.

THE death-rate in the sixteen principal town districts of Ireland for the week ending September 17th was 18.7 per 1,000. The deaths from the seven principal zymotics in the sixteen districts were equal to an annual rate of 2.6. Among the 55 deaths from all causes registered in Belfast are 6 from diarrhoea; among the 33 deaths registered in Cork are 2 from scarlatina, 2 from typhus fever, and 4 from diarrhoea; among the 15 deaths in Limerick are 1 from measles, 2 from scarlatina, 1 from typhoid fever, and 2 from diarrhoea; and among the 14 deaths in Londonderry are 3 from typhus and 1 from typhoid fever.

In the Dublin district the deaths were 147, representing an annual rate of mortality of 21.9. Twenty-one deaths from zymotics were registered, being 3 over the preceding week, but 26 under average: they comprise 1 from measles, 2 from scarlatina, 1 from diphtheria, 4 from croup, 3 from fever (1 typhus, 1 typhoid or enteric, and 1 simple continued fever), 2 from erysipelas, 7 from diarrhoea, &c. Thirty new cases of typhus (including 6 members of one family) were admitted into the hospitals, being 17 over the preceding week; 13 typhus patients were discharged during the week, 1 died, and 66 remained under treatment on Saturday last, being 16 over the number in hospital at the close of the previous week.

The mortality in twenty large English towns, including London (in which the rate was 15.5) was equal to an average annual death-rate of 17.3; in Glasgow, 20.6; and in Edinburgh, 15.9.

An Austrian Sanitary Congress

HAS recently been opened in Vienna, uniting the Austrian and German Societies for the Protection of the Public Health. The inaugural address was delivered by the Bavarian Duke Charles Theodor, who not long ago took his degree of Doctor of Medicine. He pointed out that the protection of the public health was a question that had only lately occupied attention, yet, though sanitary societies had not been in existence ten years, their efforts have been already crowned with success. The reforms advocated by them had been introduced both into public and private life, and the result was to be found in the public thoroughfares and buildings, in schools, factories, and ships—in fact, everywhere. They should not direct their endeavours to the benefit of a certain number, but to the improvement in the physical existence of the million. It was officially announced on behalf of the Government that the resolutions of the Congress would not only be carefully considered, but practically carried out. The chief subjects of the papers and discussions are epidemic diseases and their treatment; disinfection; the management of, and attendance at, funerals; water supply; school hygiene; and sanitary improvements in cemeteries.

French Medical M.P.s.

THE *Chambre des Deputés* elected in 1877 contained 37 doctors, and the new one just elected will contain 52. There are also three pharmacians in it.

Boycotting of an Irish Dispensary.

THE medical officer of the Carrigrohilly Dispensary in the Middleton Union, county Cork, was recently dismissed under sealed order by the Local Government Board for Ireland. He was a member of the local branch of the Land League. After the dismissal by sealed order a new election was ordered. The election was held, and the dismissed officer being one of the candidates, was re-elected by a large majority. The Local Government Board refused to recognise the appointment, and ordered a new election. The new election took place on September 16, and again the displaced officer was placed at the head of the poll by a large majority. The people a few nights ago broke in the dispensary house door to show their feeling of dissatisfaction at the appointment, *pro tem*, of a new officer.

Queen's University in Ireland.

EXAMINATIONS in the Faculty of Medicine commenced last Monday week, and will terminate on the 29th inst. ; and a meeting of the University to confer degrees will be held on October 13th.

Bequests and Donations to Medical Charities.

COL. DIGWEED, late of Echenswell, bequeathed £400 to the Hants County Hospital. Mr. David Mackintosh, late of Romford, bequeathed £200 to the London Hospital, £100 each to the City of London Hospital for Diseases of the Chest, the National Hospital for the Paralyzed and Epileptic, and the Eastern Counties Asylum Imbeciles and Idiots. Mr. James Marshall, formerly a merchant of Trinidad, bequeathed £500 each to the Royal Infirmary, the Eye Infirmary, and the Western Infirmary, all of Glasgow. St. Bartholomew's Hospital receives £500 under the will of the late Mr. W. N. Rudge, of Draper's Gardens. Mrs. Adam Findlater has given £200 to Sir Patrick Dun's Hospital, Dublin. Catherine Teulon, late of Bandon, has bequeathed £50 to the Hospital for Protestant Incurables, Cork.

The Naval Medical Service.

NOTWITHSTANDING the liberal terms presented in the last new Royal Warrant for medical officers in the army the results of the recent examination of candidates clearly show that they have so far been sufficient to attract more than fourteen candidates for forty vacancies in that service. We naturally inquire, How is this, seeing that in several important respects the position, pay, and prospects of naval medical officers have been materially improved by that Warrant. Already letters on the subject appear in our contemporaries ; among the deterring causes mentioned in those communications the greatest and most important appears to be the "discretionary powers" reserved to themselves by the Board of Admiralty, in regard to the entire disposal of their medical officers, the latter being to all intents and purposes left in the very undesirable position of having no rights whatever, so long as they are serving. One of the conditions most valued is the right to *claim* retirement after twenty years' continuous service in the same manner as that enjoyed by other members of the naval service. A second deterrent cause appears to be the fact that compulsory half-pay may be forced upon a medical

officer before he has completed twenty years' service. A third, in the still vexed question of cabin accommodation. There are other items adduced with regard to which candidates appear still to look shyly upon service in the royal navy ; but as the desire of the Admiralty really seems to be to act liberally towards them, we trust that in due time one after another may be removed, and service afloat restored to popularity.

Horse Sausages.

ONE of the magistrates at a London Police Court last week delivered his decision in the case which was brought before him by the sanitary authorities of Poplar, in which a manufacturer of German sausages was charged with having on his premises a quantity of horseflesh for the purpose of preparing it for human food, the same being unwholesome. The Medical Officer of Health for the northern division of the Poplar district deposed that he examined the meat, but was unable to say whether it was or was not horseflesh, while to him it appeared to be fit for food. The magistrate said that the contention whether horseflesh was or was not fit for human food he had not considered an important element in the case, but in the face of the evidence tendered it was impossible for him to put the law into motion ; summons dismissed.

A Lady Quaok.

A MEDICAL gentleman practising in the metropolis applied lately to the magistrate of the Southwark Police Court for his advice under the following circumstances. A lady, connected with the medical profession, had taken premises which she called a Ladies' Medical College ; and she had issued a prospectus in which he was announced as president, without his authority. Several other names were printed as members of the council, but, in fact, these gentlemen had never been consulted in the matter. There was no council in existence, and he and those whose names had been printed wished to repudiate any connection with the institution or its management, for which they were in no way responsible. The magistrate said the only advice he could give the applicant was to write to the Press disclaiming any connection with the institution.

The Health of Foreign Cities.

THE rates of mortality in the foreign cities do not unfortunately show such favourable bearings at the present season as in this country, for we find that whilst in London the extraordinary low death-rate of 15 per 1,000 of its population is reached, most foreign cities have double, and in some cases treble that number. The last weekly returns give the following as the ratio of deaths per 1,000 of the populations referred to :— Calcutta 25, Bombay 36, Madras 36, Paris 24, Geneva 23, Brussels 19, Amsterdam 18, Rotterdam 17, The Hague 20, Copenhagen 17, Stockholm 23, Christiania 17, St. Petersburg 41, Berlin 27, Hamburg 22, Dresden 25, Breslau 30, Munich 36, Vienna 25, Prague 23, Buda-Pesth 30, Rome 29, Turin 23, Alexandria 46, New York 29, Brooklyn 24, Philadelphia 21, Baltimore 31. In New York and Berlin diphtheria is still very prevalent ; malarial fevers in Rome, and typhus in the Indian cities.

Dr. McClintock, of Dublin.

We are gratified to learn that the alarming illness of Dr. McClintock, which we announced the week before last, is taking as favourable a course as could be expected. The aphasia is passing away and nourishment is taken in sufficient quantity and with readiness. We earnestly hope to be able to give a still more favourable report next week.

Treatment of Otorrhœa without Lesions of the Bone.

IN cases of otorrhœa without lesions of the bone, M. Brisson advocates the instillation of a few drops of the following solution about five times a day:—Hydrate of chloral, 3 parts; sulphate of alumina, 5 parts; distilled water, 100. In all the cases mentioned by the author, these instillations cured the otorrhœa, if not the deafness, in the course of a few days. This local treatment must be accompanied by general constitutional treatment in order to prevent relapses.

The Globe understands that Professor M. Pasteur has resolved to visit the Bordeaux lazaretto to study yellow fever, and ascertain whether it is due to a parasite, and can be guarded against by inoculation.

THE annual rates of mortality in the principal large towns of the United Kingdom per 1,000 of the population were—Oldham 12, Leeds 13, Wolverhampton 14, Bristol 14, Bradford 15, London 15, Edinburgh 15, Salford 15, Birmingham 16, Sheffield 16, Brighton 16, Manchester 16, Sunderland 17, Plymouth 17, Newcastle-on-Tyne 17, Norwich 18, Portsmouth 19, Nottingham 20, Leicester 26, Liverpool 28, Hull 30, Dublin 31.

FROM diseases of the zymotic class in the large towns last week, scarlet fever showed the largest proportional fatality in Hull, Nottingham, Leicester, and Sunderland; no less than 175 fatal cases of this disease have been registered in Hull since the beginning of July, of which 26 were recorded last week. The 16 deaths from diphtheria included 6 in London, 8 in Portsmouth, and 2 in Birmingham. Fever, principally enteric, showed the highest death-rate in Wolverhampton, Hull, and Newcastle-on-Tyne; 2 of the 3 deaths from "fever" in Newcastle-on-Tyne occurred in the fever hospital, and were certified as typhus. Small-pox caused 27 more deaths in London and its outer ring of suburban districts, and one in Liverpool, but not one in any of the other large towns.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

ABERDEEN UNIVERSITY. — APPROACHING RECTORIAL CONTEST.—The election of Lord Rector of the University of Aberdeen, which will take place soon after the commencement of the Session, is already affording considerable employment to a number of students. Letter writing, and speech-making, enable them to give vent to their opinions regarding the gentlemen who have been named as candidates for the office—Professor Bain and Lord Cranbrook—but it has not yet appeared that either of them has

authorised his nomination. A meeting of students opposed to Dr. Bain was held in Marischal College on the evening of the 16th inst., when a committee was appointed to select a candidate, and to thoroughly organise, what one of the speakers termed, the "Opposition Party."

THE FEVER IN DUNDEE.—The outbreak of fever in Dundee has assumed a very alarming aspect. The epidemic, which was at first confined to low lying districts in the East end, has now made its appearance in other quarters, and is rapidly spreading over the whole town. The number of cases has greatly increased within the last fortnight. From 1st to 16th September, 98 cases have been reported to the sanitary inspector, viz., typhus, 15; typhoid, 5; scarlet, 78. A considerable number of cases have terminated fatally.

DR. ANDREW CLARK ON TEMPERANCE.—Dr. Clark, whose views on alcohol are well known to our readers, is at present staying at Abbotford, but, as in these days, a "man of mark" cannot take a holiday without being morally compelled to do work of some kind, so the good people of Galashiels waited upon our *confrère* last week, with an invitation to address a meeting there on the subject of temperance. In compliance therewith Dr. Clark said that he had arrived at the position he occupied by his observations of the effects of alcohol, and he asked his hearers to be in earnest in following what they believed to be the truth. The moderate use of alcohol was not beneficial to health, nor for continuous work. At the same time, a healthy man might take a moderate quantity, physiologically considered, without injury. He admired abstainers and their work, but did not approve of their extremes, and he suggested the formation of a society which would confine its members to this physiological minimum.

HEALTH OF EDINBURGH.—Dr. Littlejohn's report states that during the week ending the 17th inst., there were 63 deaths, equivalent to an annual mortality of 15 per 1,000. This shows the health of the city to be very favourable, the number of deaths during the week being 27 below the weekly average of last year. The mortality from zymotic causes, however, has increased, no fewer than 11 deaths being due to such diseases. Of these, 9 (2 of fever, 3 of scarlatina, 1 of measles, 2 of whooping cough, and 1 of erysipelas) occurred in the Old, and 2 (whooping cough) in the New town. There were 137 births during the week, and of these 11 were illegitimate.

DEATH FROM AN OVERDOSE OF LAUDANUM.—Andrew Clark, a flax dresser, 62 years of age, lodging at 382 South York Street, Glasgow, was found dead on the 18th inst. under sad circumstances. The woman of the house, on going into his room with his breakfast, discovered him sitting on a chair quite dead. A number of small bottles, which had contained laudanum, were lying beside him, and Dr. James Chalmers is of opinion that death resulted from an overdose of this drug.

DR. JAMES STARK, OF GLASGOW.—*The Military Record and Volunteer News* of last week gives, as one of its "men of mark," a very appropriate designation for a volunteer, Dr. James Stark, of Glasgow. Along with an appreciative biographical sketch, there is an excellent portrait. We can assure our contemporary that he does not overdo his appreciation of Dr. Stark. By those who know him best, and it may be somewhat difficult to become acquainted with him, Dr. Stark is held in high esteem for his shrewdness of observation, genial humour, and detestation of sham and insincerity. We cordially join our contemporary in wishing long life to the citizen soldier whom he thus delights to honour.

Literature.

ST. BARTHOLOMEW'S HOSPITAL REPORTS. (a)

THE sixteenth volume of these Reports is in no way inferior to those which have preceded it. Several most interesting papers dealing with questions in practical medicine and practical surgery are contributed, and will be found to be valuable additions to our literature. Mr. D'Arcy Power's paper "On Ferments," "Some Cases of Abdominal Surgery," by Howard Marsh, and "Remarks on Resection of the Tendon Achilles in cases of Paralytic Talipes Calcaneus," by W. Willet, are specially worth reading.

INDEX-CATALOGUE OF THE LIBRARY OF THE SURGEON GENERAL'S OFFICE, U.S.A. (b)

THIS splendid work reflects credit, not only on the American Government, which has had the enterprise to publish it for the advance of surgery, but upon Dr. Billings, upon whom has devolved the labour and responsibility of producing it. It is *facile princeps* amongst medical catalogues, and represents an astonishing amount of literary work. This is the second volume, and it contains no less than 12,459 author-titles, representing 4,934 volumes, and 9,810 pamphlets. It also includes 11,550 subject-titles of separate books and pamphlets, and 37,310 title of articles in periodicals. It is, probably, not expected that individual members of the profession will buy such a work, but it is quite indispensable to medical libraries as a work of reference.

THE LIVERPOOL MEDICO-CHIRURGICAL JOURNAL. (c)

IT is intended that this continuation of the "Liverpool and Manchester Medical and Surgical Reports," shall contain original papers in medicine, surgery, and collateral subjects, reviews and notices of the medical literature of the day, as well as the proceedings of the Medical Institution, and reports of the meetings of the Lancashire and Cheshire Branch of the British Medical Association.

If we might venture to judge of the contents of the future issues of the journal, by the interesting and instructive matter in this, the first number, its success can scarcely be doubtful.

Correspondence.

HOMŒOPATHY AND HOMŒOPATHISTS.

Ridentem dicere verum quid vetat?
"Allopathus" me sibilat; at mihi plaudo ipse domi simul ac Nummos. Contemplant in arca."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Legal England has delusions, clerical England has delusions; why should Medical England hope to enjoy immunities which her Sisters—Law and Divinity—do not? If homœopathy died to-morrow some other "pathy" would arise from its ashes. *Populus Vult decipi et decipitur*. Messrs. Bristowe and Hutchinson missed one peculiarity of homœopaths in their recent discourses on "Consultation with them," viz., "that they can be homœopaths and allopaths by turns, according as it suits their books." (d) "Lord Beaconsfield was not treated homœopathically," says Dr. Kidd, "but in accordance with the principles applicable to

(a) "St. Bartholomew's Hospital Reports." Edited by W. S. Church and Alfred Willet. London: Smith, Elder, and Co.

(b) "Index-Catalogue of the Library of the Surgeon General's Office, U.S.A.," Authors and Subjects. Vol. II. *Berlitz* to *Cholas*. Washington: Government Printing Office. Cloth, 4to, pp. 990.

(c) "The Liverpool Medico-Chirurgical Journal," including the Proceedings of the Liverpool Medical Institution, July, 1881. Liverpool Medical Institution.

(d) Is it the lung that errs in lobe or lobule? For that they have a pill, for *this* a globule, and I suppose a *botus*, if the lobe is in a state of hypertrophy!

his complaint." This is working the "double qualification" to some purpose. When the doctor misses with one barrel he at once brings his second into action. If it be true that so soon as *grave* symptoms declare themselves, homœopathy is discarded, and orthodoxy practised. What is homœopathy but a balloon sent up to attract notice? and when it has fulfilled its mission, is ignominiously bundled home in a cart! And who are its professors! (*On dit*.) Men who, failing of legitimate success ("hopeless of winning the mistress, woo the maid"), try to obtain it by what the profession considers illegitimate means, "*querenda pecunia primum est virtus post nummos*." For myself I know nothing of homœopathy further than what I read of it in Brande's "Dictionary of Science," &c., first published forty years ago, viz. :—

Homœopathy (Greek, *omoios*, similar, and *pathos*, feeling or affection).—"The homœopathic method of healing diseases was first proposed by Samuel Hahnemann in 1796. It consists in the administration of medicines presumed to excite in healthy persons symptoms similar to those of the disease to be treated, on the principle that "*similia similibus curantur*." Thus they maintain sulphur produces a pustular eruption on the skin, and therefore cures pustular eruptions. (I suppose sulphur would fail in syphilitic pustular, as it is not usually attended with *itching* (*pas de mangestation*, as Ricord used to say), and that quinine produces febrile symptoms and thus cures ague, and so forth. Not the least absurd part of this practice is the smallness of the doses in which the homœopathic remedies are administered, it being presumed that by infinite subdivisions the virtues of remedies are proportionately refined and exalted. A grain, for instance, of any remedy, such as aloe, is triturated with 1,000 grains of sugar of milk, when this mixture is complete a grain of it is diluted with 1,000 of the vehicle; and so of medicines which the ordinary practitioner administers in doses of one or two grains or more, the homœopathist prescribes in the quantity of a *millionth* or the *decillionth* of a grain, or even less. Hahnemann was also a believer in animal magnetism. It is not surprising, enthusiasts of this cast should occasionally start up; but it is remarkable they should find converts among persons in their "right senses." There is nothing original in homœopathic treatment. What is it but the treatment any allopath of experience adopts in cases where the mind and the feelings are more peccant than the body? The "*pilule micæ panis*," &c., prescribed for *malades imaginaires* are but the "*millionths* and the *decillionths* of a grain" in another form? Disease, whether real or fancied, always has offered, and always will, a fertile field for charlatanism. So difficult is it frequently to pronounce whether it exists at all, or the contrary. Hence, the success of the Irish country quack who attended all fairs and markets. If he happened to have a bad day, and saw any one looking specially hilarious, he frightened him into a consultation by informing him, with a grave face, "that he had a pain in his elbow, though he didn't feel it!"

ALLOPATH.

Obituary.

RAWDON MACNAMARA, JUNIOR.

WE greatly regret to hear from Trinidad of the untimely death of Dr. Rawdon MacNamara Son of Mr. MacNamara, of Dublin, Representative of the Irish College of Surgeons in the Medical Council. In his studentship this promising young gentleman divided with his brother the honours of the highest places at his Examination for the L.R.C.S.I. and shortly after he had obtained his medical qualifications he was appointed resident Surgeon to the Alnwick Infirmary, near Newcastle-on-Tyne, and upon his resignation of this post the regard of those amongst whom he practised was recorded by a handsome presentation. On his return to Ireland he became a demonstrator in the school of the Irish College of Surgeons, which office he held, until nine months since, he was appointed Colonial Surgeon at Trinidad. He died on the 7th of August of fever, which at first presented no serious symptoms, and thus the career of a young man who gave every promise of success and eminence in his profession was brought to an untimely end.

DR. REID, OF SLIEVEROE, CO. MONAGHAN.

WE regret having to notice this week the death of Dr. Reid. Deceased was Coroner for the Northern Division of this county, and Medical Officer for Kilmore Dispensary District. He died on the 16th instant, after a tedious illness, the immediate cause of death being inflammation of the lungs. He was a very clever physician, and had the entire confidence of the people in his district.

NOTICES TO CORRESPONDENTS.

OUR CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

DR. NORMAN KERR is thanked for returning communication which had been enclosed to him by error.

RESCULAP.—At page xix, last issue, a printer's error described this water as "chief among the *opes* group," it should have read *Opa* group.

ONE INTERESTED.—The examinations at the Queen's University, which commenced last Monday, will terminate on the 29th inst. A meeting of the University Court will be held on Oct. 13th for the purpose of conferring degrees.

MR. EVANS will find his inquiries answered on reference to the article in our present number on "Students' Books."

MR. E. A. SHEPHERD.—See reply to Mr. Evans.

MR. CROOKSLAND will find the subject of the multiplication of small hospitals very ably dealt with in a leading article in the *Times* newspaper of Friday last. We fully endorse the views therein expressed.

THE WHITWORTH DOCTORS.—A good deal of gossip, both in professional and "society" circles, has resulted from the sale by public auction last week at Manchester of the residence popularly known as the "Whitworth Doctors," the last of whom died some short time since without any direct descendants. These worthies of the "bone-setter" type have occupied a prominent position in Lancashire for the last century, and though legally unqualified men, they nevertheless, from time to time, have attracted patients from all parts of the world, and these in degree from dogs and horses to princes of the blood royal. The founder of the line, John Taylor, was originally a farrier, but "his skill in surgery and the treatment of broken limbs and crooked joints" brought him under the notice of George III., who sent for him to the Princess Elizabeth, from whose head he removed a local obstruction "which had resisted all the skill of the Royal physicians." Dr. Tait (now Archbishop of Canterbury) travelled up the Whitworth Vale to be cured of a slight malformation of the feet by these doctors. The Taylor family acquired wealth and property up in this moorland district, and kept a pack of hounds. Officers of the army and others used frequently to come from India and other remote foreign stations, and people have sailed from New Zealand and other colonies to be treated by this remarkable family; and in many cases report says they returned cured.

DR. CUMMINGS.—Received with thanks.

MR. T. R. B.—Probably a case of locomotor ataxy. On reference to a paper on this subject in our last volume by Dr. Stretch Dowse, you will find some data to guide you in your diagnosis.

A STUDENT should write to the dean of the college for further information, we have given enough to guide him in his choice in our "Students' Number;" for minor details we have no space.

DR. A. S. T.—The information is valuable, and will be utilized when the opportunity arises.

OUR STUDENTS' NUMBER—ERRATA.—Our attention has been drawn to one or two errors which crept into our "Students' Number" last week, which we hasten to correct. *Charing Cross Hospital Medical School.*—We stated the composition fee at this institution as £1 7s., it should be £1 7s. *London Hospital Medical School.*—In the list of scholarships and prizes at this institution we omitted reference to the establishment of a new prize for proficiency in chemistry. This prize has been founded by Mrs. Lethby to perpetuate the memory of her husband, the late Professor of Chemistry at this School, and is called the Lethby Prize, the annual value of which is about £35.

THE CAMBRIDGE EXAMINATIONS.—We are requested by Professor Living to announce that the examinations in Sanitary Science by the University of Cambridge, open to all whose names are on the Medical Register of the United Kingdom, will begin on October 4. The names of candidates must be sent to Prof. Living, Cambridge, before the 29th inst.

OPERATION DAYS AT THE LONDON HOSPITALS.

(For the guidance of Provincial Practitioners in Town.)

MONDAY.—Metropolitan Free, 2 p.m.; St. Mark's, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Westminster Ophthalmic, 1.30 p.m.
TUESDAY.—Guy's, 1.30 p.m.; Westminster, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Westminster Ophthalmic, 1.30 p.m.; West London, 3 p.m.; St. Mark's, 9 a.m.; Cancer Hospital, Brompton, 3 p.m.

WEDNESDAY.—St. Bartholomew's, 1.30 p.m.; St. Mary's, 1.30 p.m.; Middlesex, 1 p.m.; University College, 2 p.m.; London, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Great Northern, 2 p.m.; Samaritan Free, 2.30 p.m.; Westminster Ophthalmic, 1.30 p.m.; St. Thomas's, 1.30 p.m.; St. Peter's, 2 p.m.

THURSDAY.—St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Charing Cross, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Hospital for Diseases of the Throat, 2 p.m.; Westminster Ophthalmic, 1.30 p.m.; Hospital for Women, Soho, 2 p.m.; London, 2 p.m.

FRIDAY.—King's College, 2 p.m.; Westminster Ophthalmic, 1.30 p.m.; Royal London Ophthalmic, 11 a.m.; Guy's, 1.30 p.m.; St. Thomas's (Ophthalmic Department), 2 p.m.; East London Hospital for Children, 2 p.m.

SATURDAY.—St. Bartholomew's, 1.30 p.m.; King's College, 1 p.m.; Royal London Ophthalmic, 11 a.m.; Westminster Ophthalmic, 1.30 p.m.; St. Thomas's, 1.30 p.m.; Royal Free, 9 a.m. and 2 p.m.; London, 2 p.m.

Vacancies.

Brompton Consumption Hospital.—Lady Superintendent. Salary, £100, with board, &c. Applications by Oct. 5th to the Secretary. (See Advt.)

Manchester Clinical Hospital.—House Surgeon. Salary, £30, with board. Applications to the Secretary, 26 Burton Arcade, by Oct. 5.

Metropolitan Asylums Board.—Assistant Medical Officer for the Leadenhall Asylum.—Salary commencing at £120, with board. Applications by Oct. 4th to the Clerk of the Board, 37 Norfolk Street, Strand, London, for printed form. (See Advt.)

Nemagh Union, Toomavan Dispensary.—Medical Officer. Salary, £100, and £10 as Medical Officer of Health. Election, Oct. 11.

St. Columb Major, Cornwall.—Medical Officers for Districts 3 and 4. The salary attached to No. 3 is £18 10s., and to No. 4 £21, with the usual extras. Applications to the Clerk to the Guardians.

Western Ophthalmic Hospital.—Surgeon. Honorary. Applications to the Secretary, 165 Marylebone Road, London.

Appointments.

GREEN, Dr., Medical Officer to the Emsay Dispensary District.

LANE, J. E., M.R.C.S., Demonstrator of Anatomy at St. Mary's Hospital Medical School.

MACDONALD, J., M.D. Ed., Medical Officer for the Pariah of Walton, in the Chertsey Union.

MORISON, J., M.D., M.R.C.S., 8 Sc. Cert. Camb., Medical Officer to the Workhouse, and Medical Officer and Public Vaccinator to the First District of the St. Alban's Union.

O'CONNOR, T., F.R.C.S.E., Medical Officer of Health for the Cambridge Urban Sanitary District.

PHILLIPS, S. M. D., Demonstrator of Anatomy at St. Mary's Hospital Medical School.

POLLARD G. E., L.R.C.P. Ed., L.R.C.S. Ed., L.M., Medical Officer of Health for the Balldon Urban District, Yorkshires.

POWELL, G. B., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer to the Nottingham Union.

RIDGE, J. J., M.D. Lond., L.R.C.P., M.R.C.S., Medical Officer of Health to the Enfield Urban Sanitary Authority.

SHEPHERD, H. R., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer for the Fontmell District of the Shaftesbury Union.

STRAHAN, S. A. K., M.D., Assistant Medical Officer to Northampton County Lunatic Asylum, Berrywood.

WILLIAMSON, E. L., M.B., C.M., L.R.C.S. Ed., Medical Officer for the Pariah of Dalry.

Births.

GROSS.—Sept. 24, at Walworth, S.E., the wife of Chas. Gross, L.R.C.P. Lond., of a daughter (still-born).

MARTIN.—Sept. 9, at Trevor Hill, Newry, the wife of S. Edgar Martin, A.M., M.D., of a daughter.

O'CONNELL.—Sept. 17, at Thornfield, Hastings, the wife of Surgeon-Major E. O'Connell, A.M.D., of a daughter.

TURTLE.—Sept. 19, at 85 High Street, Homerton, the wife of James H. Turtle, M.D., of a son.

Marriages.

AITKEN—BOUCH.—Sept. 21, at St. George's, Hanover Square, London, Lauchlan Aitken, M.D., of Rome, to Fanny, elder daughter of the late Sir Thomas Bouch, C.B.

FAHIE—HARTFORD.—Sept. 12, at Glashtule, Charles Fahie, M.D., Esq., co. Dublin, to Fanny, second daughter of John P. Hartford, Esq., Kilkenny.

MACROBIN—JONES.—Sept. 14, at the Parish Church of Clontarf, Surgeon-Major Macrobin, A.M.D., only son of the late Prof. Macrobin, of Aberdeen University, to Annabella, widow of the late Captain Charles Gray Jones, R.N.

TAYLOR—ATKINSON.—Sept. 22, at Trinity Church, Rathmines, Thomas Cathcart Taylor, B.A., T.C.D., &c., Brookboro', co. Fermanagh, to Isabella (Baggie), youngest daughter of the late Arthur Atkinson, Kilkenny, co. Down.

Deaths.

BARRY.—Sept. 15, at Tunbridge Wells, J. Milner Barry, M.D., F.R.C.P., son of the late J. Milner Barry, M.D., of Cork, aged 67.

IRVING.—Sept. 20, at Long Bennington, Lincolnshire, after a week's illness, William Bell Irving, M.R.C.S., aged 70.

RAWBONE.—Sept. 19, at Athole House, Tooting, Surrey, George Rawbone, F.R.C.S., in his 83rd year.

REED.—Sept. 18, at Slieveroe, Monaghan, Robert Harton Reed, M.D., in his 34th year.

WINN.—Sept. 23, at 81 Harley Street, London, W., Emelyne Hale, the wife of J. M. Winn, M.D.

Original Communications.

REMARKS ON SOME RECENT AND PRESENT VIEWS REGARDING FEVERS IN INDIA.

By Surgeon-General C. A. GORDON, M.D., C.B.,
Honorary Physician to the Queen; late in Medical Command of
Her Majesty's Forces, Madras Presidency.

(Concluded from page 278.)

In the *Dublin Journal of Medical Science* for March, 1881, p. 27. Dr. Henry Kennedy asks, "has the constitution of individuals in whom typhoid fever occurs been sufficiently recognised?" He thinks not. He believes that this type of fever chiefly occurs in persons who, if not of a strumous constitution, are chiefly allied to that state. The number of individuals suffering from typhoid fever who have a very fine skin and a high colour in their cheeks is very remarkable; their frame, and particularly chest, is not very robust. Exceptions do occur. The similarity of the lesions which occur in tubercular phthisis and enteric fever, to his eye seems to be of the very closest. Catarrhal pneumonia often accompanies enteric fever, and often ends in phthisis. He observes that "all diseases exhibit themselves in what may be called cycles, but none more strikingly than fever;" that "typhoid fever is not the localised disease which many suppose it to be." He alludes to Dr. Harley's paper, which proves that other fevers beside typhoid may implicate the lower part of the ileum and neighbouring parts. He describes typhoid fever as constituting a state.

Surgeon-Major Jackson, C.B., (a) remarks that in Natal a difference existed in the opinions held regarding "enteric" fever by medical officers in the field and those at the base hospital; the former looked upon it as malarial, the latter from the character of post-mortem lesions, designated by them "enteric lesion," pronounced the fever "typhoid." The chief point of

discussion with regard to such cases appears to have been based upon the character of temperature curves during life and of lesions found after death.

Dr. Nixon (a) alludes to a case of "anomalous" fever, in regard to which "highly competent medical men arrived at widely different conclusions, opinions being divided as to whether it was a case of cholera, scarlatina, maligna, or enteric fever." He states that "in many cases of undoubted scarlatina post-mortem examination reveals engorgement and other pathological change in Peyer's patches and the solitary glands of the intestine" (p. 478). His further remarks have an especial importance: "There is," he says, "an opinion which finds currency that the same infective source can give rise to different and distinct diseases in different individuals according to their susceptibilities and peculiarities of constitution, producing in one typhoid, in another scarlatina, in a third diphtheria, and so on. This view, of course, militates against the 'germ theory' of disease, but labours under the disadvantage of being not proven in any particular case." But, it may be asked, has the germ theory been actually demonstrated and proven in any particular case? Who can definitely reply in the affirmative? Dr. Nixon concludes by remarking that "there is strong evidence that, at any rate in the case of some diseases, a certain specific germ, and no other is capable of exciting them." But what of enteric and typhoid fever, considering what has just been quoted from Drs. Nixon and Bernard as to the number of diseases which simulate enteric fever and are simulated by enteric fever? From these remarks the circumstance often alluded to is further shown, that similar characters, conditions, and complications as by some writers are held to constitute specific typhoid or enteric fever, occur also in other diseases, thus leading "highly competent medical men to arrive at widely different conclusions" on the subject of these characters as diagnostics. Dr. Nixon has good reasons also for his belief that diseases due to the same causes

(a) *Dublin Journal of Medical Science*, January, 1881, p. 17.

(a) *Dublin Journal of Medical Science*, January, 1881, p. 475.

become modified in their phenomena according to "susceptibilities and peculiarities of constitution;" it is therefore easy to follow him to the conclusions he arrives at, namely, that "this view militates altogether against the *germ theory* of disease."

Dr. Dedrickson (a) notices that during the months of March, April, and May, less frequently in June and July, continued fever is very prevalent among the shipping of the port of Calcutta. He assigns as causes vicissitudes of temperature, excessive heat, intemperate habits, and exposure to the moist night air of the above months, the most frequent of them being exposure to excessive heat (p. 481), either direct or indirect, the former while the men are at work, the latter while in their ill-ventilated bunks. In that continued fever the bodily temperature varies from a shade above normal to 103 or 104 degrees, but if beyond the latter serious complication is present. Such cases are usually brought about by direct exposure to the rays of the sun; the face is deeply flushed, the dry heat met with in simple continued fever intensified; this form is very common among intemperate people, and very fatal. Dr. Dedrickson remarks that continued fever is sometimes accompanied by diarrhoea, but only in mild cases; also that "it appears to relieve the head symptoms."

Dr. Goodall Nasmyth (b) asks "can we positively say that enteric fever may not arise where we can neither trace any contamination of the water supply nor any defect in the drainage, where there is no chance of it having been imported by its different vehicles?" He describes the occurrence of the disease in four different districts, all in a bleak, cold part of the country, 300 to 400 feet above the level of the sea; climate cold and damp; soil, stiff clay, in some places deep morasses and marshes; drainage, good. He states, however, that the first case occurred in a house at the front of which there was a fetid pool that had stood for months, although up to that time without causing fever. After one case happened others speedily followed. Adverting to the exemption of workers in sewerage and poudrette he observes: "It may not happen to them for thirty years, or it may be any day." His experience is, that in the worst constructed and dirtiest houses, the cases were the most severe and most tedious. On the subject of treatment he observes that different cases must be treated in different ways according to symptoms, age, and condition of the patient. "Symptoms have to be treated by the ordinary remedies, quinine or salicine for high temperatures;" cold sponging he considers better than either.

From all of which particulars these points appear, namely, that the non-specific origin of typhoid fever under particular circumstances is implied; that in the instance related importation of the disease from a previous case is not alluded to, and consequently may reasonably be assumed not to have been traceable; that the latitude expressed with regard to the occurrence and non-occurrence of *typhoid* fever among the classes of persons enumerated as employed in offensive occupations indicates on their part no special liability to that disease over that of those not so employed; but that, as with regard to disease in general, so *typhoid* fever when it does occur, proves more severe and protracted in places where the sanitary conditions of the people are bad than where they are more satisfactory. The remarks on the use of quinine deserve to be noted in connection with what has already been stated regarding that drug as a test of malarial as against specific enteric fever.

From the particulars now given the following are the deductions they support, namely:—

1. When in 1859 the occurrence of *typhoid* fever in a specific sense was for the first time recorded among British troops in India, it was looked upon as an

autumnal fever, the cases resembling *remittent* fever, which, together with intermittents, prevailed at the same time; in fact, that all forms alike were seasonal, climatic, or malarial, according to the sense in which these expressions are applied.

2. In the fatal cases recorded the post mortem appearances differed in no respect from those usually found in cases of endemic fever attended by "intestinal complications." (See 36.)

3. The expression *adynamic*, as applied to a stage or condition of autumnal fever, is applied as a synonym of *typhoid*. Thus the distinction is not clearly indicated between the indication of a mere condition occurring in the course of climatic fever, and a *specific* form of disease assigned to a specific cause. (See 8.33.)

4. In the treatment of those cases of *autumnal*, climatic, or malarial fever, the importance of quinine is specially noticed.

5. In addition to climatorial and seasonal influences, the troops were exposed to generally unsatisfactory hygienic conditions. (See 29, 36, 39.)

6. But the year was described as an unhealthy one; that is, conditions usually indicated by the expression, "epidemic influence or constitution," were in operation beyond such connected with season and locality which, under ordinary circumstances, are present and recognised. (See 39.)

7. Some of the cases given appear to have been of hæmorrhagic or malarial dysentery, such as in former years prevailed, when imperfect hygienic conditions added their influence to that of *climate* and season.

8. The expression, "typhoid remittent," again occurs to indicate a *condition*, rather than a specific form of fever due to a special cause. (See 3, 33.)

9. A relationship between particular fevers and types of fever, and geological conditions of locality, is indicated.

10. The occurrence of epidemics of contagious fever is related; the character of the fever described as typhus, typhoid, and relapsing—that is variously designated by different observers. (See 12, 20, 30.)

11. Of some illustrative cases given as occurring in India, one presents the ordinary indications of endemic and otherwise non specific fever; one of gangrenous dysentery; one of dysentery due to indiscretion on the part of its subject.

12. That *specific* typhoid fever occurred, however, in India, appears from particulars given with regard to Jutog and Simla. At the same time the occurrence of the disease so designated deserves to be noted in connection with what is recorded as above under deduction. (See 10, 29.)

13. Further illustrative cases in India are given. They appear to include those where ulceration of the intestine, or other bowel complication, occurred in the course of endemic fever. (See 2, 36.)

14. Thus, among cases included under the head of *typhoid* fever are those of *adynamic*, *remittent*, *autumnal*, or malarial fever, hæmorrhagic dysentery, gangrenous dysentery, typhus and relapsing fevers. (See 26.)

15. Cases recorded as of *typhoid* fever in England indicate no common ground upon which they are so designated.

16. The occurrence at Bareilly of an outbreak of what is designated *enteric* fever is distinctly attributed to the "effects of climate upon young and newly-arrived soldiers." Explanation is wanting as to the grounds upon which a designation indicative of other and specific causation was applied; or of why intestinal phenomena were looked upon as other than "complications" occurring in the course of endemic fever. (See 29, 30, 35, 36, 38, 39.)

17. With regard to cases said to be of "enteric" fever occurring elsewhere, the statement occurs that the distinction between them and those returned as continued

(a) *Idem*, p. 481.

(b) *Edinburgh Medical Journal*, December, 1880, p. 499.

and remittent, is more a question of gravity of the individual case than difference of symptoms. (See 40.)

18. Hence naturally the question raised by the Army Sanitary Commission, "Is there such a specific fever as enteric fever at all?" and the further question with regard to post mortem appearances as to whether those found in typhoid fever are special to a specific form of fever as are found in Indian non-specific fevers.

19. A series of cases, described as of enteric fever, occurred "sporadically" in the Madras Presidency, and under circumstances adverse to the theory that they were due to contamination of milk or water. (See 24.)

20. According to statistics given, the greater prevalence of fevers among British troops in particular seasons than in others leads to the remark that such years were "epidemic years," thus confirming deduction 10, (See also 3, and 30).

21. There is no actual foundation for the impression entertained by some present writers that the origination of "enteric" fever in India is "due to a more intelligent and exact differentiation" of fevers on their part than on that of their predecessors. On the contrary, a considerable number of forms and conditions occurring in the course of fever, have of late years come to be so designated.

22. Symptoms during life, and pathological changes such as are said to characterise specific enteric fever, exist also in cases of fever, non-specific as regards its origin, except than that it is due to endemic, climatorial, or malarial influences, as stated in deductions 1, 2, and 3.

23. But, as in Madras, so in England, the contamination theory is acknowledged to be insufficient to account for the recurrence of enteric fever under all the circumstances in which it prevails. (See 19.)

24. That as regards India, specific causes being thus eliminated, it becomes necessary, as it is sufficient to fall back upon the more general included, for the want of more precise definition under the name of climatic, endemic, and epidemic influences acting upon certain individual conditions, including early manhood and recent arrival in the country. (See deductions 4, 5, 6, 20, 35, 39.)

25. That, besides these circumstances, individual diathesis has an important relation to type of fever presented in different cases. (See 29.)

26. That similarities exist between enteric fever, gastric fever, enteritis, typhus fever, and poisoning by tainted meat, of so close a nature as hardly, if at all, to admit of distinction being drawn between these several affections. (See 14.)

27. That these are in some instances included under the term "enteric" fever. (See 7, 10, 14, 16, and 17.)

28. The ingestion of diseased meat may produce symptoms resembling cholera or enteric fever; so may that of tainted or decomposed meat.

29. In Bermuda and elsewhere the local condition theory is insufficient to explain the occasional prevalence of epidemics; hence the theory of epidemic influence is there accepted. (See 10, 16, 20, 39.)

31. The term "simple," as applied to protracted "continued" fever, is a misnomer for the reasons given.

32. English views of causation of "enteric" fever are not now universally accepted as applied to tropical and subtropical countries.

38. The change that has taken place in regard to nomenclature is due rather to a name than to a reality. (See 3, 8, 4.)

34. In tropical and subtropical countries there is a relation between types of fever and season.

35. And also to individual diathesis. (See 5, 16, 24, 29.)

30. Enteric lesion may be found in several forms of allied fever. (See 2, 13.)

37. The relation of "enteric" fever to youth and recent arrival is again noticed. (See 16.)

38. And its occurrence in native Indians.

39. An opinion is expressed as to the specific nature of the poison of "enteric" fever in India; modifying influences of climate being also allowed. (See 5, 6, 12, 16, 20, 24, 30.)

40. According to a standard given, malarial fever attended by gastric complication is designated "remittent" fever; with intestinal complication "enteric." (See 17.)

41. Doubts are expressed as to the actual nature of the cases on which the pythogenic theory was based. (See 33.)

42. Evidence is adduced to indicate that specific "enteric" fever is contagious; yet differences of opinion are expressed. (See 45.)

43. Similar differences of opinion are acknowledged to exist regarding the etiology of "enteric" fever.

44. The period of incubation is variously stated as twenty-one and fifty-four days.

45. Opinions are adduced in favour of *de novo* origin of enteric fever, independent of specific origin. (See 42.)

Consequently: Seeing the great differences of opinion thus shown to exist with regard to the several points enumerated, the conclusions are natural that these differences are irreconcilable upon, and with the pythogenic and specific theory of the form of fever known as enteric; also that there is ground for belief that a series of phenomena in all respects similar to those which in temperate climates occur as manifestations of a distinct form of fever take place as conditions occurring in the course of endemic or climatorial fevers, whether sporadic or epidemic in sub-tropical or tropical climates. Further, that in temperate, as in tropical countries, neither are causes of a "specific poison" nature proved, or needed to be in operation for the production of the phenomena enumerated; nor are those phenomena limited to only one distinct form of disease but occur as conditions of, and complications in, the course of several.

NOTES ON THE PATHOLOGY OF RICKETS. (a)

By DR. ADOLPH BAGINSKY, Berlin.

1. THE clinical experience, that congenital rickets is met with, that the majority of children born with congenital syphilis become rickety even under the best nursing, that rickets arise as a sequelæ of grave febrile disease, and of grave chronic gastro-intestinal disorder, that it arises in consequence of bad nourishment and want of fresh air, the further experience that rickets is associated with considerable troubles in the nervous system (Larygismus stridulus, hydrocephalus, hypertrophy of the brain), all combine to exclude, from a clinical point of view, the possibility of explaining the disease, by a simple deficiency of the inorganic constituents of the bone.

2. The opinion that rickets consists only in a deficiency of the lime is also excluded by the fact that the proportions between the inorganic and organic (minus fat) constituents of the bone are so considerably altered—160:100 instead of the normal 563:100—that supposing the lime is eliminated from the food of the child for a whole year, the proportion would by a proximate estimate be found to be still 513:100.

3. In a certain opposition to these clinical experiences are the experimental studies of some authors (principally Roloff in Berlin), who have proved that rickets may be produced in animals by withdrawing lime from the food.

I have repeated these experiments, and found:—

(a) Read before the International Medical Congress, August, 1881.

a. Simple elimination of lime from the food produces, in fact, considerable changes in the bone.

b. The change appears macroscopically and microscopically about the same as a slight ricketty change.

c. The degree of change produced is, as it is shown by anatomical, and principally by chemical, examination, only a mild one.

4. If, besides the elimination of lime from the food, lactic acid is added to the latter, the alterations are considerably increased. This is shown by:—

a. By the macroscopical and microscopical examination of the bone.

b. Especially by the chemical test.

5. The considerable influence which the addition of the lactic acid has in connection with the elimination of lime from the food, proves that withdrawing of the lime alone cannot be the determining cause.

6. In fact, both factors, the elimination of lime and the addition of lactic acid have this in common, that they produce an alteration in the general nutrition, the one by withholding an indispensable constituent of the organism. The other by the introducing a substance apt to disturb the digestion.

7. The lesion of the bones is only the most prominent feature, because the disturbance of the general nutrition happens in a time when the growth of the bone is most active.

8. Further is it possible to prove that neutral solutions of peptons have the faculty of dissolving lime.

9. This faculty of the peptons shows how in children suffering from an alteration in the composition of the blood in consequence of faulty nourishment, lime combination may be dissolved in the growing and ossificating bone, and carried away from it.

10. The elimination of the carried off lime combinations takes place through the intestinal canal, as can be shown by the examination of motions from ricketty children.

11. Rickets is, therefore, a dyscrasia originated by an alteration in the general nutrition which may be caused by various noxious influences working upon the infantile organism.

12. In accordance with this view are the well-known successful therapeutic results of such remedies which are suited to improve general nutrition, especially good hygienic conditions, normal nourishment, the use of baths, and tonic medicines.

OPIMUM AS A LUXURY, AND IN THE TREATMENT OF DISEASE.

By HERBERT PARSONS, M.R.C.S.,

Formerly Resident Medical Officer St. Mary's Hospital, London.

(Continued from page 276.)

SINCE the introduction of chloral hydrate and bromides, opium is less used as a simple sleep-producing agent, but in cases where pain is the cause of the sleeplessness, it is still our best narcotic. In cases where the heart is very weak, whether organic disease is present or not, opiates are usually to be preferred to other narcotics, and sometimes are the only ones admissible, though the presence of kidney disease contra-indicates their use.

In shock, and extreme debility, alcohol and opium are the only narcotics that can be used, and those only with care.

Unless absolutely necessary, it is inadvisable to commence the use of opium or morphia in chronic diseases, where their use is likely to be continued for a long time; for, in these cases, the doses have to be continually increased to produce sleep, and finally, when the disease is subdued, it may happen that so habituated have they become to these narcotics that their use remains imperative.

In all cases where there is very anæmic tendency, even

if only temporary, the exhibition of morphia and opium is attended with extreme danger, but if requisite, small doses are of great service.

In ordinary cases, opium in pills produces sleep with the minimum quantity of the drug and is followed by less headache and nausea than other forms. Dover's powder is also highly to be recommended. Morphia by injection possesses the advantage of immediate action, and the same salt is useful in the form of pills.

If opiates be combined with chloral, or with bromide of potassium, less quantities of each drug is required, and the effect produced is often better than when either is given singly. A combination of tr. opii, with brandy, hot or cold, is often the best narcotic for old and feeble, or slightly cyanotic subjects. Very small quantities of opium will often give sleep better than anything else, where the patient is kept awake by an irritable cough, or other annoying nervous symptoms.

For the purposes of relieving pain, opium and its derivatives are most extensively employed, since, for that purpose, its effects lasts longest, and short of absolute anaesthesia are the most perfect. It is for this that the hypodermic method is so valuable; by its use biliary and renal colic, neuralgia, pleurodynia, and other acute pains, are at once cured, or, at least, rendered bearable, although, if the pain be great, huge quantities have sometimes to be given before accomplishing the desired object. There are but few diseases in which severe pain is present which will not be benefited by morphia, and no fear of the results need be entertained unless renal mischief is present. In all cases, it is well, if the patient be quite unused to opium, to begin with a small quantity, for if this is too small to produce an effect, it is easy to repeat it very soon, while, for all we know, we may have a peculiarly sensitive person to deal with, and a full dose might produce unexpected results. I have seen one-sixteenth of a grain of morphia produce death in a child who had taken the same amount previously, while the kidneys were acting freely, with advantage. In another case of an adult, a first injection of a quarter of a grain produced alarming toxic symptoms, and if vigorous measures had not been taken, would, no doubt, have proved fatal.

In opium we have not got one of those specific remedies, such as quinine, which may be given by even ignorant hands with a certainty of its producing its curative effects; such specifics unfortunately for human suffering, though, perhaps, well for the physician, are rare. But this remedy to be successful must be administered by scientific hands with skill and caution, otherwise the result may be ill instead of good. Let its physiological effects be borne in mind, and then let them be applied to correct diseased conditions, letting our guide be the light of scientific truth rather than the dogmas of prejudice.

Instead of spending time in enumerating all the well-known uses of opium in the manner of text-books, this paper shall rather devote some space in considering the effects of the drug on some organs in health, and showing the deductions that may be drawn for its use in disease.

It has been stated before, that opium, as well as strengthening the systole of the heart, causes the muscular coats of, at least, the smaller arteries to be sufficiently paralysed to allow the calibre of those vessels to be enlarged. Thus is the warm glow, and flush of the skin and face, produced, and with it the diaphoresis. This effect on the skin is a lasting one. But it is a proved fact that after a little time the mucous membranes become paler and drier, so it must be conceded that opium contracts rather than dilates the internal vessels. In the same way the brain is at first excited, but afterwards subsides into a state of somnolence. Here, then, the analogy is complete, and we can therefore assume that the cerebral blood vessels are finally reduced to a state of contraction; actual observation has also proved that during sleep, and when under the influence of opium, the brain is anæmic. Let us also look at the symptoms of want of proper blood supply to the brain, however that want is

produced. All observers agree in giving the following symptoms:—Dizziness, headache, thirst, sleep, finally resulting, as if the anæmia be produced suddenly, syncope, vomiting, and convulsions occur. The symptoms are nearly exactly the same as those produced by opium; especially do we see the resemblance when we consider that large doses of opium, and injections, not unfrequently produce faintness, vomiting, and even convulsions, but as opium acts as a stimulant to the heart, syncope is less likely to follow than if the cerebral anæmia was otherwise produced. Again, in chronic want of blood supply, the brain gets reduced to a weak and irritable state during which delirium is easily induced; this is, in fact, the same state to which opium eaters come after long indulgence.

It may seem, at first sight, highly improbable that the same thing should produce dilatation of the vessels in one part, and contraction in another; and perhaps one will be unwilling to believe that the brain is in a bloodless state, while we can see that the face is flushed, and feel the external surface hot and glowing, more especially when it is well known that hyperæmia of the external parts of the head corresponds with a hyperæmia within. But look at a few facts; in the first place we see that during sleep (when the brain is anæmic) the face is flushed, and perspiration breaks out, while the pulse often grows softer and more rapid, thus showing the paresis of the vaso-motor nerves. It must be considered also that the heart's action being increased under the influence of opium, more blood is necessarily sent up to the carotids, and if this meets an obstruction in the contracted branches of the internal carotids, naturally more blood than usual will find its way into the branches of the external carotids, where it meets not only no obstruction, but encouragement, owing to the dilatations of its terminals. In other parts of the body, the conditions as to fulness of the extra and intra-circulation do not correspond, we shall therefore cease to believe that fulness of the vessels of the face and scalp must correspond with the same conditions in the brain. Graves has left an account of the post-mortem examination, which goes to prove the same thing. In opium poisoning we see the face flushed, the lips red, and the pupil contracted, all showing the state of paralysis of the sympathetic, and the face will not grow pale unless the strength of the heart begins to give way, giving warning of approaching asthenia. Opium then causes contraction of the cerebral, and dilatation of the cutaneous vessels, as well as increases cardiac action, together with astringent effects on the mucous membranes; but besides this, it also diminishes the secretions of the viscera, such as the liver and kidneys, as can be seen by the smaller amount of bile and urine passed while the body is under its influence.

For an example of the good which may be expected from the drug under consideration, let us take a case of typhoid fever in an advanced stage. What are the morbid conditions here which render death imminent? First, a weak heart and feeble circulation; second, a local drain from the system by diarrhoea; third, a brain in a state of congestion, and, consequently, the patient is suffering from sleeplessness and muttering delirium; we have also complete anorexia, a dried furred tongue, and a considerable amount of fever. Now, if small doses of opium be given, either by the mouth, or by the rectum, the following are the results to be hoped for—nay, to be positively expected—if the system be not too far exhausted to answer to the stimulant. The weakening and draining diarrhoea is stopped; the heart is strengthened, and the circulation improved; more blood is sent into all the organs, giving them pabulum wherewith to perform those offices without the proper performance of which life must cease. The cerebral vessels are contracted, and the low muttering delirium is superseded by a refreshing sleep, after which the patient will awake sensible, in no discomfort, and with a more favourable state of the alimentary organs; thus we avert the danger of death from asthenia, into which he was fast sinking, and place him

in the best condition for recovery. Here opium is no specific, nor exerts no strictly curative influence on the disease itself, yet, undoubtedly, by means of it, we are able to save a life that would otherwise be lost. Here a case of typhoid fever has been taken as an illustration, but many asthenic forms of fever are equally benefited by it. But in these cases we must avoid making the mistake of supposing that brain symptoms are always the result of derangement of the cerebral circulation. There are numerous cases in which we see delirium or dementia, or other symptoms pointing to affection of the brain, but in which there is present neither anæmia nor hyperæmia of that organ. In these the symptoms are the result of one of two courses: either the blood circulating through the cerebral vessels is of a character directly irritating to the brain, as in some states of high fever, and so on; or else the brain cells themselves are in a state of hyper-irritability, so that normal impressions produce abnormal results. In the first class opium can hardly be expected to do much good, but still, sometimes, by lessening the quantity of blood which is irritating them, and, perhaps, by a directly sedative effect on the molecular elements of the brain, it is of service. In the second kind of brain disturbance it, also, sometimes is of use, we must therefore assume the opium, besides making the brain anæmic, has a directly sedative effect on the cells. Sometimes, in these conditions, small doses will increase the excitement, while large doses will soothe.

It has been long a maxim with practitioners, that in some cases of cerebral excitement, opium, instead of doing good, does an infinite amount of harm. The cases in which opium is to be shunned, are those of delirium superseding on head injuries, occurring in strong robust subjects. Delirium, of a sthenic character, often follows injuries to the head; in these meningitis or concussion are sometimes the cause of the symptoms in either case, opiates, as, in fact, all stimulants are liable to do much harm by increasing the excitement and the fever.

In meningitis and encephalitis the blood-vessels are congested, but the vaso-motor nerves are paralysed, and, if opium be given, will not react to its stimulation; in these diseases, then, opium is useless, but not only so, but as most practitioners consider, painful. In some person's opinion, opium, combined with mercury, is useful in inflammation of the brain and its coverings.

In former days, when venesection was rife, mercury, combined with opium, enjoyed great reputation as anti-phlogistic remedies. To-day our opinions on this point have undergone great revolutions, and now these remedies are supplanted, in some cases, by tonic treatment, in others, by such drugs as aconite and belladonna, whether advantageously or not remains an open question. Yet it must be conceded that opium has a potent effect in contracting, at any rate, normal blood-vessels in some parts of the body, quite as much so as belladonna. The whole subject of the treatment of inflammations has suffered, to a great extent, of late years; and even the term anti-phlogistic, so much used by old writers, is unused by many of the modern authors; yet it is a convenient term, and to illustrate better the use of opium I will digress a little to show the different classes of anti-phlogistic measures that may be adopted.

All remedies applied for the arrest of inflammation are given with a view to reduce the quantity of blood contained in the paralysed vessels of the inflamed part. It is true that the tissues are supposed also to take part in the derangement, yet, except, perhaps, in chronic cases, and a few specific inflammations, we have no remedies which will enable us to act on these. We can then class anti-phlogistics into four classes, according to the way they diminish the quantity of blood in the inflamed organ or area. They do it, then, in these ways:—

1. By reducing the total quantity of blood by venesection, and low diet, and perhaps mercury.

2. By depressing the heart, and slowing the circulation, so that more blood is retained in the venous system, and less sent to the arterial. Such things as aconite, anti-

mony, veratria, and also the remedies of the first-class effect this.

3. By dilating all the vascular systems of the body, and thus drawing, as it were, the blood from the affected part. To do this we have aconite, diaphoretic, antimony, and opium.

4. We have various drugs, and other mechanical means of contracting the arterioles of the congested part itself, such as by applying cold, and administering belladonna, ergot, digitalis, opium, &c. Brief consideration will show that there are drawbacks to the employment of any of these methods, and also that some are adapted to one class of cases, and some to others. Thus, for instance, in the first class, the subsequent effects, after lowering the vitality, is likely to prove dangerous in any but sthenic cases. The second method is liable to the same objections. The third method is admirably adapted for small and local inflammations, as of the tonsils or larynx, for here, as can be readily seen the large area to which depletion can take place, is competent to contain all the blood from a small part, while in a large organ, the amount taken away would be comparatively small. In the fourth case we must remember, that except at the very commencement, the vessels in inflammation lose their tone so far that they will contract to no stimulus; yet here the contracting agent may, by contracting the surrounding vessels, prevent spreading of the inflammation. Experience, as well as principle, shows that one or two methods combined are more efficacious often than one alone, and this combination of methods can be sometimes effected by one agent, which has two or more different actions. So, for instance, in some cases we dilate the peripheral vessels by diaphoretic, and contract the vessels of the inflamed part by external applications or internal remedies, and sometimes also lower the heart's action by strong purges, or other means; in asthenic cases we omit the last measure. Now in what inflammatory cases should opium be used; we have seen that it acts in the third and fourth method, but we must not forget that it is a cardiac stimulant, hence is inapplicable in sthenic cases. Local inflammations, as of the tonsils, are cured readily by the continued action of opium, unless it is a very acute case, with tendency to suppuration; but in these cases it is inferior to remedies, such as aconite and belladonna, and others, and it often produces constitutional disturbances, which are worse than the disease itself. It is, therefore, in asthenic and in chronic cases that opium is valuable. In severe cases, where the tendency is to death by asthenia, opium is above all valuable; in peritonitis, where it also gives rest by stopping the peristaltic action of the bowels, its value is universally recognised. In other cases of inflammation, as pneumonia, where death usually occurs by asphyxia, its use is attended with bad consequences under some conditions. But independently of its anti-phlogistic actions, opium is largely used in acute inflammations for the purpose of easing pain and giving rest. In all surgical procedures having to do with the peritoneal cavity, opium is our great safeguard; and, in fact, it is as valuable, or more so, to the surgeon as to the physician.

(To be continued.)

STIMULANTS IN WORKHOUSES DURING 1880.

By NORMAN KERR, M.D., F.L.S. Lond.

On the motion of Mr. Whitworth, M.P., the House of Commons ordered a return showing the amount and value of alcoholic stimulants used in the several workhouses in Ireland during the year 1880, the number of sick persons treated, and the death-rate in each workhouse. This return has recently been issued. From it we learn that in the province of Ulster, 25,030 sick persons were treated during the year. Of these, 2,498 received stimulants to the value of £1,014 14s. 9½d. In the province of Munster 49,616 persons were treated, of

whom 15,749 received stimulants to the value of £3,750 19s. 9d. In the province of Leinster 35,066 persons were treated, of whom 26,954 received stimulants to the value of £5,380 16s. 5½d. In the province of Connaught 10,486 persons were treated, of whom 2,950 received stimulants to the value of £1,698 17s. 7d. In all Ireland 120,198 persons were treated, of whom 48,151 received stimulants to the value of £11,845 8s. 7d.

If we group these figures, under three general heads, with those representing the deaths in each workhouse of the whole number of sick persons under treatment, there is presented an apparent decreased rate of mortality among those who received the lowest average amount of stimulants. There were 47 workhouses where the average cost of stimulants for each pauper in the total number of the sick was under 1s. The average rate of mortality was, in this group of 47 workhouses, 8·4 per cent. In the next group, comprising 55 unions, with an average cost of stimulants for each sick pauper ranging from 1s. to 2s. 6d., the rate of mortality was 11·3 per cent. In the third group, however, though the average cost was much higher than in the second group, the rate of mortality was lower. While the average cost for each sick pauper in the third group ranged from 2s. 6d. to 7s. 10½d. per head, the rate of mortality was only 10·8 per cent., or half a per cent. less than in the preceding group.

This loose and unscientific generalisation, a method frequently adopted by those opponents of the medicinal use of alcoholic stimuli who are unacquainted with the utter valuelessness of parochial statistics unaccompanied by the particulars of the differing circumstances of each workhouse, sometimes give results apparently confirming the theory that the less the amount of alcohol consumed by the sick, the lower the death-rate. Such a crude and hasty conclusion, I have already shown in these columns to be quite unwarranted by any facts as yet known to us, so far as poor-law experience is concerned. But in the return now under review, even the loose and unscientific generalisation so often attempted, demonstrates that we are not yet in possession of the material on which to establish a general law.

Minute analysis of this return, as the minute analysis of previous returns had done before, clearly shows that we are not justified in arriving at any definite conclusion from the evidence of these figures.

The highest average expenditure for stimulants was at Roscommon, 7s. 10½d. per head, with a death-rate of 14·9 per cent.; while at Ballyshannon there was a mortality more than double, or 30 per cent., with an average expenditure of only a thirteenth of that at Roscommon, or 7d. per head.

At Dunfanaghy the death-rate was 34 per cent., with an average cost of 1s. 4½d.; while at Mount Bellew, with an average cost of 7s. 6d., the death-rate was 11·4 per cent. In other words, the death-rate under between a fifth and a sixth of the amount of stimulants was nearly three times as high as under the more profuse stimulation.

At West Dromore the mortality was 2·1 per cent., with an average cost of 1s. 8d. per head; and 25 per cent. at Longford, with an average cost of 3d. per head; or nearly twelve times as many proportionate deaths under less than a sixth of the stimulation.

Again, with an average cost of one-fifth of a penny per head, at Limavady the death-rate was 21 per cent.; while the mortality was only 5·2 per cent. with an average cost of 5s. 3d. per head at Baltinglass; 7·5 per cent., with an average of 4s. 10½d. at Kells; and 8·8 per cent., with an average of 6s. 4d. per head at Rathdown.

At Armagh, with no stimulants at all, the mortality was 11·8 per cent.; a striking contrast to the mortality of 5·2 per cent. at Baltinglass, with an average alcoholic expenditure of 5s. 3d. per head. With free stimulation, less than half the death-rate with no stimulation at all.

This return, like all other parochial stimulant returns that I have examined, is full of such perplexing and contradictory evidence, as I have now given a few typical examples of. The inference, therefore, is clear that we

have not yet had before us the whole truth. The various unions have little in common. The class of cases admitted to the workhouse is not the same in one locality as in another. The age, state of health on admission, and previous history of each inmate are essential to a fair comparison of results of treatment. So also are the sanitary condition of the building itself, the health, mortality, and diseases prevailing in the neighbourhood of each workhouse, and many other circumstances, none of which has ever been given in these returns. The present return would have been more interesting, and, probably, somewhat more useful, had it, instead of showing only the number of deaths among the total array of sick persons treated, given the number of deaths among the sick who received no stimulants, and the sick who were treated with stimulants.

What may be the actual facts of the case as regards the influence of alcoholic stimulation on the death-rate of patients treated either lavishly or sparingly with alcohol, we have thus no evidence.

So far as the testimony before us goes, though this is evidently without value, and, in fact, misleading, it would seem to be a matter of indifference as to the results. But we know that the presence of intoxicating drinks in any institution is apt to induce disturbance and disorder, and impair the efficiency of the discipline; and it, therefore, cannot be wrong for medical officers to prescribe such troublesome and dangerous remedies only when no other medicinal agent will answer the purpose. May I venture to express a feeling of regret that, while four Irish unions appeared in the Mountmellick return for 1871 as having consumed no alcoholic drink, only one occupied this honourable position in the year 1880.

Clinical Records.

TWO CASES OF MITRAL STENOSIS, WITH TRACINGS.

By C. HANDFIELD JONES, M.D. Cantab., F.R.S.,
Physician to St. Mary's Hospital.

CASE I.—*Presystolic Murmur*—Six years later, well-marked *Tricuspid and Mitral Systolic*—*Death ensued nearly a year later from Cardiac Failure and Intestinal Hemorrhage.*

M. B., æt. 19, a dressmaker, in poor circumstances, admitted August 31st, 1877. She was in hospital in 1871, and also in 1869. When first taken ill she had great pain at heart, and pain in knees and other joints. In 1871 she was a very poor, feeble creature; but in 1877 she had grown into a fine, well-developed, young woman. In 1871 she had precordial pains, short breath, and bronchial catarrh on admission (Nov. 21st.), with a well-marked presystolic murmur. Pericarditis ensued, and she was very ill for some time, but recovered and went out Feb. 23rd. In 1877 she reported that she had been ailing more or less ever since she left hospital, her breath being always short, but her legs not being swollen; she had much cough and expectoration during winters. The dulness area of heart was notably enlarged, and the precordial region bulged. Impulse was felt in the fifth space inside the vertical line. Systolic murmurs were heard at left nipple line, and also at xiphoid (mitral and tricuspid regurgitant), also at mid-sternum, with a normal second sound, and in left neck. One good observer heard also a faint, presystolic murmur; another discredited the idea of mitral stenosis. After treatment (iron, ammonia, and digitalis) she slept well, lying down at full length; pulse was very small and weak, and gave a markedly flat-topped tracing; urine was thick with lithates, non-albuminous. She left the hospital in October, and returned to it on January 8th, 1878. Her breath had got short again in December, and she coughed, and spat up a good deal of blood. She could still lie down well. Pulse 70, irregular and unequal. Cardiac dulness did not transgress median line, extended down to sixth rib,

to left as far as nipple line, and upwards to upper border of fourth rib. Cardiac rhythm irregular. Impulse felt feebly in left second space, distinctly in third, fourth, and fifth; was most marked at and a little beyond nipple line in fifth space. A systolic bruit was heard at mid-sternum, where second sound was weak, also at both sides of neck; at xiphoid a dull, booming bruit was heard, with distinct second sound; at apex in fifth space a first and second sound were heard, the latter weak, but very distinct with binaural stethoscope, the first occasionally attended with a murmur. No distinct thrill to be felt at precordia. Tracing more developed with 84 grammes pressure than with 56; presents a fairly good rise, a long, upward, sloping top, early dirotism, and even rather long fall, occasionally having an abortive systole. There was good entry of air in both lungs posteriorly, only a little rale at lower parts. The heart's sounds were heard in the left back, but no murmur. No anasarca. Veins of neck not full. Urine contained no albumen. Appetite pretty good. Ordered—Diet: port wine, 4 oz.; iron, ammonia, digitalis, t. d.

16th.—Yesterday was attacked with vomiting of bilious matter, and great depression; she became very faint, appeared at one time on the verge of death, but rallied with brandy. She felt faint during the night, but is better to-day; pulse pretty distinct; head aches badly. Omitted medicine. To have brandy and milk.

17th.—Is rallying now, headache much better, much relieved by hot sponge to head. Pil. rhei. co. gr. v., h. s. Subsequently pain came on severely in abdomen, and afterwards in back. Two subcutaneous morphia injections were given without benefit.

20th.—She died on this day.

Post-mortem.—Body well nourished, no anasarca. Apex of heart lay opposite sixth rib, very little fluid in pericardium; edge of liver seen in epigastrium only. But little seen of left lung when sternum and costal cartilages were removed; its edge came down to fifth rib; numerous old adhesions at all parts of pleura. Right lung free, no adhesions, it weighed 20 oz., left 19 oz.; both fairly healthy. Heart weighed nearly 15 oz. Right cavities were normal, contained only a little fluid blood; the valves were healthy. The left auricle was not at all hypertrophied, nor was the left ventricle; both segments of the mitral valve were much thickened, and their edges rendered irregular by sharp projections; the orifice admitted only the top of the little finger; the valve was not funnel-shaped. The aortic orifice was somewhat narrowed, but admitted the index finger easily; the posterior flap was of natural size, but the right and left anterior were shrunken, hardened, and contracted to about two-thirds of their normal dimensions. The spleen weighed 18 oz., was large and very hard from congestion; contained no blocks. Kidneys were of good size; right weighed 8½ oz., left 5½ oz.; they did not peel well, but their surface was not decidedly granular. In the left there was a large block, of deep blackish-red colour; in the right, a smaller similar one, and a deep fissure near one extremity, with cicatrix tissue at its base. The renal tissue in the situation of the blocks was very little altered; the malpighian tufts were pretty normal, the tubes infarcted; but there was no engorgement of the vessels, nor breaking up of the structures. The small intestines were very much discoloured by blood, nearly black externally; and on laying them open their surface was found covered with extravasated blood, forming in some parts a thick layer, and saturating the mucous membrane. The large intestine was in a similar state, but less marked. The liver weighed 46 oz.; was of a pale-yellow colour; firm to the knife and the hand.

Remarks.—The above case is an ordinary instance of mitral stenosis, yet is not devoid of some features of interest. The disappearance of the originally well-marked pre-systolic murmur, and the subsequent development of mitral and tricuspid regurgitants has often been noted, and seems very indicative of the existence of this lesion. The development of a tricuspid murmur is intelligible enough, but it does not seem so easy to understand why a systolic murmur should replace a pre-systolic. Perhaps this may depend on the fibroid change having involved in its advance the columnæ papillares and cordæ tendineæ, and made it less possible for the mitral orifice to be closed. The sharp flap, in which a presystolic murmur often ends, must imply some amount of mobility of the mitral curtains, which at a later period may be lost. The stenosis took its

start most probably in endocarditis occurring during the rheumatic attacks in 1869 and 1871; but the fibroid formation must have gone on gradually increasing during the succeeding years, independently of inflammation, much in the same way as a fibroid tumour. Something besides the inflammation itself must determine whether a valvular endocarditis is to issue in ulceration or its opposite fibroid growth. This can hardly be anything local, especially as there were other indications of fibroid change, as in the liver, spleen, and aortic valves. The fine development of the bodily frame under such unfavourable circumstances as existed is really extraordinary, and shows how much a vigorous tissue-life may effect. The backward pressure caused by the stenosis must have been very considerable: it once produced hæmoptysis, and kept up a certain amount of bronchial catarrh; but the latter was scarcely ever formidable; and it was quite noteworthy how free the lungs remained to the last. Their exemption contrasts strongly with the engorgement of the whole intestinal tract, which occurred shortly before death, and was the chief cause of the fatal asthenia. The simultaneous occurrence of hæmorrhagic infarcta in the kidneys, usually regarded as the result of embolism, suggests the possibility that the intestinal hæmorrhage may have been produced in a similar manner. It is hard, however, to believe that embolism could be so very extensive as this view would require; the intestine is rarely affected in this way, and it seems much more reasonable to regard the obstructed state of the venous current, aggravated by some amount of cirrhosis of the liver, as the chief factor of the congestion and hæmorrhage. Perhaps, also, a catarrhal "croup" contributed to the result, as the severe head-ache implies that some such influence was at work. The tracing of September 1st, 1877, indicates much languor or weakness of the ventricular systole; those of October 17th, 1877, and of January 9th, 1878, show a material improvement in this respect; the pulse, moreover, bore a good pressure. The flat, or house-roof, top of the latter tracing indicates, of course, unduly persistent fulness of the arteries; but it is hard to understand how this state can exist in advanced mitral stenosis, unless, indeed, it is associated with some peculiar change in the capillaries impeding the onward movement of the blood. It should be remarked, however, that such a tracing points much more to stenosis than to simple incompetency, and might aid the diagnosis in obscure cases.

CASE II.—*Morbus Cordis—Death by Hæmoptysis—Mitral Stenosis.*

E. A., æt. 30, married, five children, spare make, light complexion. Had rheumatic fever five years ago, no other special illness. Admitted Aug. 15th, 1877. Breath short last two years, legs and feet swelled a week ago, never before. She cannot lie down. Respiration, 43; pulse, 105, sharp, weakish. Good breathing and resonance in both fronts and backs. Heart's impulse diffused, seen in epigastrium, 3rd, 4th, and 5th spaces, slightly in 6th. A loud mitral systolic murmur is heard at left side and apex, attended with a sharp flap, evidently synchronous with impulse. She has much cough at times, which brings on retching and sickness. Liver dulness begins at 4th space, and extends three finger breadths below the ribs; this region is tender. Urine is high coloured, with sediment of pink lithates, and contains albumen. Veins in arms and in neck were full. Not much swelling of legs. She was ordered ammon. carb., gr. iv.; tr. digitalis, ℞; inf. cascariil, ʒj., t. d.

Sept. 10th.—Is doing well, complains of cough, but can lead singing in the ward, and has good nights. The mitral systolic murmur continues to be well heard in the left side, and a pre-systolic was also thought to be present by one observer. A loud high-pitched systolic murmur, loudest at the end of inspiration, is also distinct at the xiphoid, or a little to its right; a thrill is felt at præcordia. She had meat diet. Strychnia and nitric acid was ordered on Aug. 31, and on Sept. 17 the strychnia was replaced by tr. pruni Virginiani; on the 20th she resumed the ammonia and digitalis. Both the mitral and tricuspid murmurs varied more or less in their intensity. The former was often blended with a shock sound.

She left hospital Nov. 22nd; was re-admitted Jan. 15th, 1878. She had then considerable anasarca of both lower and of left upper extremities, as ascites, orthopnoea, hack ng

cough, with notable hæmoptysis, and frothy mucous expectoration. There was no dulness in the back, air entered both lungs pretty freely, a few râles only were audible. Considerable cardiac impulse was visible to right and left of lower sternum, at epigastrium, and to left of nipple line quite into axilla, maximum intensity of beat about 1 inch to left of nipple. Dulness area increased to left. Rhythm of heart pretty regular; no thrill; no distinct bruit anywhere. Radial pulse of low tension, the artery empties itself between the beats. Liver distinctly enlarged, extending from left hypochondrium to 1 inch below umbilicus; surface slightly jaundiced.

19th.—Hæmoptysis continues; skin of face markedly yellow; sounds of heart pretty normal at apex and mid-sternum.

22nd.—A pretty loud, often high-pitched, murmur is heard at left 5th space in nipple-line, as well as a shock sound, the murmur runs off from the shock sound. At mid-sternum both sounds are pretty normal. At xiphoid a blowing systolic murmur is heard. The heart sounds are heard in the left back, but not the murmur. Loud breathing in left back, weak with crepitations in the right; lower part of right back dull. Much hacking cough. The hæmoptysis increased, and she died on 23rd.

Post-mortem.—Some bloody serum in pericardial space, good deal (800 c.c.) in right pleura. Three or four patches of pulmonary apoplexy in upper lobes and at base of lung, very well defined from the surrounding tissue. One of these patches at the base, an opening of size of a crown was found on surface of lung; one of those in upper lobe was also broken down. In left lung were one or two smaller patches of pulmonary apoplexy not so far advanced as those in right lung. Trachea and bronchi blood-stained internally. Except for the extravasations the lungs were pretty normal. The heart's apex lay opposite the upper border of 6th rib, the organ was quite uncovered by lungs, which was pushed to the left. Right auricle much distended with black clot, as well as the veins opening into it. Right ventricle slightly dilated, full of black clot, its wall was 7 m.m. thick. Both-sets of right valves healthy. Left auricle and ventricle contained black clot, the auricle was not hypertrophied, but its cavity dilated; its wall was 2½ m.m. thick. Left ventricle was not much hypertrophied or dilated; it weighed 11 ozs.; its wall was 11 m.m. thick. The mitral orifice admitted easily a good sized middle finger, but not more; the flaps and cordæ tendineæ were thickened, and the fibrous ring raised into a ridge which surrounded the orifice; the margins of the opening were smooth. The aortic valves were somewhat thickened, but efficient. Other organs not examined.

Remarks.—The pulmonary vessels in this patient must have been less retentive, more weakly organised than those of M. B., as she had copious, even fatal hæmoptysis, while the former, with a much greater amount of mitral narrowing, had but little, and died of hæmorrhage in quite a different situation. This is an instance of what we may often observe how disease finds out the weakest part. *Quæ data porta ruit*, as Sydenham is fond of remarking. A parallel difference in the two cases is the occurrence of notable anasarca in the one with least stenosis, and its absence in the other. In both cases the præstolic murmur in the advanced stage of the malady was absent or inconspicuous, while mitral and tricuspid murmurs were evident. The cardiac impulse in Case II., on her re-admission a week before her death, was very extensive, much more so than the very slight amount of hypertrophy would lead us to expect. You should be prepared for this. It is not rare to find the heart in autopsies much larger than it had appeared to be during life; and conversely the heart may appear during life much larger than it really is. I say this, knowing that the organ may actually, in certain circumstances, be dilated temporarily by yielding of its walls. Much depends on the mode of the cardiac contraction. If it is gradual and quasi-peristaltic (Sanderson) the impulse at the chest-wall may be slight or null, while the blood mass is powerfully impelled. This is often the case in individuals past forty. If, on the other hand, the systole be brief and jerky, little onward movement of the blood may be produced, while the parietal shock may be diffused and forcible, more of the ventricle being applied to the præcordia at each systole than would be normally. A well-sustained steady contraction is far more efficient in driving the blood than a sudden brief jerky. The first may be compared to

the force generated by pebble-powder, the second to that by fine grain. The one is associated with well-controlled and regulated nerve action, the other with paresis of power and paresis of "resistance;" the latter term implying that faculty of a nerve-cell by which it controls the escape of its energy. The one can endure increased exertion, the other is ever on the verge of exhaustion. The subjoined tracing, No. 4, was taken from E. A. during her first stay in hospital. Its tall perfectly vertical primary rise under a small pressure indicates a low degree of arterial tonus attended with a sudden jerky ventricular systole. The predicrotic notch indicates a slight delay in the off-flow from the distended arteries. The true dicrotic notch has no special features, and no special significance. The rhythm is quite regular. The tracing much resembles that of aortic insufficiency, and is quite unlike that of M. B., Case 1., and so affords proof that mitral stenosis does not necessarily, even when of considerable amount, produce any characteristic modification of the pulse-form.

LIST OF TRACINGS.

No. 1.—Taken Sept. 1st, 1877, with pressure 20 grammes, no larger obtained with higher pressures.

No. 2.—Taken Oct. 18th, 1877, with pressure 90 grammes.

No. 3.—Taken Jan. 19th, 1878, with pressure 84 grammes.

No. 4.—Taken Oct. 2nd, 1877, with pressure 10 grammes.

Translations.

THE GERM ORIGIN OF TUBERCLE. *

At a recent meeting of the Paris Academy of Sciences, M. Bouley presented a report of certain highly interesting experiments made by him on this subject. He said:—

In the beginning of this year I made some experiments with the lungs and pulmonary ganglia of a cow killed at the slaughterhouse, but, notwithstanding the low temperature then existing, the animal having been dead twenty-four hours, I obtained in all the flasks, thirteen in number, several different microbes; however, there was one which existed in all, and resembled those which had been delineated as existing in serum, and having been produced by cultivation. On the 1st of March I killed a young sow which had eaten four months before, in two days, the lungs of a cow killed at the slaughterhouse; she had a fully developed tubercle. The lungs contained an enormous quantity of tubercles, all the ganglions were cheesy, especially those of the pharynx, bronchial tubes, and intestines. I collected with all the precautions necessary in such cases, the blood and pulp of the pharyngeal, pulmonary, and intestinal ganglions, and fertilised with them seven bottles containing solution of rabbit, slightly alkaline. The next day the mixture was fermenting, and all the vessels contained one and the same microbes, these results of cultivation, ten in number, have retained their purity. The activity

of multiplication lasts from ten to fifteen days, then, after that time has elapsed the exhausted liquor becomes clear, the microbes fall to the bottom of the vessel, and form a deposit of a pale yellow colour. This deposit is composed exclusively of very small isolated twin granulations, in groups of three to ten together, or in little irregular masses. In the first few days opaque flakes appear which are quite consistent and much resembling the filaments arising in the cultivation of bacteria. When one breathes into a finely drawn tube the greater part of the vapour mounts in it or remains suspended at the extremity, and rest for several days in the clear liquid without becoming diluted. The microbes, during this period, surrounded by an atmosphere of viscid and consistent matter. Examined under the microscope the agglomerated points show portions which are extremely rich in a microbe, which appeared then immovable and spread separately on the entire surface of the preparation. In the liquid parts was observed on the contrary in the isolated twin granulations, or those united in larger numbers, very decided movements, later on the white colour of the liquid became uniform, and at last the microbes fell to the bottom of the vessel. Their opacity is much greater at the end than at the beginning of the cultivation, their diameter is diminished, it is little inferior to that of the microbe in the cholera in fowl, and is only 0^{mm} 0001 to 0^{mm} 0002 in diameter. The first inoculations by cultivation performed on rabbits in the subcutaneous conjunctival tissue were all without result, with the exception of one which was done after a third trial of cultivation. Killed accidentally by a dog on the thirty-third day, this rabbit had some tubercles in the lungs of which the histological characteristics have been proved, but the result was not the same with the cat, when the inoculation took place in the peritoneum. Here again, the animals died of exhaustion after a month's captivity, during which time they were fed entirely on cooked meat. The first cat which died had enormous intestinal ganglions which were cheesy in some parts but at the time the tubercles had not yet become general. I scraped with a scalpel the cup of the ganglion and inoculated the pulp and the serosity into the ears of young rabbits. All the animals thus treated, eight in number, became tuberculous. After two months the infection had become general, the lungs and spleen were full of grey tubercles. The first rabbits which died served for the inoculation of a second series of animals which show us all the symptoms of tuberculosis. Two rabbits of the first series will be preserved until death to prove the nature of their final injuries.

M. H. Bouley presented in the name of M. Toussaint, to the Academy a notice on Parasitism of Tuberculosis, from which we extract the following:—

"The first researches which I made on this subject date from the early part of the year 1880. After having collected in a clean vessel the blood of a tuberculous cow I changed the serum which was formed after coagulation into Pasteur tubes, containing solution of cats, pigs, and rabbits, pure serum was also poured into a tube and placed on a stove. After some days the greater part of these liquids showed in them very small granulations, single, two together, or collected in small masses. I cultivated both mixtures and afterwards inoculated some young cats, these animals do not live in captivity, and all of them died of exhaustion before the time when it would have been possible to determine tuberculosis; five months after having collected the serum I inoculated two other cats, adults, with a Pravaz syringe containing serum which had remained on the stove for some weeks, and had in it spherical granulations of which I have kept a drawing. The two cats were killed forty-seven days after the inoculation,

one of them had a local well defined injury, and a pre-scapular voluminous ganglion, but the lungs did not contain any tubercle. The other had the same local and ganglion injuries, and besides a score of very small tubercles scattered about the two pulmonary lobes. A microscopical examination showed that the affection was principally tuberculous. I only mention this fact to show the duration of the conservation of virus tuberculous. It is certain that this experience cannot suffice to demonstrate the existence of a microbe, the liquid coming directly from the blood."

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

TREATMENT OF ERECTILE TUMOUR BY VACCINATION.—At the last séance of the Académie de Médecine M. Paul read a note on the treatment of erectile tumours by vaccination. The treatment consists in covering the tumour by a layer of vaccine, and then by means of a sharp needle making under the liquid superficial incisions which, in becoming cicatrised, will oppose the extension of the tumour. He presented a child on whom he operated six months ago. In this child the tumour was of considerable proportions, it covered nearly the whole nape of the neck and a quarter of the head. The wound took three months to cicatrise perfectly, and to-day the following results are obtained:—The cicatrix which is uniform over the whole surface is white and devoid of vascularity. It is still raised above the surface of the surrounding skin by the subcutaneous vessels. But after the results of other similar operations the author expects that soon the morbid tissue will become atrophied. M. Blot, commenting on the case, did not believe that this procedure could be as susceptible of being generalised as M. Paul thought. It could not be employed in tumours considerably raised above the skin, nor in those of considerable depth. In flattened tumours and those of a very slight depth, it could be used with success. Again, he believed, that in the method of M. Paul who covered the tumour with the vaccine before making the incisions, there was every chance of the blood in its escape washing away the vaccine. He would prefer to make the incisions first, and when the tumour was well drained of the blood to apply the vaccine. M. Gosselin doubted that this case would succeed, it being evidently a subcutaneous tumour. M. Guerin observed that he had in times gone by, treated, and with success, these kind of erectile tumours by simple subcutaneous scarifications.

TWO OBSERVATIONS ON HYPOGASTRIC LITHOTOMY WITH PREVIOUS DISTENSION OF THE RECTUM.—M. Gosselin read, "Two observations on hypogastric lithotomy with previous distension of the rectum." Two principal motives have hitherto prevented surgeons from adopting hypogastric lithotomy as a general method for extracting stone; the first is, the fear of opening the peritoneum; the second, the difficulty of preventing infiltration of the urine after the operation. In the case of M. Périer (reported by M. Gosselin) the first danger was avoided by placing an air pessary in the rectum, and thus tilted forward the bladder and pushed up the peritoneum, consequently the abdominal wall and the urinary reservoir were able to be incised with impunity. M. Périer was the first to adopt this method in France, but Peterson of Kiel had already practised the same operation in Germany. To avoid the infiltration of urine M. Périer injected an antiseptic solution of winter green into the bladder daily during the twenty days that preceded the operation. After the operation two tubes or siphons were introduced into the bladder one by the wound, and the other by the urethra, in order to facilitate the complete evacuation of the urine. The Académie de Médecine thanked the author for his report and ordered it to be published.

COLD BATH TREATMENT OF TYPHOID FEVER.—Dr. Frantz Glénard is one of the greatest champions in France for the cold bath treatment of typhoid fever. This treatment which two years ago was greatly *à la mode* seems to-day to be fall-

ing into disuse, whilst a certain number of practitioners employ, and not without a certain success, phenic acid in the treatment of this disease, claiming for it an antipyretic effect. M. Glénard cannot reconcile himself to this method for he believes phenic acid to be by no means an antipyretic but simply an anticaloric. The following are his reasons for rejecting it:—It cannot be counted on for lowering surely and sufficiently the febrile temperature; it does not re-establish the regular function of the organism; it does not modify in the slightest degree the typhoid symptoms of the brain, the lungs, heart, or abdominal organs; it prevents no complication. Phenic acid by its absorption causes the accidents attributed to its toxic properties; profuse sweats, albuminuria collapse, pulmonary congestion, visceral degeneration &c. It does not in any way modify the mortality: on the contrary says M. Glénard, in concluding the cold bath realises all these conditions, as has been fully demonstrated by experience.

MALPRACTICE.—The civil tribunal of the Seine gave judgment last week in an action brought by a medical man in Paris against a pharmacist and a client for defamation. The doctor was sent for by his client to see his child who was suffering from croup, and when he arrived and diagnosed the case he prescribed as a vomit a mixture containing sulphate of copper. The prescription was brought to the pharmacist who, on reading it, refused to compound it, saying that the dose of copper was poisonous. The father went to another chemist who immediately began to make it up but the man stopped him and said that it was very fortunate that he did not come there first, as the child would have been poisoned, as another pharmacist had already refused to compound it. The father went out and spread abroad that the doctor had nearly poisoned his child, hence the action. The tribunal in its judgment declared that chemists were in their right in refusing to compound a prescription that they considered to contain an excessive dose of any toxic, and acquitted the chemist of all blame, condemning the doctor to the expenses of the action. The dose of the copper was certified by another medical man to be excessive.

DR. HOUGHARD, of Paris, prescribes with the greatest success, the following pills in the different forms of hæmorrhage, such as metrorrhagia, hæmoptysis, epistaxis, &c. Ergotine, sulphate of quinine, ʒʒ 30 grs.; powdered digitalis, 4 gr.; extract of hyoscyamus, 4 grs. For twenty pills. From five to ten in the day. In this preparation the ergotine and quinine act by contracting the vessels, the digitalis controls the circulation, and the hyoscyamus calms the irritation and pain.

THE SOCIAL SCIENCE CONGRESS, 1881.

On Monday morning last Trinity College, Dublin, opened its halls for the reception of the *savants* of the "National Association for the Promotion of Social Science." In the Education Department the special questions are:—"National (Primary) Education," "Intermediate Education," and the "Higher Education of Women." On the first, papers were contributed by Mr. John Ferguson; on the second, by the Rev. Dr. Molloy, the Rev. Dr. Rice, M.A., Dr. Maurice C. Hime, and Dr. Laffan; and on the third, by Mrs. Byers and Miss Helen Blackburn. The following papers were also contributed:—On "University Education in Ireland," by Mr. Charles Dawson, M.P., and Professor Monck; on the "Inspection of Schools," by Mr. M. Fitzgerald; on the "Progress of National Education in England and Wales," by Mr. Rowland Hamilton; on the "Teaching of Arithmetic," by Professor O'Sullivan; on the "Teaching of the English Language," by Professor Joyce; on the "Study of Physical Science," by Mr. J. S. Doherty; on "Classics," by Mr. Charles H. Keen; on "Twenty Years of the Queen's Institute," by Miss Corlett; and on "The Schools of the Christian Brothers," by Professor Boulger.

In the Health Department the following contributed papers on the special questions:—Mr. H. C. Burdett and Dr. Prospero de Pietra Santa on "Hospitals and the State;" Mr. Michael, Q.C., Dr. Moore, and Dr. Stewart Woodhouse, on the "Compulsory Notification of Infectious Diseases;" the Hon. the Recorder of Dublin, Dr. Cameron, and Mr. Edward Spencer, on "Artisans' Dwellings." The following papers were also contributed:—"The Use of Alcoholic Stimulants in Irish Workhouses," by Dr. MacDowal Cosgrave; the "Progress of Sanitation," by Mr. Edwin Chadwick, C.B.;

"Drunkenness and its Remedy," by Mr. John Pyper; "Sickly Children Dependent on the State," by Mrs. Morgan John O'Connell; and "Notes on the Hygiene of the Dairy and the Dairy Yard," by Mr. James Collins.

In the Economy and Trade Department, amongst other papers were read, "Out-door Relief Systems in England and Ireland," by Mr. Robert H. Jephson; on "the Place of Women in the Administration of the Irish Poor Law," by Miss Isabella Tod; "National Compulsory Insurance," by Mr. Whately Cooke Taylor.

The inaugural meeting of the Congress was held on Monday evening in the Exhibition Building, when an address was delivered by the Lord Chancellor of Ireland, Lord O'Hagan. On Tuesday evening the Statistical Society of Dublin, under the presidency of Dr. Mapother, gave their *conversations* in the rooms of the Royal College of Surgeons, lent by the Council of the College for that purpose. On this evening (Wednesday) the Lord Mayor will entertain the Congress at a *conversation* at the Mansion House, and on Friday the Royal Society will welcome the Association, and at the same time celebrate the 150th anniversary of the foundation of the Society, that event having taken place in the year 1731. In addition to the usual arrangements that are made for such entertainments, it is intended, as far as space will permit, to exhibit the more important development of recent scientific research. Several different systems of electric lighting will be shown in operation, as well as the application of electricity to mechanical purposes, and the so-called storage of force by electrical means. Arrangements are being made for the exhibition of statuary and other objects rendered visible in a dark room by means of luminous paint. The special novelty of the evening, however, will be a telephonic *audition*, for which elaborate preparations are being made with the co-operation of Mr. Gunn, who has kindly consented to afford the Society every facility for carrying out the experiment.

It is intended to employ a large number of telephones in such a manner as to enable the performance of Mr. Irving in the "Cup," at the Gaiety Theatre, to be enjoyed by fifty at a time of the assembled company at the Royal Dublin Society's house.

We learn with satisfaction that the number of visitors is quite as large as could have been expected, and there is every hope that the meeting of the Congress will be a very successful one.

M. SALZER has counted the fibres of the optic nerve. He estimates them at four hundred and thirty-eight thousand. The number of cones in the retina he found to be three millions five hundred thousand.

We understand that Sir George Airy, late Astronomer Royal, is to be awarded the highest possible pension, in consideration of his lengthened and valuable services to science while holding office at the Royal Observatory.

On Friday last the 70th birthday of the Empress of Germany, feasts seemed to have been pretty general throughout the country, and Her Majesty, mindful of the afflicted, provided one for the inmates of hospitals, unions, asylums, and orphanages throughout Berlin and its environs.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 21, Bombay 36, Madras 38, Paris 24, Geneva 22, Brussels 23, Amsterdam 21, Rotterdam 15, The Hague 23, Copenhagen 22, Stockholm 23, Christiania 10, St. Petersburg 41, Berlin 25, Hamburg 22, Dresden 26, Breslau 27, Munich 33, Vienna 21, Prague 23, Buda-Pesth 36, Turin 26, Alexandria 50, New York 33, Brooklyn 28, Philadelphia 22, and Baltimore 31. No returns have been received of Rome, Naples, Venice and Lisbon.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, OCTOBER 5, 1881.

PUNISHMENT IN SCHOOLS.

THE remarks we recently made on the subject of improper punishment of school children have been followed by the appearance in the *Standard* of a number of letters bearing on the whole question in this connection. We distinctly argued the necessity for legislative interference on behalf of the unhappy pupils, who too often fall victims to the misguided zeal of their instructors, or with equally bad results to the vengeful feelings of inferior officials in our larger schools. Parents, as a rule, do not comprehend the risk that is run by their sons and daughters in attending school where slight offences are met with immediate infliction of corporeal chastisement. They fail to connect together the occurrence of later illness and these early inflicted punishments, and in no inconsiderable number of cases does it happen that organic troubles developing at or beyond the period of adolescence are never associated with the scholastic floggings and cuffs to which they are primarily due. Because the developments are, in point of time, long subsequent to the causes producing them, and which are in the majority of cases absolutely forgotten by the victims, therefore it is unusual to date back the lesion to its exciting agency; but rather the attempts made to explain it as originating in some more

recent injury ; or, failing anything to directly account for it, is set down as due to an inexplicable constitutional peculiarity. Fortunately for coming generations of children, the fallacy of ignoring antecedent injuries received during childhood to account for adult diseased conditions, is being more and more widely recognised ; and we cannot doubt but that the more general study of diseases of the nervous system, together with a better appreciation of the influences under which the nervous structures are wont to react, has in a great measure ensured this desirable result. During the period of active growth of the brain, a period, moreover, in which children are most frequently submitted to the tender mercies of younger and less highly educated teachers, it requires but a slight shock to seriously disturb the delicate equilibrium of the organism. We do not need now to be told how easily the brain structure may be influenced by evil agencies at all times, or how especially readily it responds to inappropriate impressions at the age when the whole force of the organ is devoted to increasing its proportions. At such a time a blow, even though it be not a very severe one, delivered on the skull, will suffice to initiate changes that shall by-and-by be productive of the most abnormal consequences, and which may in the intensity of the actions to which they give rise even jeopardise the life of the individual. Every specialist in diseases of the nervous system, can recount case after case in which no feasible explanation of the conditions observed presented itself to the patient's mind, but in which painfully suggestive reminiscences of school boy punishments are readily recalled. How many of these distressing instances we are justified in ascribing to the improper administration of thrashings and beatings about the head, we are probably only just now beginning to understand aright.

It is urged by many teachers that the infliction of corporeal punishment is that alone to which they can trust for maintaining discipline amongst large numbers of scholars. This may, under protest, nevertheless, be admitted ; but granting that it is so, there yet remains the necessity for explaining why punishment may not always take such a form as shall avert any possibility of eventual injury to its recipient. The principle that only the head teacher of each school should be permitted to punish the pupils therein, seems to be freely admitted by all advocates of the system ; but, in spite of this, frequent accounts of severe and undeserved beatings suffered at the hands of inferior teachers, are far too numerous to be overlooked in silence. If discipline must be maintained at the cost of physical torture, the public who entrust their children to the care of schoolmasters and owners, have a right to demand that in circumstances so nearly affecting their interests as those surrounding the safety of their offspring, the responsible head of the school shall alone be answerable, and that any departure from the rule requiring that punishment shall always be received at the hand of the senior teacher, be met with as much severity as any other criminal proceeding. We may assume that for the credit of his school, and the preservation of his own character, in the absence of any higher motives, a master

who wields supreme authority within its limits, will so act as to punish with the least danger of ultimate serious injury ; and further that, as a consequence of recent agitation and explanation on the subject, each one will readily understand in what manner to secure this desirable end. The passing of a law, therefore, making it a penal offence for any other person to punish a pupil, could not fail to be followed by salutary consequences ; and, in this direction, we should feel disposed to look for the improvement that is so sorely needed.

Several of the *Standard's* correspondents have given point to the statements made, on more than one occasion, in these pages ; and in particular, perhaps, we may mention the importance laid by several writers on the injury done to the delicate muscles of young children's hands by the fiendish practice of striking them with pointers, rulers, and the like weapons. It is with a feeling, approaching to a murderous desire, that we have again and again witnessed mere youths, third and fourth masters in large schools, inflict on one shrinking, sensitive child, after another, four, six, or eight blows on the palm of the hand, delivered through a ruler, with all the energy of a devil delighting in torture. A frequent repetition of such treatment—and some miserable children are submitted to it day after day, and week after week, if perchance they are naturally backward and feeble, until the poor little hands are a mass of bruised flesh—and the performance of any labour with them becomes an utter impossibility. Such as these can never, in the future, hope to effect any operations involving delicacy of manipulation ; and that many such unfortunates are, in this way, prevented from pursuing careers to follow which they are fitted in all but manual dexterity, there is too much evidence to prove.

It is, at any rate, an open question how far corporeal punishment is absolutely essential to the maintenance of school discipline. At one time it was fashionable to insist that large numbers of human beings, under whatever circumstances associated together, could be controlled only by fear of bodily pain as a consequence of insubordination. We do not need now to combat so barbarous an idea, and, in most instances, where it used to hold, it has yielded before a wiser and more humane decision. The time will doubtless ere long arrive when it will be the case also with schools ; when it will be a reproach to be charged with a preservation of the old form of punishment ; and already there are not a few institutions where good order is easily preserved by the exercise of moral rather than physical force. It is absurd to urge, as is often done, that a child's nature can be overcome by the fear of suffering alone ; to assert this is to admit the worst possible form of weakness ; and every parent should studiously avoid entrusting his child to the care of an instructor who will give utterance to so palpable a heresy. Children, pre-eminently, are amenable to kindly and genial influences ; and any action that may be taken to enforce the employment of these in all schools, rather than corporeal punishment, will have at all times our hearty and entire support.

THE REFORM OF IRISH MEDICAL EDUCATION BY THE IRISH COLLEGE OF SURGEONS.

SHORTLY after the vote of the Fellows of the Irish College of Surgeons had been given in last May in favour of the New Scheme of Education and Examination proposed by its Council, the election of a new Council took place, and the determination of the Fellows to insist upon an improvement of the existing system was marked on that occasion by the ousting of one of the chief opponents of reform from the Council table. Immediately after the first meeting of the new executive of the College, the new scheme was again taken in hand, and, in spite of the resistance of the anti-reform party, it was finally confirmed and ordered to come into effect with respect to all students commencing their studies from that date forward. But the scheme is, in some important respects, at variance with the old educational bye-laws, and in order that it may be strictly *en regle*, it is necessary, under the provisions of the charters, that the assent of the Home Secretary should be obtained to the abrogation of these bye-laws. This authorisation would be, under ordinary circumstances, a matter of course, firstly, because control now exercised by the General Medical Council has practically superseded that which was vested in the Secretary of State when the charter was made, long before the Medical Council existed—secondly, because it is anomalous and without any precedent in other colleges, that the educational regulations, being called bye-laws, should be fixed and unalterable as they have hitherto been in the Irish College of Surgeons. The Council, therefore, dispatched to the Home Secretary a letter in which they asked that the Educational Regulations should be, so to speak, dis-bye-lawed, and they submitted for his inspection a copy of the new scheme.

Thereupon, the defeated party of anti-reformers thought they saw their opportunity to delay the operation of the proposed improvements and, accordingly, one of the teachers, whose courses of repeated lectures had been curtailed in number and practicalised in character, set on foot a memorial to the Home Secretary begging him *not* to comply with the request of the Council. He had, of course, succeeded in obtaining the signatures of some of the Dublin teachers who are interested in maintaining the existing condition of things at the College; but before either the letter of the Council, or the counter-memorial, could reach the Home Secretary he had left England, and therefore, neither of them have yet been laid before him, nor has any reply been given by him.

So stands the matter at present. It is not at all probable that the Home Secretary will think it his business to revise the decision of the Council and of the Fellows of the College, especially as the new scheme is obviously directed to raise the standard of education of the licentiates of the college, and as any possibility of the public interest being sacrificed is guarded against by the supervision to which the scheme will be submitted by the General Medical Council. Nor is the delay in obtaining the assent of the Home Secretary of the least importance, for—inasmuch as no student need come in under the scheme except those who are now about to commence study—it will be twelve months before the new examination

arrangements need be completed. As for the preliminary examination in general education, the Council can do as it pleases with it, because it is not fixed by any bye-law, and changes in it do not require the assent of the Home Secretary.

As to the movement to prevent the redress of those abuses in connection with Irish medical education which every Fellow of the College and almost every member of the profession in Ireland blushes to acknowledge, we cannot refrain from expressing our chagrin and regret to observe that the common decencies and honesties of medical education, and the interests of the College itself, should be so entirely forgotten in the scramble for lecture fees and apprentice money. If we must appeal to the opponents of improvement in their own interests, we would ask them to consider carefully whether they are not, in grasping at an improbable perpetuation of the dying system of repeated lectures, sham certificates, and credit fees, risking the utter destruction of their own craft? If they were unhappily to succeed in forcing the College of Surgeons to insist upon its licentiates paying cent. per cent. above the market price for their professional qualifications how long would the College continue to exist? When they see that University over which they have no control is ready to give the double qualification for £89, and on one course of lectures in each subject, is it wise, nay, is it even decent, that they should seek to sacrifice the College to the vain attempt to induce parents and students to pay £158 for the empty name of instruction which is neither given to the student, accepted by him, or paid for by his pupil master? The question does not admit of argument. If the short-sighted policy of the Dublin teachers were to prevail they might possibly enjoy a rapidly-decreasing income for three or four years, but eventually the stern logic of competition would reduce them to a tardy surrender, and meanwhile the Irish College of Surgeons would have ceased to exist as a licensing body. May the realisation of so impolitic and disastrous a policy be long distant.

Notes on Current Topics.

A Colonial Cause Celebre.

WE have received from Sydney, Australia, a pamphlet containing full reports of a case investigated there during the present summer, and arising out of the death of a woman on whom Dr. Warren had operated for extra-uterine pregnancy. The details are most instructive, both from the surgical and from the ethical point of view. They well illustrate the possibilities of error in diagnosis in cases of apparently abnormal gestation, the operation having shown that the pregnancy was a normal one, although the sound had previously been admitted into the uterus for a length of three inches. This chiefly induced Dr. Warren to undertake what he terms gastrotomy, but which we are more accustomed to describe as abdominal section. The operation was performed in the presence of a number of medical men, two of whom, moreover, had previously examined the case, while by one of those two it had been transferred to Dr. Warren's care. When the incision into

the tumour had been completed, and the child removed the discovery was made, for the first time, that the womb itself was opened; and following this, for reasons which are carefully explained in the report, the uterus and ovaries were cut away *en masse*. The patient died two days after the operation, and an inquest was held upon the body, the report of which is the work referred to above. On the advisability of the proceeding, on the assumption of an extra-uterine pregnancy, the woman having advanced to within about six weeks of term, a majority of surgeons will probably concur; but even with all the facts given in the published account before them it is doubtful how far a general agreement will obtain as to the necessity for abscission of the uterus and ovaries when the nature of the case was finally established. On this point we do not now offer an opinion; but that which does call for comment is the action of two of the medical men present, who subsequently and directly impugned the conduct of Dr. Warren in a professional sense. By their presence at the operation they surely offered a silent endorsement of the proceedings, and it is to be regretted that their after conduct tended to remove the impression thus conveyed. One of the witnesses at the inquiry, by the way (a Dr. Milford), has enjoyed, according to the evidence he gave, the exceptional opportunities of operating, or assisting in the operation, for "gastrotomy" *eight or nine times*, and he gives it as his conviction that in all such cases as that of Dr. Warren the operation is urgently demanded. The circumstances surrounding the particular case under consideration were evidently most unusual, and it deserves to be noted on account of the peculiar features it presented, and the fatal ease with which error in its diagnosis was possible, and did occur, in spite of the most careful and skilful examination.

Headaches.

THE approach of the winter season will, with a large number of people, be inaugural of a recurrent headache, for which they are unable to account at all satisfactorily, but which experience has taught them to expect as surely as fires and "snugness" are rendered necessary to personal comfort. It would be well if all such sufferers were to understand the *rationale* of the complaint that periodically attacks them, and be wise in time to ward off the return of their old malady. In every case where the headache is not dependent on some organic disturbance, and when it is felt only during the colder months of the year, especially in large towns, it is undoubtedly due to the vitiated atmosphere of rooms lighted by gas, and rendered "snug" by close-drawn curtains and draught-excluding doors, while a brilliant fire is maintained for heating purposes. This latter is, indeed, the only preventive under the circumstances, of an absolutely poisonous condition of the air, which is very seriously contaminated wherever a gas-light is employed for illumination. Careful observation of the effects gradually produced by prolonged continuance in such an apartment, will reveal the fact that a feeling of oppression, becoming gradually more intense, steals over one; and in an increased degree accordingly as the number of occupants of the room is added to. The atmosphere becomes thus heavily laden with carbonic acid, the products of combustion of the gas and of the human tissues;

failing any free ventilation this rapidly accumulates, an insignificant amount alone finding exit by the chimney, and acting on the nervous system of those using the room, induces cerebral congestion that results in serious disturbances, which are relieved only after a more or less painful period of indisposition. The remedy for the evil is in efficient and constant ventilation, a necessity that every householder should see is secured in all the rooms of his dwelling before they are transformed into winter habitations.

Platelayers' Risks.

AN unfortunate occurrence, by which two lives were sacrificed, took place last week at the Crystal Palace Station of the London, Brighton, and South Coast Railway, and which shows the need for much more consideration on the part of railway companies to their *employées*. The victims in this accident were platelayers, engaged in work in the tunnel just without the station, and who, while standing clear of an outgoing train, were knocked down, and one killed, the other fatally injured, by another train which was invisible through the smoke left by the first. It was shown, in evidence, at the inquest that many tunnels on railways are so constructed as to leave no means of safety to labourers in them when overtaken by two trains at the same moment, except they prostrate themselves in the space between the lines, and thereby expose themselves to the risk of injury by fire and steam from passing engines. In the particular tunnel referred to, the ventilation shafts have been filled up, so that no escape for imprisoned smoke and steam, except at either end, exists; and, in addition, there are no "manholes," or side spaces, in the walls to which workmen can hasten for shelter. The lot of railway labourers is by no means enviable at the best, and the hardships they endure need no intensifying by the certain risk attending their employment in unprotected situations. Moreover, without adequate ventilation tunnel work must be highly injurious to the general health; and in every way there is ample reason for demanding extensive improvements in the construction of these darker portions of the great railway systems.

Artisans' Dwellings in Dublin.

AT the recent general meeting of the Dublin Artisans' Dwellings Company, the chairman stated that during the half year the company had received in rents more than they had received any previous half year. Their expenses, however, were somewhat larger; accounted for by the severe frost of the winter. They recommended a dividend of 4 per cent. The rental this half year showed a substantial increase as compared with the half year just closed. The fifty-six houses had recently been built, and although it was only the 16th of August they erected the last of those houses, they were all let to respectable tenants. The sanitary condition of the houses, he was happy to say, continued most satisfactory. On the 30th of June they had 1,428 inhabitants in their houses. The deaths for the half year were but 11, and of these 5 were children under 5 years of age. Thus, the death rate was but 15 per 1,000, while the death rate in the city at large was 33 per 1,000.

Army and Indian Medical Items.

THE *United Service Gazette* says:—The officers of the Army Medical Department are looking forward with hopeful eagerness to the reign of a new director general. Dr. Crawford's last tenure of office 'at Whitehall Yard was a halcyon period of "a fair field and no favour," and it is quite time that the department had a chief with sufficient energy and firmness of character both to reign and to govern. By some extraordinary apathy—to give it a mild name—on the part of the professional heads, the arrangement of the foreign service roster and of appointments at home has been allowed to get into the hands of a civilian clerk, who is naturally looked upon as the real master of the department. It might be reasonably thought that this work is rather the province of one of the numerous well paid officers of standing who are at present engaged in examining returns and compiling statistics. At present there is a general feeling that more might have been done to carry out the promises held out some years ago of something like an equality in the periods of home and foreign service. As it is, officers after five years in the tropics, are barely secure of two years at home.

We regret to have to state that by late advices from the West Indies fevers of a very malignant type are prevailing more or less throughout the islands—Demerara, Trinidad, and Barbadoes being especially the sufferers. In the latter island the colonel of engineers and some of his family; a surgeon-major and his wife; a commissariat officer, and many of the troops, together with the wife of His Excellency the Governor, have of late fallen victims to yellow fever. From August 1 to 26 there were 186 interments in the Westbury Cemetery. Captain Lawless, Army Pay Department, died suddenly at Barbadoes from apoplexy.

We learn that the draft of a proposed memorial to the Queen in Council, amending the temporary loss of full and full half pay incurred by certain naval medical officers under the Order in Council of April 1st last, has been submitted by the Admiralty to the Treasury.

Staff-Surgeon Edward Mahon, R.N., whose special promotion for services during the Transvaal war was notified in Friday's *Gazette*, has, we hear, been recommended to the War Office by the Admiralty for decoration with the Victoria Cross for the great gallantry he displayed at Mejuba Hill.

Thames and Lea Pollution.

OUR statement of last week as to constantly recurring dangerous pollution of the Thames by the rural population living on its banks receives a remarkable confirmation. On Thursday last, at Henley-on-Thames Police Court, the Conservators of the Thames summoned the Rural Sanitary Authority of Henley for continuing to pollute the Thames by allowing the drainage of Caversham to enter the river. The defence set up was that the local authority had done its utmost to prevent pollution, and utterly failed. Mr. Wimper, the Analyst of the Conservators, proved that the water taken from the Thames near one of the principal outlets was concentrated sewage. As to the "purity and wholesomeness of the water of the river Lea, the evidence to the contrary is of the most trenchant character. We

need only refer to one fact with regard to it, and we do so because it has been commented upon as a public scandal. It appears that the vast population of the East-end of London constantly resort to it as "a pleasant bathing-place;" but it so happens that in consequence accidents from drowning are constantly occurring. It cannot be otherwise, for at one part of the river where a tributary stream flows into it—the Horse Shoe—so rapid is the current that the moment a bather ventures from the shore he gets into deep water he is almost certain to be drowned. It may be days before the body is recovered. The fact is, as Dr. Frankland states in his last report to the Local Government Board, that the water of the Thames and Lea is year by year becoming more contaminated and unfit for use as a potable water.

Hop Bitters.

Vanity Fair has taken up its parable against patent medicines. The author has found in a wholesale price list over 2,000 patent medicines named and priced. After counting the advertisements of medicines which appeared in all the Metropolitan papers in one week, and calculating from some knowledge of journalistic management, it is estimated that some £3,500 per week is spent in London alone for advertisements of nostrums. By another calculation it is reckoned that at least a further £3,800 is spent weekly in the provincial press for a similar purpose. To this has to be added the countless placards, the millions of bills, and the infinite variety of more or less artistic skill which is exercised on various forms of puffing, for all of which the patient public has to pay.

Hop bitters is then analysed and discussed:—

Tincture of hops, $\frac{1}{2}$ fl. oz.; tincture of buchu, 3 drachms; tincture of senega, 3 drachms; podophyllin, 1 grain, dissolved in spirits of wine, $\frac{1}{2}$ oz.; tincture of cochineal, 20 drops; and distilled water up to 16 oz. The cost of these ingredients, based on prices quoted, it is said, in Messrs. Goodall's private list, amounts to about 5½d. The selling price of the mixture is 4s. 6d.

The Veterinary Surgeons Act.

THIS Act, which passed on one of the last days of the session of 1881, makes it illegal for an unregistered person to assume the style or title of veterinary surgeon, or any name, title, addition, or description stating that he is a veterinary surgeon or a practitioner of veterinary surgery.

The Royal College of Veterinary Surgeons is created the examining body. The first persons eligible for registration are those who possess some recognised diploma. All British practitioners must be members of the Royal College of Veterinary Surgeons. Persons who possess a foreign or colonial diploma entitling them to practise in the colony or country where it was granted, are entitled to registration under certain conditions. The sections which impose a penalty for the use of the title of "veterinary surgeon" do not come into force till January, 1884, though a penalty of £20 is imposed at once on any unregistered person who may hold himself out to be registered.

The Act does not forbid, or in any way hinder, veterinary practice. It protects the title "veterinary surgeon," and makes it impossible for unregistered persons to recover fees

for advice; but it does not prevent practice for cash, nor the recovery of payment for goods supplied.

New Facts concerning Rabies.

THE *Veterinary Journal* for October reports that a contribution to our knowledge of this disorder has been recently made by M. Galtier, after a series of experiments. These were made principally on rabbits, and the most important of the conclusions which he draws therefrom is, that the saliva of a mad dog, obtained from the living animal and kept in water, continues virulent five, fourteen, and even twenty-four hours afterwards. This fact has consequences which everybody should be aware of. Thus it seems that the water of a vessel in which a mad dog may have dropped some of its saliva in attempting to drink should be considered virulent at least during twenty-four hours; and next, that as the saliva of a mad dog which has succumbed to the malady or has been killed does not lose its properties through mere cooling of the body, it is important, in examining the cavities of the mouth and throat after death, to guard against the possible danger of inoculation. M. Galtier tested rabbits with regard to rabies, and found it transmissible to them from the dog; also, the rabbits' rabies from them to animals of the same species. The chief symptoms are paralysis and convulsions. The animal may live from a few hours to four days after the disease has declared itself. It is notable that the period of incubation is much shorter in the rabbit than in other animals, and this makes the rabbit a useful reagent for determining the virulence of a particular liquid. M. Galtier found salicylic acid, injected daily under the skin, powerless to prevent the development of the disorder in rabbits.

Registration of Medical Practitioners.

IN our Students' Number it was inadvertently stated that the fee for a first entry of a medical practitioner in the Medical Register is £6. This statement is incorrect, the amount being, as it always has been, £5.

Treatment of Sprains.

DR. BRINTON (*Philadelphia Reporter*) orders the injured limb to be placed in hot water, and boiling water added slowly until the highest endurable temperature is attained. The limb should be retained in the water fifteen or twenty minutes, when the pain will be found to have disappeared in most cases.

The Openings.

ON Saturday last the London and St. Thomas's Hospitals were opened for the winter session, the first informally, the latter by an address from Dr. Bernays. On Monday all the remaining schools commenced active work; at Charing Cross, an afternoon *soirée*, held in the new school buildings, was largely attended, and apparently afforded enjoyment to all present. At other places pleasant *réunions* were also held.

THE stamp duty on patent medicines for the year ending March 31st last amounted to £139,762 18s. 10½d.

The Profits of Zoedone.

THE first annual meeting of the Zoedone company was recently held in London, Mr. Hoare presiding. The report stated that the whole expenses and charges amounted to £6,208, which left a total net profit of £45,024 (!!!) out of which an interim dividend at the rate of 25 per cent. per annum was paid last December, and a further similar dividend was now recommended. Of the balance of the net profit, £15,000 was carried to the reserve fund, leaving £5,024 to be carried forward.

Chinese Malachite.

LAST month a "cheap Jack" was charged at Warwick with having obtained 1s. by false pretences. The defendant had been in the habit of attending markets to sell bottles of medicine which he called "Chinese malachite." He would collect an audience and then expatiate on the stores of learning and genius hidden in the recesses of Chinese lore, and then began to unpack a tea-chest containing bottles of his malachite, which he professed to have received from his agents in China. It was a specific, he said, for rheumatism, shortness of breath, and various other maladies. It could, he added, be purchased of all chemists at 10s. 6d. a bottle; but to show how they imposed on the public, he would sell it at 1s. a bottle. A person who had been assistant with him testified that the prisoner made the malachite himself of "Chili pods, aniseed, cloves, cinnamon, cayenne pepper, and black sugar. The cost would be about a farthing a bottle, and prisoner would sometimes sell 1,200 or 1,300 bottles." For the defence it was contended that the accused was entitled to call his medicine "Chinese malachite," the same as other concoctors of medicines gave them distinctive names. The Bench at once dismissed the case.

ACCORDING to the *Pharmaceutische Zeitung*, July 29, of 850 analyses made in June of food and beverages sold in Nice, no less than 559 were found to be seriously adulterated.

DURING the meeting of the International Medical Congress in London some English and foreign doctors were discussing the style of apparel most suitable for the occasion of one of the conversations or receptions. Dr. Charcot, of Paris, quietly observed—"As for me, I shall go in my night-dress."

DR. W. H. STONE, of St. Thomas's Hospital, has accepted the post of Lecturer on Musical Acoustics at Trinity College, London, and has placed his collection of acoustical apparatus at the disposal of the College; to which loan Mr. Spottiswoode has added his celebrated "Siren," by Koenig.

THE Metropolitan Hospital Sunday Fund received its first legacy about a week ago. The executors of a benevolent gentleman, who stipulated that his name should remain unknown—indeed, made it a condition as to the acceptance of the bequest—paid over £300, free of duty, to the Council of the Fund, under the initials only, T. J. M.

DR. BEARD says that one of the pleasantest memories of his course at medical college is the fact that he did not attend one lecture in twelve.

THE steady decline of small pox in London was further shown by the reports presented at the meeting of the Metropolitan Asylums Board on Saturday last. The fresh cases admitted in all the fever hospitals for the month were 332, discharged 311, remaining under treatment 440, died 56, as compared with 406, 479, 559, and 80, showing a decrease of 81. The number of beds now available is 580.

SPEAKING about the character of the attendants of a sick person, Dr. J. M. Fothergill says:—"A pious widow, with dyspepsia and strong religious convictions, is a ghoul when illness is about. She sucks the life out of an invalid like a moral vampire. As life ebbs she is sustained, and when the invalid has passed the portals of another world she goes away edified, strengthened and encouraged in her murderous mission, fully prepared to extinguish the lives of any number of relatives if ill-luck should prostrate them upon the sick bed."

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population, were—Bradford 15, Leeds 15, Birmingham 15, Bristol 15, Brighton 15, Salford 15, Sunderland 15, Portsmouth 16, Sheffield 17, Plymouth 17, London 17, Oldham 18, Glasgow 19, Edinburgh 20, Nottingham 20, Norwich 20, Leicester 20, Dublin 22, Newcastle-on-Tyne 22, Wolverhampton 22, Liverpool 23, Hull 24, Manchester 25.

THE British Pharmaceutical Conference held its sessions at York on the last two days of August, under the presidency of Mr. Reynolds, of Leeds. Over 130 visitors attended the meeting, making with the attendance from York itself 166, which was within 10 of the largest number on record. A full programme of good pharmaceutical papers was presented, and on the day following the sessions an excursion to Ripon and Fountains Abbey wound up the event. Professor Attfield was elected president for the next Conference, which is to be held at Southampton.

FROM diseases of the zymotic type last week in the large towns scarlet fever showed the largest proportional fatality in Hull, Nottingham, and Bradford; no fewer than 197 fatal cases of this disease have been recorded in Hull during the past twelve weeks, of which 22 were registered last week. The 33 deaths from diphtheria included 14 in London, 10 in Glasgow, 5 in Portsmouth, and 2 in Birmingham. Fever, principally enteric, showed the highest death-rate in Liverpool, Glasgow, and Portsmouth. The fatality of diarrhoea was considerably below the average for the season. Small-pox caused 27 more deaths in London and its outer ring of suburban districts, one in Oldham, and one in Newcastle-upon-Tyne; while no death from this disease was recorded in any of the other large towns.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE EXAMINATION OF STUDENTS AT THE SCOTCH UNIVERSITIES.—The Royal Commission on Medical Education will have to consider the present system under which students are examined at the Universities with the object of making some alteration and improvement in a system which has nothing to be said in its favour and against which a great deal may be said. The present system, under which the teacher is the examiner of the taught, has two grave defects: it begets narrowness on the part of the student and a tendency to use undue severity on the part of the teachers towards candidates who do not attend their classes. Professors are not devoid of human frailties, and, as their incomes depend upon their classes, allowance must be made for the same. In many cases, also, the selection of a professor does not always depend upon unusual fitness for his work, his election as often as otherwise depending upon his marriage relations, &c. Under these circumstances it is unfair to the student to require his attendance at the class of such an instructor, and in all cases where the teacher is thus deficient the student pays for food on which he starves. Again, where the teacher is also the examiner there is a great tendency for the student to depend simply on the notes taken in the class room, and confining himself to these he becomes narrow in his views and injuriously cramped. In Edinburgh and Glasgow, where there are vigorous and thriving extra-mural schools, the weak points of the system we have been condemning are only too apparent. The value of the additional examiners appointed by the Universities is more apparent than real, and students cannot divest themselves of the impression that the professor is still the actual examiner.

SANITARY SCIENCE IN ABERDEEN.—A Town Councillor in Aberdeen has discovered a ready method of dealing with tenants who use their water closets for the removal of old rags, heads of cod fish, and other household rubbish; he closes up the closet and leaves his tenants to get the best accommodation they can elsewhere. It appears that owing to a stoppage in a soil pipe, a partition wall was somewhat injured, and to prevent a recurrence of the nuisance, the councillor came to the sage conclusion that a water closet was a superfluity, and therefore, closed it up without making the slightest provision for the removal of the household excreta. A medical officer of health will find it no easy matter to deal with a town council some of the members of which possess such unenlightened views as to the sanitary requirements of the people.

DREADFUL ASSAULT BY A LUNATIC.—On the 29th ult. a very melancholy occurrence took place at the Lunatic Asylum at Merryflats. On Tuesday evening about twenty workmen, patients, were coming home from work under two attendants. One of the lunatics was wheeling a barrow in which there was a spade. He put down the barrow, and the attendant, a fine young man, of 25 years of age, named Angus, asked him to take it up again. Without a word of warning the lunatic picked up the spade, and whirling it round, smashed the base of the skull of the attendant in a most frightful manner. Dr. Dunlop was soon in attendance, and every thing that medical skill could do was done to save the life of the young man, but from the first the case was hopeless. The lunatic is now in confinement pending magisterial inquiry.

UNIVERSITY OF ABERDEEN.—It is understood that the

Conservative Students of this University intend adopting Sir James Paget as their candidate for the Lord Rectorship, in opposition to Dr. Bain.

DEATH-RATE OF GLASGOW.—The Glasgow death-rate for week ending with Saturday the 24th ult., was 19 per 1,000 of the population as compared with 21 of the preceding week. For the corresponding week in 1880 the rate was 20 per 1,000, and for the same periods in 1879, and 1878, 17 and 22 respectively.

PECULIAR GUN ACCIDENT IN DUMFRIES.—A somewhat serious gun accident occurred to Dr. Alexander Thomson, Dumfries, on the 28th ult., in the shop of Mr. McCall, gun-maker. Mr. McCall was explaining to the doctor the action of a saloon rifle, and, for the purpose of illustration, put a cartridge into the weapon. In doing so, his thumb accidentally caught the hammer, which came down and caused the charge to go off. The bullet passed through Dr. Thomson's right leg below the knee, causing a great flow of blood.

THE RECTORSHIP OF ABERDEEN UNIVERSITY.—The contest for this office is likely to be a keen one. It will be remembered that at the last election of an Assessor to the University, Dr. Bain, the late Professor of Logic, was beaten by the clerical influence brought to bear against him. His opinions are a little too advanced for a certain sect of the clergy in Aberdeen, who are not, however, peculiar in the narrowness of their views from the rest of their caste elsewhere. As Lord Rector Dr. Bain will be able to command two *votes* in the Councils of the University, and it therefore becomes the duty of all lovers of freedom and progress to support Dr. Bain. The election rests with the students, and it is to be hoped that the medical portion of the University will not be behind hand in supporting Dr. Bain. The Conservative candidate is Lord Cranbrook.

DEAN STANLEY AND ST. ANDREWS UNIVERSITY.—The late Dean of Westminster has bequeathed to the University of St. Andrews his interesting collection of curiosities and historical relics. These include souvenirs of the desert of Sinai and of Palestine, gathered by the Dean himself during his Eastern tour, as well as many memorials connected with the Eastern Church, and also with famous scenes in mediæval and modern history. The executors of the late Dean have expressed a wish that it should be preserved in a separate cabinet within the University Museum.

THE LATE MR. A. B. STIRLING.—The anatomical department of the University of Edinburgh has lost a most valuable assistant, and science a most devoted follower, by the death of Mr. A. B. Stirling. Mr. Stirling belonged to a type of men, common in Scotland, who, by their energy, perseverance, and strength of character, raise themselves from low to high positions. The son of a shoemaker, Mr. Stirling was by turns a shoemaker, gamekeeper, and chief assistant in the Anatomical Museum in the University of Edinburgh. He was a devoted naturalist, and his knowledge of the habits and structure of fish, more especially of the salmonidæ, led him to take a keen interest in the "fungus disease" affecting salmon, which has decimated the Tweed and other of our rivers; and he communicated to the Royal Society of Edinburgh a series of memoirs on this disease, which contain the fullest and most exact information on its pathology that has yet been published. The funeral took place at Warriston Cemetery on Saturday last. Had the University been in session at present there would doubtless have been a large attendance of students, by whom the deceased was held in high esteem, but, as it was, the company was confined to the

relatives of Mr. Stirling, such of the Professors as were in town, and a number of medical gentlemen.

THE OLD INFIRMARY BUILDINGS, EDINBURGH.—The Sub-Committee of the Treasurer's Committee of the Edinburgh Town Council, charged with the arrangements for the conversion of the portion of the Old Royal Infirmary buildings purchased by the Corporation for the purpose of a fever hospital, had a meeting last week, and instructed Mr. Morham, city superintendent, to proceed with the preparation of the necessary plans. The Burgh Engineer is to examine and report as to the drainage; and Dr. Littlejohn to report as to the allocation of the wards for different kinds of infectious diseases.

Literary Notes and Gossip.

PROFESSOR HUXLEY promises a new volume to be entitled "Science and Culture and Other Essays," which Messrs. Macmillan and Co. will publish, the same firm also announcing "A Course of Instruction in Zootomy" (Vertebrata), by Professor T. Jeffrey Parker, B.Sc., of Otago University; and vol. iii. of Professors Roscoe and Schorlemann's "Chemistry," to include the hydro-carbon compounds.

The new Savoy theatre will be the first in this country to utilise the electric light for interior illumination, and Mr. Swan's improved lamps are admirably adapted to ensure the success of the trial; 300 of these will be employed on the stage and in the auditorium, and by a friendly arrangement with Messrs. Siemens' Bros., the power will, in future, be supplied by their apparatus. The hygienic advantages of substituting the electric light for gas, need no enforcing.

ACCORDING to the researches of Dr. John S. Billings, of Washington, there are now in existence over 120,000 volumes of medical literature, and double that number of pamphlets, with a prospective addition of 1,500 volumes and 2,500 pamphlets every year. France, although far below other countries in the number of medical men, has nevertheless the largest number of medical writers by far, in proportion nearly all her physicians contributing more or less to medical literature.

A FRENCH translation is announced of the researches in Acoustics, conducted by Dr. Rudolph König, and published from time to time during the last fifteen years, in the *Annalen der Physik*. The whole of the papers are to be collected into a single volume, and illustrations of the newly-invented apparatus, designed to illustrate the results of experiments, are to be included in the work, the appearance of which will mark an era in the study of sound as a science.

THE Cartwright prize, awarded this year for the first time, has been made in favour of Dr. Frederik R. Henry, of Philadelphia, the essay, on account of which he was thus distinguished, being entitled "Observations with the Hæmacytometer upon the Globular Composition of Blood and Milk." The results of an extended series of observations conducted with the view of determining the corpuscular values of these fluids must be valuable to many persons, and it is to be hoped the essay may be accessible to the general profession.

THE presence of a princely chairman at a Scientific Congress is an event sufficiently unusual to deserve passing notice at least, and we may therefore express the pleasure with which the whole medical profession accepts the hearty sympathy shown by Duke Theodor, of Bavaria, in all pertaining to the interests of the calling he has embraced. His most recent public act as a medical man, that of presiding over the Hygienic Congress at Vienna, is another only of the many graceful acts already performed by him in his professional capacity. His sound surgery, and knowledge of medical science, make him a most fitting occupant of the post just held by him.

A LITERARY light, of some little eminence, has just passed away in the person of Mr. John Postgate, F.R.C.S., professor of medical jurisprudence in Queen's College, Birmingham. Sanita-

tion and adulteration were his principal themes, and of these he never seemed to tire; one by one pamphlets issued from his pen, as rapidly as tales from a professional novelist. Yet they had their day, and the author of them, who could lay claim to being the originator of the movement against adulteration, had the satisfaction of finally seeing his efforts rewarded by the passing of the "Adulteration of Food and Drugs Act."

Of books published during the past month in medicine and collateral sciences, may be mentioned Dr. Wilson's "Treatise on the Continued Fevers" (this volume completes the series for the year of Wood's "Library of Standard Authors," reproduced in this country by Messrs. Sampson Low and Co.). Dr. Hartmann's "Deafmutism," translated by Dr. Patterson Cassells, of Glasgow, and published by Messrs. Baillière, Tindall, and Cox. A new edition of Smith's "Principles and Practice of Operative Surgery" (Low and Co.). The General Index to Ziemssen's "Cyclopaedia of Medicine" (Low and Co.). Gower's "Epilepsy and other Chronic Convulsive Diseases" (Churchill). Warrington Howard's Treatise on "Orthopedic Surgery" (Longmans). Van Buren's "Diseases of the Rectum" (Lewis). S. Ricker's "Text-book of Organic Chemistry" (Kegan Paul). A new edition of Heath's "Practical Anatomy" (Churchill's). A fifth edition of Mayne's "Medical Vocabulary," and a new edition of Charteris's "Medicine."

The publishing season has not dawned on the profession with many promises of new books:—In anatomy, a new edition of Holden, and a new work by Mr. Mears, of the University of Durham Medical School, on "Schematic Anatomy," are announced. In botany, new editions of Bentley and Semple. In chemistry, a new edition of Semple's aids. In dentistry, a new edition of Tomes' manual. In physiology, a third edition of Rutherford's outlines. In surgery, an International Encyclopaedia, in six volumes, to be published quarterly by Messrs. Wood and Co., of New York, Philadelphia, and reproduced in this country by Messrs. Macmillan. In midwifery and diseases of women, a fourth edition of Meadows' Manual, and Dr. Palfrey's aids; a second edition of Berkeley Hill's Syphilis, and a small book on Cholera, by Octavius Sturges. The other subjects are altogether unrepresented—so meagre a record has not probably been seen for many years past.

A REMARKABLE feature of the forthcoming publishers' season will be the large number of geographical and other works of travel, Messrs. Sampson Low and Co. and Messrs. Macmillan having together announced nearly a dozen volumes in this particular branch of literature. Many of these will possess high interest for medical readers since the observations contained in them are likely in frequent instances to reflect the hygienic conditions under which the various peoples are living, and contain also some indications of prevalent diseases. Among the more notable works being announced we would mention Lieutenant A. Hoogstraal's "Voyage of the Vega," a popular account of Professor Nordenfjöld's expedition; and "Upolu," a description of the chief island of the Samoan group, by H. B. Sterndale; both to be published by Messrs. Sampson Low and Co.

THE literary cravings of medical students must be indeed great, inasmuch as the *Student's Journal and Hospital Gazette* has been found to be insufficient to meet the entire demand, and a rival is threatened in the shape of a penny weekly, to be called, *The Medical News and Collegiate Herald*. The new caterer for students' mental food, and students' pennies, is to make his bow on October 23th, and we are somewhat curious to see how much in quantity and quality of the delectable can be furnished at the price. True, we have our penny dailies, rich in both these essentials, but the field here is cosmopolitan, and the support accorded commensurate therewith. Has the editor of the coming bantling fairly weighed his chances, and his possible emoluments at a penny per head, even assuming every medical student reads what he provides? We heartily wish the new venture success, although scarcely anticipating it.

New Books and new Editions received for review since the publication of our last list, Aug. 24:—"Army Medical Blue-book for 1879." "Treatise on the Continued Fevers." By J. C. Wilson, M.D. "Principles and Practice of Operative Surgery." By Stephen Smith, M.D. "Hartmann on Deaf-mutism." Translated by J. Patterson Cassells, M.D. "Practical Botany." By D. Houston. "Chemical Vade-Mecum."

By G. Jones, F.C.S. "General Index to Ziemssen's Cyclopaedia of the Practice of Medicine." "Davos Platz." By Alfred Wise, M.D. "Notes on Midwifery." By J. Reynolds, M.R.C.S. "The Climate of the Undercliff." By J. L. Whitehead, M.D. "Lectures on Diseases of the Rectum." By W. H. Van Buren, M.D. "What to do in Cases of Poisoning." By W. Murrell, M.D. "Health Resorts for Tropical Invalids." By W. J. Moore, L.R.C.P. Ed. "Treatise on Orthopaedic Surgery." By J. W. Haward, F.R.C.S. "Epilepsy and other Chronic Convulsive Diseases." By W. R. Gowers, M.D.

Obituary.

MR. J. POSTGATE, F.R.C.S., OF BIRMINGHAM.

THE sudden death of this gentleman immediately on his return from Germany, whither he had gone for his annual tour, will recal to many minds the services he rendered some few years since to the country by the energetic and laborious crusade against the adulteration of food, which he carried on at great personal sacrifice for many years, and which ultimately resulted in the passing of the Act of Parliament for its suppression. Mr. Postgate, like a good many others had gone abroad for health, but instead of that rest so necessary after arduous duties, both physical and mental, which he would have more surely obtained in his own land, he was tempted into the varied seductions of foreign travel, where quiet is secondary and sightseeing paramount, and he returned last week, enfeebled thereby, to die in the London Hospital, at the comparatively early age of sixty. Deceased, although a resident of Birmingham, was well-known and much respected in far wider circles. His educational life was spent in London, Leeds, and Paris. He became a Member of the English College of Surgeons in 1844, and a Fellow by examination in 1854. He was a Member of the Paris Academy of Medicine, and Professor of Medical Jurisprudence in Queen's College, Birmingham, where his loss is keenly felt. But as the originator of the public movement against the adulteration of food and drugs, his name will be best remembered and held in London.

DR. ALEXANDRE CARTE, OF DUBLIN.

By the lamented death of Dr. Alexander Carte, Director of the Dublin Science and Art Museums, one of the chief representatives of comparative anatomy and zoology in Ireland has been taken away. Dr. Carte made his scientific name as curator of the museums of the Irish College of Surgeons, which office he resigned in 1851, on his appointment to that which he held at his death. He was a Fellow of the College and an M.D. of Dublin University, and he received his surgical qualification in 1833. His distinguished position in his own special department of science was recognised by his election as a Fellow of the Linnean Society and of the Academy of Sciences of Philadelphia, and he has left behind him a name and a memory widely respected by the profession in Ireland.

DR. JOSEPH BROWN, OF KINROSS ASYLUM.

A MELANCHOLY accident, with fatal result, occurred to Dr. Joseph Brown, on Wednesday last. Deceased was stepping into his carriage, in which three ladies were seated, when the horse suddenly started, dragging the doctor along on the footstep for about 150 yards. In endeavouring to free himself by jumping off, he fell in front of the wheels, which passed over his body, causing such severe internal injuries that he died within an hour thereafter. Dr. Mitchell, his assistant, and Dr. White-law, Cupar, were speedily in attendance, but their services were unavailing. The carriage was stopped near the Kinross Asylum, of which Dr. Brown was the medical superintendent, the ladies being uninjured.

The deceased gentleman studied at the Edinburgh

University, taking the M.B.C.M. degree in 1871, and F.R.C.P.E. in 1876. He was some time assistant at the Saughton Hall Asylum, and afterwards was senior assistant at Morningside Asylum, Edinburgh. Four years ago he was appointed medical superintendent at the Fife and Kinross Asylum in succession to Dr. Fraser, and was highly esteemed by the board of management for the efficient manner in which he discharged his duties, and by those members of the profession with whom he came in contact, as an upright and able physician with a brilliant career before him in that particular branch he had mapped out for himself.

The deceased, who was only thirty-three years of age, was the only son of the late Dr. Brown, Wooler, and the only near relative whom he has left to mourn his loss is a sister. He contributed several able articles in 1877 to medical journals, one of which was entitled "A Case of Determined Suicidal Melancholia."

AMALGAMATION OF THE IMPERIAL AND INDIAN MEDICAL DEPARTMENTS.

A REPORT reaches us as we are going to press that an important Memorandum has reached the India Office from the Government of India, for the consideration of the Secretary of State for India in Council, which proposes that the Imperial and Indian Medical Departments shall be amalgamated, that the rank and privileges of officers who obtained their commissions in the Indian Medical Service prior to 1865 be not interfered with; but that officers who have joined the Service since 1865 shall, according to this scheme, be transferred to the Imperial Medical Department, receiving promotion in their own cadres as vacancies occur in the higher ranks. In order to thin the senior ranks the fifty-five years' rule is to be applied to all officers in Civil employ, the idea being to give officers of the Imperial Service, in course of time, the benefit of the highly-paid Civil appointments in India, which are now held exclusively by the Indian officers. This being a matter of momentous importance to medical officers in the Services we propose returning to the subject, with the prospect of further information for the guidance of those most interested.

NOTICES TO CORRESPONDENTS.

DR. G.—Correspondents would save time when a reply is wanted in the next number of the *Medical Press* by addressing their letters to the Editor at the office of the Journal in that division of the United Kingdom in which they reside.

F. M. S.—The gentleman referred to has peculiar crochets, but we rather lean to the opinion that he is right in the present instance.

STUDENTS.—The article on Students' Books was omitted in our "Student's Number" for want of space; you will find the advice you seek under the head of "Books and Reading for Students" in our issue for Sept. 23.

THE DANGERS OF SCHOOLS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Your excellent article on "The Dangers of Schools" (Sept. 14) is likely to produce some good effects, as the daily press, following your line, has now taken up the matter, notably the *Standard* of Wednesday, Sept. 23, in which an able leader, referring to, and coinciding with, your views, appears.

Every medical man of experience, properly educated in his profession, can confirm the truth of your remarks. Of course, there is a chorus of illiterate schoolmasters, the composition and spirit of whose letters reveal the innate vulgarity of the writers who are denying the charge in the columns of your daily contemporaries. I hope you will return to the subject, for it is very likely that a Bill, in which the evidence of medical men would be requested, will be brought in next Session to carry out what you have suggested. I do not know if it is the case in every town, but here, in Nottingham, the pupil-teachers beat the children as they like. In proof of this, one has only to ask the first child you meet. I have just asked a little girl, "Do the pupil-teachers in your school ever beat the children?" and she said, "Yes, they have boxed my ears many a time; and they beat us with a pointer, a thick stick as long as the (holding her hands about two feet apart).

Of course, the assaults on little children will be somewhat discontinued now attention is turned to them; so, in anticipation of a Bill in Parliament, information of the practices in Board schools now should be obtained.

If nothing is done the abuse will commence again as soon as the public have forgotten it, and be continued until another death, traced to its cause, arrests the attention of the public.

I am, Sir, yours faithfully.

A NOTTINGHAM SURGEON.

AN EMBARRASSED STUDENT.—We cannot do other than recommend again the plan advocated in our "Student's Number." Be guided chiefly by your own impressions, for you are in the position of being able to judge for yourself as to the comparative advantages of hos-

pitals better than most fresh students. We must decline to reply definitely as to the particular school you name, further than to say that in consequence of the disorganization it is suffering from it would not be selected by us on behalf of any student in whom we were particularly interested. The work is not a students' book, and is not likely to be calculated to serve your immediate purpose. For reference it will be valuable.

DR. T. M. D.—The subject of the Fothergillian Prize Essay for March, 1882, is "On Whooping-Cough: its Pathology and Treatment." Essays must be sent to the Registrar of the Medical Society of London by the 1st of November. Probably the letter addressed to the corresponding Secretary for information miscarried.

MR. WARD.—We are aware that it would be useless to request you not to take fragmentary paragraphs or illustrations out of the *Medical Press* to further your crazy notions. But we would beg of you to be honest enough to give the name of the Journal, so that the section to which you appeal may at least have the opportunity of reading the whole, instead of the fragmentary passages, which by themselves appear to convey an opposite meaning to that intended.

THE SOCIETIES.—All the Medical Societies will be in full session during the present month, the first to commence being the Obstetrical Society of London, which holds its Inaugural Meeting this (Wednesday) evening, when a paper will be read by Mr. G. Ernest Herman "On the Relation of Anteflexion of the Uterus to Dysmenorrhœa."

Vacancies.

Brompton Hospital for Diseases of the Chest.—Resident Clinical Assistant. Applications to the Hon. Sec. on or before Oct. 15. (See Advt.)

City of London Union.—Assistant Medical Officer and Dispenser for the Infirmary at Bow. Salary, £100, with board. Applications to be made on printed form, obtainable at the Office, 51 Bartholomew Close, City.

Dreadnought Seamen's Hospital, Greenwich.—House Surgeon. Salary, £50, with board. Applications to the Secretary by Oct. 8.

Lisburn Union, Knocknadona Dispensary.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, Oct. 12.

Manchester Clinical Hospital.—House Surgeon. Salary, £50, with board. Applications to the Secretary, 86 Burton Arcade, by Oct. 8.

Nenagh Union, Toomavara Dispensary.—Medical Officer. Salary, £100, and £10 as Medical Officer of Health. Election, Oct. 11.

Sussex County Hospital.—Assistant House Surgeon. Salary, £40, with board. Applications to the Secretary at Brighton.

Appointments.

BROSTER, A. E., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Bramington District of the Ashbourne Union.

DAVIES, S., B.A., Resident Clinical Assistant to the East London Children's Hospital.

GRIFFITH, G. B., B., C.M. Glas., Medical Officer and Public Vaccinator for the Wansford District of the Carnarvon Union.

LAWSON, T. C., M.R.C.S., Medical Officer for the Fourth District of the Reigate Union.

LLOYD, D., M.R.C.S., Assistant Medical Officer for the Infirmary and the Workhouse of St. Leonard's (Shoreditch)-Parish.

ORMSBY, J., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the St. Mary's District of the Dover Union.

ORB, W. Y., M.B. Ed., M.R.C.S., Assistant House Surgeon to the Northern Hospital, Liverpool.

PARKER, W. E., B.A., M.B. Cantab., M.R.C.S., House Physician to the Northern Hospital, Liverpool.

SMAILLES, F. W., L.R.C.P., L.R.C.S. Ed., Medical Officer for the District and Workhouse of the Pickering Union.

Births.

ARNOTT.—Sept. 20, at the Vicarage, Bussage, Gloucestershire, the wife of the Rev. H. Arnott, F.R.C.S., of a daughter.

LUOBY.—Sept. 23, at The Elms, Bush Hill Park, Enfield, the wife of W. C. Lucy, M.D., of a daughter.

M'CAETHY.—Sept. 26, at "The Farm," Bandon, co. Cork, the wife of Dr. Ed. Cudmore M'Carthy, of a daughter.

STEWART.—Sept. 29, at 19 Charlotte Square, Edinburgh, the wife of Prof. Grainger Stewart, M.D., of a son.

Marriages.

COROLLY-ROUCH.—Sept. 29, at St. Paul's Church, Greenwich, Beaumont Rowley Conolly, M.D., to Helen Rouch, of Madeira.

DRURY-D'ARCY.—Sept. 23, at the Parish Church, St. Mary Abbot's, Kensington, Edward Drury, M.D., to Isabel Jane, youngest daughter of the late Rev. John D'Arcy, rector of Galway.

POWELL-NICHOLS.—Sept. 27, at St. Stephen's Church, Norwich, the Rev. Arthur W. Powell, to Alice, daughter of the late F. Nichols, F.R.C.S., of Norwich.

Deaths.

ADDISON.—Sept. 26, at 10 Albert Road, Brighton, William Addison, F.R.S., F.R.C.P., &c., in his 50th year.

BATTYE.—Sept. 23, at his residence, St. George's Road, S.W., E. Farwell Battye, M.R.C.P. Ed., M. & C.M., in his 61st year.

BOISBRAGON.—Sept. 20, at his residence, Danbigh Street, Pimlico, S.W., T. S. G. Boisragon, M.D. Ed., aged 71.

BOULTON.—Sept. 21, at Horncastle, Lincolnshire, Georgiana Caroline, the wife of Albert E. Boulton, M.R.C.S.

CARTE.—Sept. 22, at 14 Northbrooke Road, Dublin; Alexander Carte, M.D., T.C.D., F.R.C.S.

GAINFORD.—Sept. 25, at 78 Euston Terrace, Euston Road, after one week's illness, John Gainford, L.R.C.P. & L.R.C.S. Ed., aged 55.

POSTGATE.—Sept. 26, at the London Hospital, Whitechapel, John Postgate, F.R.C.S. (on his return from Germany), aged 60.

THE USE OF MALT EXTRACTS.

By J. MILNER FOTHERGILL, M.D.,

Senior Assistant Physician to the City of London Hospital for Diseases of the Chest (Victoria Park).

PREPARATIONS of malt are now being very extensively used, and are largely advertised by their proprietors. If the directions upon the labels of some preparations are to be taken as a criterion of the ideas prevalent on the matter, the use of malt extracts is, at the present time, somewhat haphazard. This is very undesirable in the interests of all. The patient is not improved, the medical man is dissatisfied; while the preparation is depreciated, often from no fault of its own. Under these circumstances a few words may not be out of place as to what may fairly be expected from a good malt extract; and what precautions must be observed in order to secure its utmost usefulness.

The starch of our food is converted by the ferment of our saliva into sugar, or a soluble matter half-way betwixt starch and sugar, known as dextrine. Starch as starch is insoluble, and therefore requires to be rendered soluble in the digestive act, in order that it may pass from the alimentary canal into the blood. The ferment of the saliva is known as diastase. By its action a great portion of the starch of our food is digested, or made soluble. What starch is left over undigested by the salivary diastase in the stomach undergoes no change there; but is acted upon by the diastase of the pancreas after it has passed out of the stomach. Diastase, whether salivary or pancreatic, is only active in an alkaline medium, and is killed by an acid. Consequently, the digestive act in the stomach does not affect the digestion of starch. It is essential to have clear views upon the subject.

When the salivary diastase is brought into contact with starch in the mouth, the transformation commences. The starch so rendered soluble readily passes through the walls of the stomach, and so does not impede gastric digestion. But when the salivary diastase is imperfect,

then a quantity of undigested starch harrasses, and hampers the digestive act in the stomach. It then becomes desirable to improve the digestion of starch by resort to an artificial digestive agent; and for this purpose we use an extract of malt.

The chemical change brought about in the act of malting, is the conversion of the starch of the barley into sugar and dextrine, soluble matters capable of being converted into alcohol, and carbonic acid under the influence of yeast, in the process of brewing. Pereira, in his great work, published in 1850, wrote—"Malt. This is barley which has been made to germinate by moisture and warmth, and afterwards dried, by which the vitality of the seed is destroyed. By this process part of the proteine matter of the barley is converted into diastase. This, although it does not constitute more than 1-500th of the malt, serves to effect the conversion of about 40 per cent. of the starch of the seed into grape sugar, or gum (dextrine)." The seed of barley contains than a quantity of diastase, which in the act of germination is converted into dextrine and sugar, for the nutrition of the embryo-plant until it can feed itself. The parent plant stores up food for its offspring in the form of insoluble starch; and, along with it, a ferment, which transforms insoluble starch into soluble sugar for the use of the plant in the act of germination. How the brewer or maltster came upon the matter is unknown. When the physiological chemist found that starch was transformed into dextrine and sugar by diastase in human saliva, the step forward to the use of vegetable diastase was not a long one to take.

To utilise the digestive ferment of the embryo-plant for the necessities of the human infant, was a step forward in the treatment of defective nutrition. But certain cautions must be observed in such use of vegetable diastase, else it is rendered inutile and inoperative. It must be so used as to supplement the natural diastase of the saliva. When cooked starch is eaten salivary diastase acts quickly upon it, and liquefies it. This is accomplished in a very brief time, viz., while the food is in the mouth, while it is passing down the gullet, and in the stomach before the contents of the stomach become acid. "When a meal is

swallowed it takes some time for the gastric juice to permeate the mass, and the acidity of the gastric contents is for some time feeble" (Wm. Roberts). Consequently, we see the proper time to give vegetable diastase, as malt extract, is not "immediately after a meal," as some labels direct; for then the acidity of gastric digestion is at its height, and the diastase would at once be killed. It should be given so as to be operative before the stomach becomes distinctly acid.

The old rule of giving children "pudding before meat" is thus seen to be a wise one. The farina was acted upon by the salivary diastase before the stomach became acid; while the acid medium was favourable to the digestion of the albuminoids of the meat which followed. Now the plan is to make the pudding follow the meat, so that the farinaceous food finds the stomach highly acid when it reaches it, and consequently the time allowed for the salivary digestion of starch is too short to be effective: while a quantity of undigested starch in the stomach interferes with the digestive act therein. Farinaceous food should then form the first part of a meal for children, dyspeptics, and invalids.

Now, in order to secure all the advantages which can possibly be derived from malt extracts, it is necessary to follow Nature's processes, not to traverse them. Consequently, malt extract should be taken either (1) with farinaceous food; or (2) immediately after such food. For the first it is admirably adapted by its properties, being sweet and toothsome, so that it can be added to farinaceous messes, with or without milk, previous to their being eaten. One caution is, however, necessary, and that is it should not be added until the mess has so far cooled that it can be sipped. This is Dr. Roberts's rule ("On the Digestive Ferments"). Diastase is killed by a temperature of 147° F., and this is the lowest temperature at which anything can be sipped. Consequently, when the food has become so cool that the nurse can sip it, then the malt extract may be added. It could either be mixed throughout the farinaceous matter, or eaten with it; as the case may be, according to the nature of the food. Or it could be taken immediately after the farinaceous food has been swallowed, so as to operate before the stomach has become too highly acid.

Such then is the proper use of malt extracts in order to secure the full action of the diastase contained in them.

In order to secure the action of vegetable diastase it is necessary to use a preparation of malt extract which has not been heated to more than 140° Fahr., in its manufacture. Some malt extracts are raised to the boiling point in their preparation, and such are rendered useless as artificial digestive agents, because their diastase has been killed by so doing.

Beyond such use as an artificial digester of farina or starch malt extracts have a lesser utility. They contain the phosphates of the grain, and a certain portion of the starch transformed into sugar or dextrine; consequently they are highly nutritive. They can thus advantageously be added to milk either for invalids, or dyspeptics, or for young infants whose salivary digestion of starch is either only developing, or is imperfectly developed. "In the human infant diastase does not appear to exist in sufficient abundance to digest starchy matters effectively until about the sixth or seventh month. Until this period it is therefore not advisable to administer farinaceous food to infants."—(W. Roberts.) It would, then, be well to commence about the sixth month to add a little malt extract to the milk previous to the use of ordinary prepared starch foods.

As a beverage malt extracts may be taken with effervescing water. A little malt extract in a tumbler half filled with milk, and then filled up with effervescing water as from a syphon or gazogene, would form an admirable sustaining drink in hot weather, or when fatigued; or it might be taken a couple of hours after a meal by those whose assimilation is defective, and who dislike cod-liver oil; with decided advantage in many cases.

These, however, are but minor uses of malt extracts

compared to their utility as aids to the natural digestion of starch by the diastase of the saliva. They are largely adapted for children, but ("Indigestion and Bilioussness," p. 55) "there exists no reason why they should not be more largely given to adults," for whom they will be found equally serviceable.

In all wasting diseases, whether medical or surgical, malt extracts are indicated from their nutritive properties; and some of them also as aiding in the digestion of farinaceous matters.

GERM INOCULATION. (a)

By CHARLES CAMERON, M.D., LL.D., M.P.

I HAVE thought that I could not choose a more appropriate theme for the address which, as President of the Health Department of this Association, I am called upon to deliver, than the light cast by recent discoveries upon the nature of virulent and infectious maladies, the practical account to which these discoveries have already been turned, and one or two lessons which they suggest in connection with the preservation of the public health.

The first idea to be grasped is that specific diseases are like specific forms of animal or vegetable life—they can be produced only by specific pre-existing germs or seeds. There is no such thing as spontaneous generation of the entities which cause disease, any more than there is of the innumerable forms of animal and vegetable life which make their appearance wherever a material suitable for their development is exposed to the atmosphere.

We know that the air is full of floating living particles, ready to spring into activity whenever they may light upon a congenial soil. We know that in such numbers do they in many cases exist, that present but the proper soil, and the appropriate germ inevitably finds its way to it. We know, on the other hand, that but filter the air, purify it from such germs, and without their intervention no form of life can arise. It has long been suspected that the same was the case with certain specific diseases, especially with what are known as zymotic diseases.

Now, it is a remarkable illustration of the impossibility of foreseeing to what results any scientific investigation or discovery may lead, that the great advance recently made in our knowledge as to the causation of disease, is to be traced to a very large extent to certain investigations made by a French chemist, M. Pasteur, with regard to fermentation. These researches were undertaken with the view of enabling the French wine-grower to avoid those losses to which he was exposed from the want of means of controlling the ferments on which the change of the grape-juice into wine depends. The ferment spores which make their way to it are not homogeneous, and according to the nature of the medium in which they find themselves they develop what from the wine-grower's point of view is regarded as a healthy or unhealthy fermentation, and give rise to a sound or a diseased wine. To control, then, these diseases of wines was the object of M. Pasteur's researches, the result of which has been to throw a flood of light upon the real nature of disease.

In the first place, it was facts elicited in the course of M. Pasteur's investigations on fermentation that first suggested to Lister the theory on which his method is based. Taking Pasteur's researches regarding fermentation and the allied subject of spontaneous generation in connection with these facts, Lister asked himself whether this difference might not be due to the disturbing fermentative action of invisible organisms borne to the surface of the wound by the atmosphere. If so, if these could be destroyed suppuration would be averted, and the fracture where the bone had pierced the skin might be repaired as easily as that where the skin remained intact; the incision made in amputating a limb would give rise to as little constitutional disturbance and would heal as readily as the internal cut

(a) Abstract of an Address delivered before the Social Science Congress at Dublin, Oct. 6, 1881.

which had been so contrived by the surgeon that no air could find access to it. The experiment was made. By careful use of carbolic acid the air-borne germs were destroyed, and the results followed for which Lister had ventured to hope.

For many years microscopists have been aware of the existence of apparently independent living organisms in the blood and tissues of animals suffering from various diseases, but of their nature, and of their relation to the disease, or whether in fact they had anything to do with it, little or nothing was known. The first systematic investigation into the subject attended with striking practical results may be said to be that undertaken by M. Pasteur into what was known as the disease of silkworms. In 1853 the quantity of silk produced in France had reached some 26,000 tons, a tenth of the produce of the whole world. In 1854 a falling off commenced, and this progressed so rapidly that in 1865 the crop was less than one-fifth of the amount I have named. This result was due to a disease which had appeared among the silkworms, and which threatened rapidly to extinguish one of the most important industries in France. At this juncture the French Minister of Agriculture commissioned M. Pasteur, whose researches concerning the process of fermentation had been attended with such remarkable results, to undertake an investigation into the malady which was destroying the silkworm. The result was, as he had shown the wine-grower how noxious fermentation might be guarded against, so now he showed the silk-producer how the silkworm could be regenerated and the disease stamped out. Previous observers had noticed in the juices of diseased silkworms tiny microscopic corpuscles, but of their nature, or the rôle which they played in the disease, nothing definite was known. To these M. Pasteur directed his attention. He soon ascertained that they were living organisms, which, multiplying themselves in the silkworm's body, constituted the real cause of the malady. By watching their development M. Pasteur made this important discovery, that they take a considerable time to spread within the insect's tissues to such an extent as to do very much mischief. If a healthy larva was not infected until it had completed a portion of its existence, the ravages of the disease had made comparatively little progress when it entered into the chrysalis stage. It spun an excellent cocoon, and for the purposes of the silkwormer was as valuable as its healthy neighbour. If, however, it were reserved for the production of eggs, the corpuscle had by the time it became a butterfly made such progress within its body, that it had penetrated even into the eggs it produced, and a greater or smaller proportion of these contained corpuscles. The silkworm which issued from an infected egg inevitably died before it could produce silk. But M. Pasteur observed that even among the eggs produced by the most infected butterfly a certain proportion were sound. Here, then, was a fact which, properly utilised, might enable him to restore to health the valuable indigenous breed of the insect. For it must be remembered that although, by the expedient of procuring his eggs from uninfected countries, the French silk-grower might to a certain extent maintain his crop, he did so only by abandoning a race which by careful cultivation had been brought to a great state of perfection, and resorting to another in every respect its inferior. Availing himself, therefore, of the fact that if even a small percentage of the eggs were undiseased their offspring would, if their health could be preserved, suffice for the establishment of a regenerated and healthy race, M. Pasteur devised a system whereby each silkworm was reared by itself under careful observation, and in conditions which would ensure the healthy insects against infection. The eggs of those that retained their health to the last—of insects which after they had laid their eggs the microscope showed to be free from the disease—were found to produce a perfectly healthy race. By breeding only from such stock, by avoiding conditions favourable to the production of the disease from germs which might find their way from without, M. Pasteur showed that in a

short time it would be possible to regenerate the race and entirely to stamp out the disease. He showed, too, how, when circumstances did not admit of such elaborate precautions, a seed might be secured which, if not absolutely free from the disease, would still afford a very satisfactory crop. By a series of striking demonstrations he converted the silk-grower to his views, and his services obtained the recognition not only of his own but of foreign Governments.

It is thirty years since Dr. Davaine discovered that in the splenic fever of sheep and cattle—a terrible fatal disease, which Continental writers identify as the plague sent upon the cattle of Egypt—a tiny microscopic organism, measuring the fraction of a thousandth part of an inch, was to be found in the blood; and subsequent researches induced him to believe that this was the true cause of that disease. As time passed, other microscopic beings were discovered in the blood and tissues in other diseases. I will not trouble you with any attempt to describe the differences which these organisms present, for subsequent experience has shown that the most deadly may be undistinguishable from the most harmless by any detectable physical peculiarity. Like many of the lowest forms of vegetation, they exhibit movements when viewed under the microscope, and multiply themselves with extraordinary rapidity, in certain circumstances by budding or subdivision like the yeast plant, and in others by the production of germs or spores. In 1868, while M. Pasteur was engaged in his researches on the silkworm disease, M. Chauveau, a distinguished veterinary surgeon of Lyons, proved that the activity of every form of infectious virus was due not to its solid or gaseous constituents, but to organised particles which it contained. In 1876, Dr. Koch, a German physician, succeeded in isolating the little rod-like organism or bacterium which gave rise to the splenic fever of which I have spoken, and in cultivating it outside the animal body. In this he only repeated what M. Pasteur had long before done in the case of ferments, when—in order to study their action uncomplicated by the effects of the media in which they were ordinarily found—he had devised the method of cultivating them in inorganic solutions containing the elements necessary for their growth. But Dr. Koch's success was of immense scientific importance, for whereas it had before been impossible satisfactorily to observe the development and peculiarities of any of these organisms, or even to prove beyond possibility of cavil that it was they, and not the organic media in which they were found, which when inoculated on other animals gave rise to the disease, it now became practicable to remove them from all possible contamination, and to prove that this or that organism was really the cause of this or that malady. Dr. Koch's discovery was rapidly followed up by that of Dr. Klein, an eminent German physiologist resident in London, who showed by methods similar to those adopted by Koch, that the disease known as pig typhoid or pig plague was also the result of a microscopic organism which he succeeded in cultivating; and about two years ago M. Toussaint, a veterinary surgeon of Toulouse, to whom also I shall frequently again have occasion to refer, achieved a like success with the bacterium of fowl cholera. I may say in passing that this is a disease in no respect resembling cholera, but from the circumstance of its having ravaged the poultry yards of France coincidentally with an epidemic of human cholera, it acquired that unfortunate title. M. Pasteur had been engaged for some time, at the instance of the French Government, investigating the causes of the splenic fever which annually wrought such havoc among the flocks and herds of France, and the result of Toussaint's discovery naturally directed his attention to a disease presenting peculiar facilities for experiment, and possessing this feature in common with the splenic fever of cattle, that it had been proved to be of similar parasitic origin. Having once brought to bear upon this fowl cholera, then, his extraordinary scientific instincts and great experience, M. Pasteur was able in February of last year to

announce to the French Academy of Sciences a series of discoveries, which, followed up as they have been by himself and others, have completely revolutionised our ideas of the nature of diseases and the proper methods of dealing with them. Within little more than a year and a half—thanks to the enterprise and emulation of French investigators—a new Romance World of Contagions has been opened up, peopled with innumerable microscopic races, which every week shows to be more and more susceptible to human domination and control, but many of which are—till tamed by science—so fatal to mankind that the slightest carelessness on the part of the experimenter, the accident of a scratch on the hand, might any day entail upon him a rapid and appalling death.

(To be continued.)

HOSPITALS UNDER STATE SUPERVISION. (a)

By HENRY C. BURDETT, F.S.S.

WITHIN the last five years no less than four influential deputations have sought interviews with the Secretary of State for the Home Department for the time being, with the object of obtaining a Royal Commission of Investigation into the subject. The first consisted of representatives of the treasurers and managing bodies. The second included in addition many governors, medical men, and philanthropists. The third deputation attended as the representatives of the patients treated, and of those ratepayers and public bodies which are more immediately interested. Lastly, the medical profession was represented by members of the British Medical Association. This Commission was asked for especially with the view of obtaining reliable data upon which to base the needful reforms, and to secure that the present system of medical education and relief shall cease to be inadequate and unsatisfactory, as it undoubtedly and undeniably is at the present time.

It will be desirable, however, to examine into the circumstances as they are known to exist, which have produced so active and unanimous a desire for inquiry. For the sake of brevity, as space and time are matters of moment, the subject has been divided into seven propositions embracing the whole question. These will now in turn be briefly considered.

I. The present system of hospital administration is attended with many anomalies which call for public inquiry. In London especially, the hospital accommodation is imperfectly distributed, and in many districts is altogether inadequate.

The administration of the hospitals as at present conducted is so uncertain and unsatisfactory that inquiry is needed to secure amelioration in the interests of the poor. The tables which accompany this paper show that the cost of administering, *i.e.*, the cost of management, in sixty-one general hospitals varies from 2½ per cent. at Cork, to 27½ per cent. at the Metropolitan Free Hospital; the cost per patient per week from 9s. 4d. at the Cork County Hospital, to £3 0s. 4d. at the Leeds General Infirmary.

A difference of 25 per cent. in the cost of management, and of nearly 700 per cent. in the cost of maintaining the patients, would alone warrant the appointment of a Commission. The special hospitals show equally startling discrepancies. Thus in the 110 institutions enumerated in the tables, the cost of management varies from 55 per cent. at the Chelsea Hospital for Women to 3½ per cent. at the Liverpool Fever Hospital, and to 1½ per cent. at the Corstorphine Convalescent Home, Edinburgh. The cost of each in-patient varies from 9s. at the Western Ophthalmic, 10s. at the Royal Orthopædic, and 10s. 6d. at the National Hospital for Diseases of the Heart and Paralysis, to 63s. 3d. at the

Establishment for Gentlewomen, 43s. 6d. at the Chelsea Hospital for Women, and 42s. 5d. at St. John's Hospital for Skin Diseases.

Turning now to the distribution of hospital accommodation, nearly nine-tenths of the bed accommodation in the London hospitals is situated within a radius of a mile and a-half from Charing Cross, and in a space that can be covered by one's hand. The population of London resident within the metropolitan area, and exclusive of the large number of persons who are annually sent to London for hospital treatment, cannot be less than four and a-half millions, one-third of which number is annually relieved at the London hospitals. Out of a total of 4,579 beds for the whole metropolis, 3,486 are provided by the hospitals situated in the narrow area above specified.

It may further be pointed out that at present North London, with a population of nearly 1,000,000, possesses but one hospital, the Great Northern, with 33 beds; the East End, with its river-side and manufacturing population of 1,100,000, is dependent upon the London Hospital with 790 beds, and the Metropolitan Free Hospital with twenty beds, both of which are inconveniently situated for a large proportion of its inhabitants. The West End, with a population of 950,000, has but two hospitals—St. Mary's with 190, and the West London with 60 beds respectively. A population of nearly one and a-half millions on the Surrey side of the Thames has to rely on Guy's with 700 beds, and St. Thomas's with 400 available beds, both of which, though largely endowed, are situated miles away from a portion of the district to the wants of which they nominally minister. These facts are incontrovertible, and the need of a Hospital Commission to control the action of the governing authorities of the two last hospitals has been forcibly illustrated by the recent scandals at Guy's, and by the fact that the present buildings which constitute St. Thomas's Hospital cost in round numbers £600,000; that one of the pavilions is not intended for patients, but constitutes a palace only recently occupied as a residence for the treasurer; that this expenditure not only swallowed up all the purchase money paid for the old site and materials, but rendered it necessary to mortgage part of the income to the Charity Commissioners for a loan of £30,000, which sum was wholly expended upon the buildings, so that the money for furnishing and placing beds in the wards had to be raised by an appeal to the public; and that, in consequence of this gross improvidence, a portion of the building is, and is likely to remain, absolutely empty, because the hospital finances have been so grievously crippled that there is no income to maintain the beds for which such ample accommodation has been provided. This reckless and culpable extravagance is not confined to one hospital, or to London, as the hospital buildings at Wolverhampton, Leeds, Norwich, and in many parts of the country eloquently testify. Examples of the fruits of the present irresponsible system on which some of the hospitals are governed might easily be multiplied, but enough has surely been said to establish the first proposition.

II. The unsatisfactory condition of the present outpatient system, and especially of that in force at the large metropolitan hospitals, demands reform.

No one will dispute this self-evident proposition. At the present time more than a million people, or one in three, receive relief at the London hospitals, in Liverpool one in two, and in Birmingham two and a-half of the whole population are at present in receipt of free medical relief. The treasurer of one of the largest endowed hospitals said, three years ago, that the funds of our larger hospitals were not applied in the best possible manner, or quite with due regard to the wishes of the founders. About 600,000 people came annually to thirteen of the best hospitals in London for medical advice and assistance, at an annual cost of £15,000 in

(a) Abstract of Paper read before the Public Health Section of the Social Science Congress at Dublin, October 5th, 1881.

medicine alone. The average attendance of these patients is from three to seven hours before each can be attended to, and the rush is so extreme that the medical advice they received is almost perfunctory. It has been well said that the time and attention of eminent physicians and surgeons are generously placed at the service of the poor, but unfortunately eminent persons have no more time than persons who are not eminent, and when a million out-door patients apply at the London hospitals in one year, it becomes rather a delicate arithmetical problem, how many seconds can be bestowed on each of them. (a)

III. It is desirable that every hospital and medical institution intended for the relief of the suffering poor shall be administered by a board of management, subject to periodical election by the governors, upon which board the medical staff of the charity should be adequately represented.

IV. An authoritative supervision over the administration, and a public audit of the accounts of all such institutions is needed to secure a right distribution of medical relief, and a more economical expenditure of the funds entrusted to the boards of management.

These propositions relate to the internal government of the hospitals. It may be said that the old system of managing the endowed and many other hospitals has proved not only a conspicuous failure economically, but it has failed in matters of still greater moment. Under the government of a treasurer of the accustomed kind, the necessary medical knowledge cannot be brought to bear, except by the maintenance, on his part, of the most cordial relations with the medical staff, and by his full recognition of the fact that, in many matters of the greatest weight, he must walk blindfold unless he is guided by their counsel. At St. Thomas's, unfortunately, this condition has not recently been fulfilled. The consequences of the friction between the treasurer and the staff have been at many points ludicrous and at all calamitous. If we are correctly informed, the patients suffered terribly from pyæmia and other "hospital" diseases, which have been shown by modern research to be traceable almost always to want of common sanitary supervision; and, in a general way, it may be fairly said that the new St. Thomas's has been among the least successfully managed hospitals in London. Its funds have been squandered foolishly; its opportunities for so doing have been curtailed; and the advancement of science and the education of students, in so far as they have been accomplished, have been accomplished in the face of artificial difficulties and obstacles, created by those whose first business it should have been to remove them. Of late years the antagonism between the treasurer and the medical staff appears to have reached such a point that the customary annual dinner of the governors had to be abandoned, and at least one very distinguished teacher transferred his services to another hospital, in order to avoid a conflict which would otherwise have been forced upon him. (b)

The notorious facts in connection with Guy's Hospital have been specially brought to the notice of the Home Secretary by a deputation on a recent occasion, and it is not necessary to allude to them further here, except to say that they endorse in a very remarkable manner the condemnation of the present system of managing these great hospitals, which the writer in the *Times* has so forcibly delivered. At St. Bartholomew's Hospital matters have been managed in quietude, if not with efficiency.

V. The absence of organisation and combination amongst the medical institutions throughout the country, materially lessens their usefulness.

On this proposition little need be said. It is strongly enforced by the enormous and needless difference in the

cost of maintenance and management brought out by the tables already referred to. The absence of this combination or co-operation leads to lamentable extravagance, an enormous waste of money, owing to the repetition of an expenditure in the management of very many charities, the objects of which could be far better carried out under one roof. Hospital finance, accounts, supply, the general question of the uses and abuses of hospitals, the relations of dispensaries, and especially of provident dispensaries, to hospitals, the reproduction of exploded abuses, and the adequate trial of new systems can alone be rightly judged, decided upon, or prevented by means of this co-operation, and the sooner it is brought about the better will it be for the welfare of all classes of the community.

VI. In the administration of the wards, so far as it affects the treatment of the patients, and especially in the management of the nursing arrangements, the medical staff should have an authoritative voice.

No one who knows anything about the management of a hospital has any doubt on this subject. Yet the old system not only attempts, as in the case of Guy's Hospital, to openly defy public and professional opinion in this matter, but its audacity leads it to brave the interference of a court of law by studiously excluding all medical men from the governing body, in distinct contravention of the original and expressed views and intentions of the founder himself. It really resolves itself into the question, Is the patient for the nurse, or the nurse for the patient? If the former is to be the principle upon which modern hospital nursing is to be conducted for the future, hospitals must soon cease to exist, because patients will cease to seek admission to their wards. The cases admitted to a clinical hospital are selected on account of their severity, and their proper treatment must embrace the attendance of the best trained nurses. It is a needless cruelty to place a severe case of acute disease under the care of a raw practitioner who knows next to nothing about nursing, and the remembrance of this fact alone ought to prevent the attachment of a school for training nurses to any clinical hospital whatever. If the patient's welfare is to be adequately considered, this proposition is unanswerable, especially when it is remembered that to train a nurse for her duties it becomes necessary to constantly change her from ward to ward, a system which would be fatal to the interests of any patient who was dangerously ill. It will no doubt astonish many people to hear that in the majority of the large hospitals the nursing arrangements are under the control of a matron, unaided by a nursing committee, and only indirectly, if at all, assisted by those alone qualified to direct, viz., the medical staff. Out of twenty-two hospitals having medical schools, there are but seven where this important department is superintended by a nursing committee upon which the medical element is represented. Of course the greater includes the less, and so the practice at the chief hospitals in a matter like this becomes the law which guides hospital managers throughout the country.

VII. The importance of medical education, and the adequate training of the members of the medical profession, require an intelligent recognition of the relation of the hospitals to their medical schools, to insure an improvement in such relations.

Inquiries on these points made at all the important hospitals in the metropolis and the country show that their consideration is almost entirely neglected by the persons who ought to foster their growth. So little do the governors recognise their responsibilities, that in most schools the buildings are inadequate for the purpose in consequence of being mainly, if not altogether, erected at the expense of the teachers, who are merely tenants at will. Notwithstanding that the museums, so essential for guidance in treatment and educational purposes, are, almost without exception, claimed as the property of the hospital authorities, yet contributions

(a) Speech of H.R.H. Prince Leopold at the annual meeting of the Charity Organisation Society.

(b) Leading article in the *Times*, Nov. 13, 1877.

towards their development and maintenance are made by only six out of the eleven metropolitan, and by four out of eleven country hospitals. In the case of the former £1,000 per annum would more than cover the grants thus made. Seven of the country and five of the metropolitan hospitals contribute absolutely nothing to either museum or school, while four of the latter actually retain a portion of the school fees. It cannot be right that the development of so important an item in a nation's economy should depend on the voluntary efforts of those who, while willing, have not the power to elevate medical science to its proper position. Furthermore, hospital authorities are seemingly unaware of the obligation laid upon them of nurturing and training able physicians and surgeons for the service of the State.

Again, with adequate representation of the medical staff upon the boards of management of the hospital, and of the governors upon the school committees, an intimate acquaintance with the practical requirements of these joint institutions would secure the highest efficiency in the administration of the whole.

During recent years the Metropolitan Asylums Board have built and opened some of the most extensive and complete of modern hospitals. These splendid Poor-law infirmaries have provided accommodation for nearly 10,000 in-patients. They are placed in charge of paid resident medical officers, whose clerical duties, under the present system, are so onerous that they have far too little time to devote to the treatment of the cases entrusted to their care. These infirmaries form a magnificent field for the treatment and investigation of disease, for pathological research, and for medical education. The Marylebone Infirmary, prior to its being brought under the operation of the Poor law, was an instance of what these institutions might become, with great advantage to the inmates, as aids to the progress of medical science.

It may not be out of place to say here that in Sweden the Government have for years worked the hospitals on a system which would confer great benefit upon our own towns, by bringing the Poor-law and voluntary institutions into more intimate association, though managed by separate governing bodies. This has been secured in Sweden by a scale of charges demanded from all patients who are admitted to the hospital. The first grade pays a substantial sum and obtains anything and everything the patient may care to have or to pay for, subject to the control of the doctor. The second pay a much less, but a remunerative rate, for all that they receive at the hospital; and the third class are paupers who are paid for on an agreed scale by the Poor-law authorities. Thus well-to-do, thrifty artisan and improvident pauper are all treated by one staff, controlled by one administration, and are located in immediate proximity to each other, though in separate pavilions. This the writer believes to be the true system to aim at securing, and he hopes that ultimately some such plan will find acceptance in Great Britain to the advantage of everyone concerned. This suggestion is, however, at best but a digression from the purpose of this paper. In the same way, following the example of Paris, a central store might be established in London at which all the hospitals could purchase, at a little over cost price, every article of consumption, from an egg to a wooden leg. An arrangement of this kind would tend to reduce the large discrepancies as to the relative cost of patients which at present exist between one hospital and another, and any one purchasing at the store would have a guarantee that the article supplied was not only of moderate price, but the best and most suitable of its kind. In the same way, by combination, the reliable income of all hospitals might be raised at a fourth of the present cost through one common agency. The establishment of one central office for all the London hospitals, for instance, for the collection of old subscriptions, would not only save a vast expenditure upon

management, but prevent annoyance to many charitable people by abolishing multiple and duplicate appeals.

It would not be difficult to multiply instances of ill-advised hospital erection or extension, but enough have already been given, and only two more need be added here. The Brompton Consumption Hospital, one of the most valuable of English medical charities, is expending on its new wing nearly all its funded property, thereby throwing a burden on the public to the extent of £10,000 per annum. St. Thomas's Hospital has been forced by the folly of overbuilding to hand over one wing to the well-to-do, and to admit paying patients into other wards in order to maintain its present reduced number of beds. Nearly everywhere the building mania seems to have blinded hospital managers, so that similar extravagances, going far beyond the requirements of the districts in which the hospitals are situated, and entailing half-empty wards and increased cost of maintenance, are becoming the rule and not the exception. The indiscriminate institution of special hospitals and dispensaries is productive of evil, and a controlling power is urgently called for to prevent the multiplication of so-called charities, which—oftentimes springing from unworthy motives—decoy charitable funds from legitimate channels. Such examples of ill-advised expenditure reflect directly or indirectly great injury upon the poor, for whose benefit the large sums concerned were originally intended.

The social and public aspects of this great question of the right government of our hospitals alone demand an immediate investigation. When something like one million and a quarter of the population of London annually seek and receive gratuitous medical relief, and when the whole wage receiving class in the Metropolis, if we take the census of 1871 for a basis, and include all who by position or occupation are not above this class, cannot be estimated at more than 1,400,000—whatever deductions may reasonably be made for a certain number of patients appearing more than once on the lists in the same year—there is enough remaining to warrant an independent inquiry into the whole question by a Royal Commission.

OPIMUM AS A LUXURY, AND IN THE TREATMENT OF DISEASE.

By HERBERT PARSONS, M.R.C.S.

Formerly Resident Medical Officer St. Mary's Hospital, London.

(Concluded from page 293.)

DELIRIUM tremens is a disease in which we have the opportunity of seeing at one time bad, at another good, effects produced by opium. Sometimes the delirium will readily be amenable to it, sometimes not till after the exhibition of enormous doses, and sometimes the conditions will be aggravated by it. Why is this? In no class of disease is a merely nominal diagnosis sufficient to narrate any line of treatment, and it has been frequently pointed out by eminent pathologists that, in this disease, the condition of the brain, though always highly excitable, varies greatly as to blood supply. In some cases, anæmia, in other, hyperæmia, may be the immediate cause of inducing this disease in a brain already prepared for its onset by alcoholic excesses.

Occasionally toppers will indulge for years without ever experiencing an attack of the "horrors," but, at the last, meet with an accident, in which they lose much blood, or after which they are deprived of their stimulant; this acting in a debilitating way on his brain, he has to pay the penalty of his indulgence in an attack of delirium tremens. In this case anæmia may rather be surmised than hyperæmia, and here chloral, bromide of potassium, and stimulants, are more suitable, and likely to be productive of benefit than opium. But, in other cases, the delirium tremens is the result of a more extensive debauch

than usual, and is accompanied by unmistakable signs of cerebral hyperæmia. Then opium, or preferably injections of morphia, produce the very best result, though often not till after large and repeated doses. In this sort of case, all preparations given by the mouth will fail, but given subcutaneously, will prove effective. In other forms of the disease, where we have no grounds to suppose the circulation in the brain in any way deranged, we must be doubtful as to whether opium will be productive of good or harm, but it is always worth a trial, more especially if other drugs have failed, as they so often do; and it must be remembered that large doses only can be expected to do good.

In the treatment of delirium tremens the fact must not be lost sight of that if left to itself, and allowed to run its natural course, it almost always ends in perfect recovery. But, all the same, it is often practically impossible to let it go on unchecked, both on account of want of proper means of control, and for the sake of other people. In cases where death occurs, it is often difficult to say whether it is the result of the disease, or of the remedies used for its cure. Dr. Handfield Jones has shown that frequently when opium fails by itself, yet after a fore-running dose of bromide of potash it will produce the very best effect; whatever may be the cause of this, there is no doubt of the fact, and those who try it will be astonished at the results; again and again I have seen delirium of all kinds, where either drug has failed separately, calmed by the two given in succession, or together. I may mention, should all drugs fail, as they sometimes do, we always have an infallible remedy in chloroform, during the influence of which injections of morphia may be given, till, at the end, the patient recovers from narcosis only to fall into quiet sleep.

Another class of cases which opium is usually competent to cure, is headache, dependent on hyperæmia of the brain. These headaches occur in strong full blood, or in persons of an excitable temperament, and are often connected with gastric derangement. These headaches are brought on by any extra exertion or extra excitement. These persons say they have a tendency to rush of blood to the head; that is to say, the heart's action is readily stimulated to extra exertion, so that more blood is sent into the carotids than usual, while the vaso-motor nerves of the head not having tone sufficient, all the arteries are dilated, so that more blood is sent upwards, filling the circulatory system of the dura-mater and brain. This shows itself by throbbing tensive pain in the forehead and temples, a feeling both subjective and objective of heat in the integument of the head, a dizziness and humming in the ear, and hypersensitiveness to all external impressions. A small dose of any form of opium will invariably ease the pain, though the feeling it substitutes may, to some, be nearly as bad, while, to others, nothing results but entire freedom from pain, and this is more likely to occur if perfect rest is taken immediately after the exhibition of the drug. It is not to be recommended that all congestive headaches of this sort should be treated by opium, for among some no doubt there would be a habit of constant consumption of the drug produced, while other methods, as by purging, regulation of diet, &c., would produce more lasting good results, but sometimes these headaches are so severe as to be unbearable, and it is well to have by us an immediate remedy. For my own part I consider it always a serious matter to give opium, and always to be done with a certain amount of reluctance, for its after effects are sometimes as bad, while if they are but slight, there are many patients who, although they will be purged to an extreme degree with equanimity—may even with gratitude—will regard being made to feel giddy as an unpardonable offence. As frequently, perhaps, is opium used for its anti-spasmodic action as for any other, and in those cases where spasm is accompanied by pain, is, next to chloroform, our most perfect remedy. Thus it relaxes spasm of the muscles of the glottis, urethra, intestines, bronchial tubes, and other organs; but it does more than relax spasm, it decreases

or arrests the contraction of these unstriated muscles. Reason and knowledge, then, will point out in what cases this property is likely to be beneficial, and in those cases it will be administered, unless, indeed, any of its other properties should render its use obnoxious.

The use of opium preparations in certain forms of dyspepsia is worthy of attention, for in cases of this affection it is usually diligently withheld, being supposed capable of nothing but harm; yet, in certain cases, its use is attended with great advantage. Where dyspepsia is consequent on a want of proper quantity of the digestive fluids, of course it would be deleterious. But when it depends on acute or chronic catarrh, small and well-timed doses of some fluid preparation of opium will ease the pain, allay vomiting on the tendency to do so, and diminish the quantity of thick ropy mucus. Acute catarrh is especially amenable to it, but the chronic gastric catarrh of drunkards is also much benefited by it; the flabby-coated tongue improving in appearance, and the morning vomiting ceasing. Pyrosis is generally cured by its exhibition. Then again there is an irritable form of dyspepsia, connected with diarrhoea sometimes, which rapidly subsides under opiate treatment. The liquor morphiae, of the pharmacopoeia is highly useful in diseases of these kinds. Other kinds of dyspepsia, where pain occurs some hours after each meal, can often be cured by it. One of the causes of success in these cases is, perhaps, its producing some torpidity in the bowels, for there is no doubt there is a great sympathy between the stomach and the intestines, and dyspepsia is often attendant on bowel affection, and diarrhoea, especially when artificially produced by purgatives. We may then assume that in many cases opium does good by permitting a normal condition of organs to be regained by physiological rest to the parts.

Diseases of the lungs, though perhaps more common, and producing more deaths than diseases of any other organs, yet are, as a rule, so little amenable to treatment as to tax to the uttermost the resources of the physician. At many times opium is the only drug upon which we can, with certainty, rely, to give even temporary amelioration, but its use is not confined to this, it will sometimes effect more, and even be the means of paving the way to ultimate recovery.

In acute inflammation of the lungs, or their coverings, the use of opiates is usually restricted to the relief of pain, yet this is by no means a slight thing to effect, more especially as by that means it prevents restlessness and anxiety in themselves, sufficient to produce serious aggravation of the disease. It might be used continuously, with a view to cut short the inflammation by virtue of its anti-phlogistic powers before spoken of, but its action on the brain and secretions would probably render it worse than useless in this way.

Slight catarrhs, both of the nasal, laryngeal, and bronchial mucous membranes can frequently be cut short if opium be taken at their commencement, or cured if the affection has already commenced, especially if it is combined with other diaphoretics. In these cases this drug is peculiarly appropriate, for it acts directly on the mucous membranes, astringing their blood-vessels, and stopping the abnormal secretion; and also it dilates the cutaneous vessels, and produces diaphoresis, thus restoring the utaneous function, the checking of which may have produced the catarrh, and also by filling the external circulation depleting the internal. But in bronchitis of a severer form, the blood-vessels have lost their tone too much to react to any contracting agent, we can modify perhaps the severity of the disease, and reduce various symptoms and conditions which militate against recovery, but this, as in all serious inflammatory conditions, is all we can do. Yet this is often a great deal, when we can bear in mind that symptoms which, at first, are produced necessarily by the pathological conditions, afterwards become the worst part of the disease, and the means whereby the abnormal state is continued; I refer to such things as cough, delirium, hypersecretion.

Now the cough in bronchitis and in phthisis is often not only both the most prominent and troublesome part of the disease, but (although of course, to a certain extent, absolutely necessary) also a continual irritant, whereby the amount of secretion is increased, the parts kept from any physiological rest, and the patient worn out and worried. By opiates better than by any other means, as a rule, can we stop the cough by lessening the abnormal excitability of the nerves and their centre, and thus rest is given so that the bronchitis may subside, and the phthisis, if other conditions be favourable, may be delayed in its deadly progress, and even contraction of the already formed cavities take place. Undoubtedly, in acute cases, where a considerable degree of cyanosis is present, as in bronchitis, pneumonia, and broncho-pneumonia, and several other diseases, where the dyspnoea depends on the blocking up of the air-cells and bronchioles by mucus, the clearance of these by coughing, or emetics can alone dissipate the cyanosis, and continue life, and sedatives of any kind would produce death most certainly. But in more chronic cases, opium, by lessening the amount of secretion formed, and diminishing spasm if present, may be of great service. It lessens the amount of secretions directly by astringing the mucous membranes, and indirectly by stopping the cough which is known to be a great cause for the production of mucus. Small and frequent doses of opium are often given, and it is a safe way of administration, as they can be stopped when the effect of them is getting excessive, but, at the same time, beyond this nothing is gained, for the action of opium lasts many hours, and an ordinary dose repeated three times in the day, will generally be sufficient to keep the body under its influence for the whole of the twenty-four hours. A certain degree of cyanosis does not necessarily contraindicate the use of opium, as it after proves beneficial in advanced cases of heart disease, with congested lungs, if the kidneys be not diseased. In the course of phthisis, opium, in some form, has always to be resorted to, though, by some, its use is delayed as long as possible, till the colliquative diarrhoea, and tearing cough, renders its use imperative in order to give one easy moment to these poor wretches. The reason for this procrastination is the fear of deranging by opium the digestive organs, but this can hardly be taken into account by practical men, for how few cases of pulmonary consumption are there which are not accompanied by gastric catarrh, and opium will tend to improve rather than increase the consequent dyspepsia, more especially when there is diarrhoea also.

It is hardly too much to say, then, that in the latter stages of phthisis our only reasonable resort is opium, and to withhold it is cruel. Why should we allow a poor miserable being to perish suffering from profuse night sweats, diarrhoea, cough and sleeplessness, when we have a means of relieving all these, and by so doing, perhaps, prolong life, or, at all events, allow him to go down to his grave in peace. In these cases there ought to be no limit to the amount of opium allowed, and no fear of a habit of opium-eating being contracted, a habit likely to be productive under the circumstances of physical benefit. This drug, then, is of the highest value in all stages of consumption: in the early stages facilitating recovery, later on delaying the progress of the disease, and at the last, mitigating and easing the painful symptoms.

In one more aspect is opium to be considered, namely, as a tonic. In feeble bodily conditions, with a highly excitable nervous system, it acts as a true tonic, strengthening the heart and the nervous system, and thus equalising the circulation, and diminishing the tendency to local congestions and inflammations. In this, as in some other ways, its action resembles arsenic. Again, in plethoric persons and others, often after a very slight amount of exertion, a disproportionately great degree of weariness is felt, consequently little or no exertion can be made. This is, perhaps, to be looked upon as a hyperaesthesia of the spinal cord and nervous centres, so that small impressions produce great effects, the lassitude felt during dyspepsia is perhaps due to the same cause, but whether

this view of its causation is correct or no, there is no doubt of the power of opium to prevent it; doing it by reducing the sensitiveness of the nervous centres.

Department of Lunacy.

ON PERCUSSION OF THE SKULL IN THE DIAGNOSIS OF DISEASE OF THE BRAIN. (a)

By ALEX. ROBERTSON, M.D., F.F.P.S.G.,
Physician to the Town's Hospital and City Parochial Asylum,
Glasgow.

ALTHOUGH attention was directed by me in 1877 to the value of percussion of the skull in the localisation of disease on the surface of the brain, and Dr. Ferrier (b) has also insisted on its importance, the subject may still be considered comparatively new to the profession.

This paper first deals with objections against the practicability of transmitting the degree of force employed in tapping the skull with the finger to the surface of the brain. Duret's experimental researches on cerebral traumatism show that in blows on the head a "cone de depression" is formed, which passes deeply in the line of the thrust to the base of the skull; the slight force of percussion will act in a similar way, though it may scarcely extend beyond the cortical substance. A somewhat analogous instance of the irritation of a morbid part into conscious sensibility is sometimes supplied by disease of the lungs, in percussion over a cavity or softened caseous matter near the surface of the lung.

Clinical experience is apparently conclusive on the question. Cases of Jacksonian epilepsy and monoplegias are referred to, where the symptoms pointed to the motor region of the convolutions as the seat of disease, and in which percussion of the skull elicited very distinctly deep-seated pain in that part of the head and *nowhere else*.

Thus, in two of the cases the spasmodic movement began in the arm, or leg, or face, and thereafter sometimes became general. Though these patients had suffered occasionally from *diffused* headache, they were not conscious of pain at one part more than another till they distinctly realised its presence in the region of the ascending median convolutions, when their skulls were percussed by the finger.

The two kinds of symptoms—the disturbance of function and the developed pain—lend each other mutual support in the localisation of the disease. Further, when the convulsive movements are general, the pain brought out by percussion at some other part of the head, probably indicates the centre from which the morbid action spreads to the motor convolutions. In some cases, corroboration of the diagnosis is derived from the history of former blows, and also from the beneficial effect of treatment over the painful region. Another objection is, that the brain substance is wholly insensitive, and the membranes are only slightly sensitive. In reply, I would point out that the dura mater and the pia mater, like other fibrous membranes, when in a state of disease and subject to tension, may give rise to severe pain.

The pain in the cases founded on, was not induced by

(a) Read in the section of "Medicine" at the International Medical Congress, August, 1881.

(b) It was not till the Congress had met that I learned that in 1874, and therefore three years before me, Dr. Ferrier had noted that pain may occasionally be developed by percussion of the skull in cases of superficial disease of the brain. This is mentioned in a paper by that gentleman on "Pathological Illustrations of Brain Function," in the West Riding Asylum Report for that year. I regret very much that the reference to the point (which only occupies five lines of the paper) should have escaped my notice, and I therefore now, at the earliest opportunity, acknowledge Dr. Ferrier's priority. It will be obvious that the fact of two observers, quite independently of each other, having arrived at the same conclusion, adds much to its value.

mere rubbing or gentle pressure, but by *percussion*. It is, therefore, inferred that the disease is not in the bone, unless it be in the inner table of the skull; and, if it be situated in this part, it is of great importance to elicit the fact, as morbid action there usually involves the outer, and often the inner, membrane and brain itself. However, disease of the bone in adults in most cases is syphilitic, and the pain, as a rule, is such as to stand in no need of artificial development to manifest its existence.

Of the six cases under my care great benefit was derived in some of them from repeated counter-irritation over the seat of developed pain. Other cases, besides the two mentioned, support the prevailing views respecting the localisation of motor function in the cortical substance.

In practising percussion of the skull the physician should be careful to make the taps of the fingers as nearly as possible of equal force, except in the temporal region, where they should be somewhat lighter. It is well to percuss one's own head previously, to ascertain the character of the tap which can be borne without discomfort. It is advisable to avoid, either by remark or otherwise, directing the patients' attention to any particular part of the head, particularly if they be of an impressible or hysterical disposition.

I do not claim that this means of diagnosis will be of very wide application. It probably will not be of service if the morbid action be diffused, as in ordinary cases of insanity. It is chiefly of use where the disease is limited in extent, and particularly if it is attended by gross products, such as inflammatory lymph producing local tension, or tumours of the surface, or in the membranes. In injuries of the head it may occasionally be of service. Thus, in a somewhat doubtful case of fracture of the skull, the writer has seen it assist in marking out the line of the fracture. In disease of the inner table of the skull, when the pain of the head is widespread, it may help to localise the lesion. Wherever, therefore, there is the least ground, judging from the general symptoms, for suspecting that disease may exist superficially within the skull, percussion of the head should not be omitted; it may yield most valuable information, on which important local treatment may be based.

Clinical Records.

BRITISH HOSPITAL, MONTE VIDEO.

Case of Gastrotomy and Removal of a Dinner Fork from the Stomach.

Under the Care of Mr. L. A. FLEURY, Surgeon to the Native Hospital, Caridad, and Surgeon to the British Hospital, assisted by

Dr. YOURKOUSKI, Professor of Anatomy, and Surgeon to Native Hospital, and by Dr. E. A. LUCAS, R.N.

JOHN CHAMBERS, *æt.* 42; occupation a cook, presented himself at the hospital on July 10, 1880, and gave the following history:—

Two days previously, while trying to amuse some children by pretending to swallow a plated dinner fork, he accidentally let it slip out of his finger, and felt it passing down into his stomach. The foreign body at this time gave rise to no inconvenience, except slight nausea and vomiting, which occurred chiefly after taking solid food.

No operative treatment was attempted at this time.

On the 8th of the following September, after jumping off a low wall, he experienced a sharp stinging pain in the abdomen, and that night could distinctly feel the prongs of the fork through the abdominal walls. He came again to me on the 13th of September, and after a consultation an operation was decided on.

Operation, Sept. 14th.—The patient having been brought under the influence of chloroform, an incision 3 inches long, was made in the epigastric region along

the external border of the left rectus muscle at the point where the foreign body was felt; the skin and superficial parts of the muscle having been divided, after a short dissection the points of the prongs became visible imbedded in the muscular tissue. The operation at this point became more complicated, as each of the four prongs had to be separately dissected out, and the internal aponeurosis of the rectus, and the peritoneum divided. The stomach was now seen much displaced downwards, a circular incision was made into it round the fork which, after a little difficulty, was extracted. The edges of the wound were now drawn forward for about an inch and brought together by a continuous suture of carbolised gut, the internal sheath of the rectus was next closed by sutures of the same material, and the external wound by hare-lip pins, the wound was then dressed and a bandage applied round abdomen.

I may mention that the operation and dressing of the wound were conducted in accordance with Lister's antiseptic method.

The position of the fork in the stomach was from before backwards, the handle in the pyloric end and the prongs in the anterior surface of the cardiac, the curve of the fork was looking downwards and outwards.

15th.—Tongue furred; very little pain. Is allowed tea spoonfuls of iced water every half hour, and an enema of 2 ounces of beef-tea, with an egg beaten up in it every third hour.

10 p.m.—Quite quiet. Prescribed *pulv. Doverii*, gr. x., at bed time. Pulse 80; temp. 100; passes urine freely.

16th.—Slept fairly; feels strong, and is in good spirits. No pain over wound. Iced water and enemas as before. Gr. $\frac{1}{2}$ of morphia at bed time. Average temperature for day—maximum 99.2, minimum 97.8; average pulse, maximum 104, minimum 80.

17th.—As the patient was slightly restless, another half grain of morphia was given at 2 a.m., after which he slept well till 6.30 a.m., when another nutritive injection was thrown up. During the afternoon he was given two ounces of cool beef-tea by the mouth. Average temperature during day—maximum 99, minimum 97; pulse maximum 100, minimum 84.

18th.—Passed a good night, feels strong, has no pain. Enemas of beef-tea and egg at longer intervals. Beef-tea by the mouth in large spoonfuls every hour.

10 p.m.—Morphia at bedtime as before. No abdominal tenderness, except in immediate vicinity of the wound. Average temperature during day—maximum 99, minimum 97; pulse, maximum 100, minimum 80.

19th.—Not so well, had a bad night, and some pain in wound extending over epigastric region. Bowels were moved about 3 p.m.—a hard, clay coloured stool—felt great relief after this; continue his beef-tea. Enemas reduced in amount. Urine was passed freely, highly coloured, but no deposit. Morphia not required. Average temperature during day—maximum 100.2, minimum 98.6; pulse, maximum 98, minimum 84.

20th.—Some pain over wound. Changed dressings for first time, and removed two pins, the wound looked fairly healthy, but small sloughs at entry and exit of pins. Dressed antiseptically as before. Enemas discontinued. Average temperature during day—maximum 100.2, minimum 98.5; pulse, maximum 98, minimum 80.

21st.—Passed a very bad night, and still complains of pain. Bowels opened slightly—ordered an enema of castor and olive oil with \mathcal{M} .x. of tinct. opii at 4 p.m., with but little result. Tongue very foul—continue beef-tea, egg, and milk.

9 p.m.—Pain still continues. Pulse 104, dressings removed; wound emits a slightly offensive odour, and there is a small abscess at lower third of wound discharging pus. The remaining pins were extracted. The external wound had not closed, except at lower part of incision, and was gaping slightly. An abscess was discovered in the sheath of the rectus muscle, and about 2 ounces of foetid pus came away, after which he complained of no pain or tension. Wound dressed as before.

Average temperature during day—maximum 100.8, minimum 97.2; pulse, maximum 77, minimum 68.

23rd.—Improving—temp. 98.6, pulse 72. Antiseptic dressings discontinued, and linseed meal poultices applied every fourth hour. Free discharge of healthy pus, wound granulating from the bottom. *Diet*—Eggs, milk, beef tea, and a little soft bread in small quantities.

24th.—From this date he exhibited no bad symptoms of any kind. His temperature never exceeding 98.6, or his pulse 80, and all the functions of the body were performed normally.

October 1st.—Allowed to sit up, and got some solid food. Next day allowed out for an hour. Wound is nearly closed, and looks very healthy. Poultices stopped, and simple dressings used instead.

15th.—Discharged from hospital—cured.

Special.

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

INOCULATION OF CONTAGIOUS PLEURO-PNEUMONIA.—At the recent meeting of the Académie de Médecine on the 8th of September, M. Bouilly read a report on the inoculation of contagious pleuro-pneumonia. According to him, inoculation of the virus practised in the tail of the animal, was a sure guarantee against this disease. In concluding his report, M. Bouilly expressed the hope that one day he would be as successful in attenuating pleuro-pneumonia, as his colleague M. Pasteur had been in the cholera of fowls. Unfortunately, the very commendable and legitimate attempts of M. Bouilly to aspire to the fame of M. Pasteur are not likely to be crowned with success, at least, as regards the disease which is the ruin of many a farmer. On Wednesday last M. Leblanc took the liberty to oppose the assertions of M. Bouilly in round terms, and showed, by quoting a certain number of facts, that inoculation was of no benefit whatever in pleuro-pneumonia, and that its consideration was only a waste of time.

NITRATE OF SILVER IN SCIATICA.—Subcutaneous injection of nitrate of silver has been strongly recommended and frequently employed by M. le Dentu of the St. Louis Hospital, in the treatment of sciatica. The following is a case that succeeded in the hands of Dr. Greslon:—A woman, *æt.* 53, of a rheumatic diathesis suffered from all the classic symptoms of sciatica in the left leg, the whole member from the external malleolus to the sacro-sciatic notch was the seat of lancinating pain, which lasted a month. All the ordinary means being used but without effect, the patient consented to the subcutaneous injection of the agent in question. Five drops of a solution (1 in 4) was injected in upper and back of the thigh, at a point corresponding to the exit of the sciatic nerve. This injection was immediately followed by great pain, and an abscess formed giving exit to a teaspoonful of pus. Three or four days afterwards the patient was able to get up and walk about, all pain having left the leg. However, the point corresponding to the sciatic notch remained as sensitive as before, and another injection was practised which was not followed by an abscess, and in a week the cure was complete. This case is not only interesting from the rapidity of the cure, but also from the fact that the subject was rheumatic and consequently was unfavourable as to prognosis.

CURIOUS ACCIDENT.—A curious accident has been reported by a provincial doctor in the *Concours Medical*. A woman, *æt.* 32, six months *enccinte*, was occupied in feeding a cow which she held by a cord, when she received from the animal a violent thrust from its horns. Sent for immediately, the doctor found the woman in a hand barrow in a half sitting posture, and had to content himself by slipping her on to a bed thrown on the ground, for she declared it impossible for her to stir. When the clothes were cut open the gravity of the accident was revealed. The abdominal cavity was entirely exposed. At the lower part was to be seen the uterus thrown forward and slightly inclined to the left, a position which enabled him to touch the right round ligament. The great epiploon had almost entirely disappeared, what remained of it covered the superior border of the transverse colon visible in its whole length and occupying its normal position. On the right, a part of the small intestine issued from the abdominal cavity, and was of a brownish colour. On palpation the uterus contracted and the mother felt the movements of the child. The pulse was regular but small, and giving 96 pulsations to the minute. The loss of blood was slight. Before such a grave situation, M. Mignen thought it best to commence by extracting the fœtus, which was done by an incision made in the most projecting part of the uterus, but the child died two hours afterwards. The

uterus contracted energetically. Our *confrère* sought to unite by suture the different parts of the abdominal wall, but from the inferior extremity of the thorax to the anterior border of the pelvis, and from the superior right and left iliac spines to the false ribs, the wall had disappeared. Death took place thirty-six hours after the accident.

HYPERÆMIA OF THE LIVER.—M. Durand-Fardel calls attention in the *Revue Médicale* to the treatment of simple engorgement or chronic hyperæmia of the liver by *massage* or kind of friction allied to shampooing. This hepatic engorgement is characterised by a simple increase in the volume of the organ, and always terminating in resolution. The pain whether it be spontaneous or produced by pressure, shows itself at intervals, and can be absent altogether. The icterus is generally slight and more yellow than green. Against this affection, besides the use of the mineral waters of Vichy and baths, M. Fardel recommends the use of local douches on the hepatic region and the massage, at least, when the pain is not severe. The douche is given every two days and finally every day, the operation should not last more than ten minutes. As to the massage he describes it as follows:—The abdomen should first be rendered supple, and then the hand is passed by simple friction over the liver, the integuments covering that region are first rendered supple, and then the liver itself, until, as by a sort of kneading process the inferior border is reached, which is raised up by seizing it with the hand. It is needless to add that these manœuvres should be continued for a month at least, and exact a great deal of management and gentleness. Each time the patient experienced an alleviation of this disorder and a certain *bien-être*.

IRISH UNION HOSPITALS.

At a meeting of the executive committee held at the Hibernian Hotel, Dublin, on the 29th ult., Dr. Mayne in the chair, the following resolutions were proposed by Dr. Adrien, seconded by Dr. Holland, and adopted:—

1. That we tender to the *Lancet* the hearty thanks of Irish union hospital physicians, for the influential and thorough support which it has given to our movement.

2. That in consequence of the Queen's College opposition, an application be made to the leading Scotch licensing bodies for recognition, and that a deputation do proceed to that country for the purpose of concluding all arrangements.

3. That we strongly protest against the exclusion of provincial men from the witness-table of the Medical Commission, and we feel satisfied that public opinion will endorse this protest.

4. That we again urge all union hospital men, to unite as one man, a course which is all the more incumbent on them, after the gratuitous insults heaped on us in some quarters.

5. That Dr. Laffan be requested to bring under the notice of the Irish College of Surgeons, and subsequently, if necessary, under that of the General Medical Council, the irregularities which are constantly perpetrated in the various medical curricula, by certain interested parties in Dublin, who openly advertise for apprentices, to whom they pretend to allow sufficient time for lectures, &c., though such time is wholly insufficient to satisfy the regulations of the colleges.

6. That this meeting has heard with satisfaction from Dr. Moore, of Cavan, that it is an error to suppose that Irish union hospitals are not recognised, and the proofs he has adduced of such recognition not only by Irish, but by some English Bodies, shall be published if necessary by our hon. secretary.

7. That the thanks of this meeting be given to Drs. Hayden, Lyons, and Cruise, for their promises of support in the Royal University Senate, and that the attention of all union hospital men be directed to the attitude of some of the Queen's College Senators, whose hostility, if persevered in, should leave no alternative to every union hospital physician, who pretends to the possession of the slightest self-respect, but implacable hostility to the Queen's College Medical Schools.

8. That we call for subscriptions from all union men.

The deputation appointed to wait on the Royal University Senate, laid all the necessary documents before that body,

and eloquent speeches in favour of their claims, were made by Drs. Hayden and Lyons.

The Senate has, however, been too pressed with business, to proceed immediately with the consideration of the application, and such consideration remains over for the present.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR

Is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6

.. IF PAID IN ADVANCE 1 1 0

* Post-office Orders and Cheques to be drawn in favour of—

A. A. TINDALL, 20 King William Street, Strand, London, W.C.

A. R. JACOB, 3 Molesworth Street, Dublin.

Agents for Scotland:—

MACLACHLAN and STEWART, South Bridge, Edinburgh.

A. and W. STENHOUSE, Hillhead, Glasgow.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLIAMS and ROGERS; Philadelphia, by Dr. BRINTON post free in advance, 5½ dollars (£1 2s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order

ADVERTISEMENT SCALE.—Whole Page, £5 0s. 0d. Half Page £3 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth Page, 12s. 6d.

Small Announcements of Practices, Assistances, Vacancies, Books, &c., of seven lines or under, 4s. per insertion; 6d. per line beyond. Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, OCTOBER 12, 1881.

THE SOCIAL SCIENCE CONGRESS.

THE meeting of the Social Science Association, which occupied the attention of the Dublin public last week, deserves to be recorded as a highly successful *reunion*, and as resulting in a substantial accession to the strength and influence of the organisation. Its success, indeed, largely exceeded public expectation, and the impression left on everyone's mind is one eminently favourable to the usefulness of the Association as an organisation for educating society upon most questions. Each of its departments was presided over by men whose qualification to lead the discussions upon their own speciality was open to no question; and the aggregate assembly was under the leading of the Lord Chancellor of Ireland—a man whose high name, no less than his oratorical and administrative ability, gave dignity to the meetings and inspired confidence in the conclusions arrived at.

The Public Health Section—with whose doings we are

specially concerned—met under the presidency of Dr. Cameron, M.P., and its deliberations were chiefly concentrated on four subjects, than which none more interesting or important could have been selected. State Supervision of Hospitals, Notification of Infectious Diseases, Dwellings for the Working Classes, and the Abuse of Stimulants in Irish Workhouses—these were the subjects which engrossed the attention of the Section, in which the attendance was—usually—large, and the debates lively and well argued.

The Public Address of the President himself we print in abstract to-day. It was devoted to a *résumé* of the investigations of Pasteur and his eminent *confères*, in reference to the germ origin of external diseases, and the prevention of those diseases by inoculation with the “attenuated” virus of the same disease. These experiments have been reported from week to week in our columns, and are now put together in narrative form by Dr. Cameron, being thus invested with an interest for the general public almost romantic in its character. The propriety of supervision of hospitals by the State was worked out by Mr. Burdett, who certainly established a very strong case for Government intervention in the management of London hospitals. He pictured truthfully the monstrous misuse of charitable funds which occurs under the unmeaning and objectionable autocracy of a “Treasurer” and his staff of insubordinate lady nurses; and he appealed, on behalf of the sick poor and of the benevolent supporters of these institutions, against a perpetuation of the existing most improper system. The debate which followed made it clearly obvious that these abuses which admittedly exist in London in their highest development are by no means confined to the great city. The enormous establishment expenditure in certain Dublin hospitals, the misallocation of charity by the Dublin Sunday Fund Council, and the utter inefficiency of the Dublin Hospitals Board as a check upon such abuses, were all the subject of earnest discussion.

The Notification of Infectious Diseases took the chief place in the proceedings of the Section, and derived special interest from the imminency of a Bill in next session of Parliament to force the physician to send notice to the sanitary authority of every infected case he sees. The expediency of imposing this duty upon him was maintained by Dr. J. W. Moore, and by Mr. Michael, Q.C., and Dr. Cameron, of Dublin. A modification of the proposal was advocated by Dr. Stewart Woodhouse. Space does not permit us to reproduce the reasons set forth by these gentlemen, which must be already familiar to the readers of this journal. Substantially the line of argument was:—1. The concealment of infective disease is a rife, and is disastrous in its effects upon public health. 2. It can only be effectually checked by the agency of the physician. 3. Notification by the physician would not be really either irksome or injurious to his practice, but if it were, he must be content to suffer the loss and inconvenience for the public weal. The duty of contending against these propositions was undertaken by Dr. Jacob, who opened the debate. He insisted, in reply:—1. That, however desirable it might be that infective disease should be speedily detected, the result of making the physician the agent for such detection would be to cause him to be

excluded from the patient, and thus to imperil life and increase concealed disease. 2. That, in equity, the responsibility to notify to the sanitary authority should rest, so to speak, on the proprietor of the *nidus* of infection, and not on any other person. 3. That, to impose such duty on the physician would be to throw the practice into the hands of quacks and dishonest practitioners, who would be employed on the understanding that they would *not* notify, and who could not be either detected or punished for their ill-doing. The anti-medical side of the question was represented by Mr. Hastings, M.P., and Mr. Gray, M.P.—the sponsors of the English and Irish Bills of last session, by Dr. Norwood, of the Dublin Corporation, the Registrar-General for Ireland, and the Town Clerk of Jarrow; while the inexpediency of imposing such duty on the physician was maintained by Dr. Chaplin, President of the Irish College of Surgeons, Dr. Davys, Coroner for the County, Miss Downing, of London, and other speakers. We regret, however, to have to confess that our profession was but weakly represented, and that that unhappy lethargy about public matters—even those which closely involve their own interests—which characterizes Irish doctors generally, was manifested in the debate.

The result of the debate may be described in chess language as a "stale mate," neither party taking anything by their motion save the gain arising from a discussion of the question. A noteworthy point is that while the anti-medical party rested their case greatly upon the satisfactory working of the system in the English towns in which it is in force, not one of them offered any evidence whatever of the fact. They quoted the approval of the system by medical officers of health (whose approval is a matter of course, seeing that the system saves them and their corporations a good deal of trouble and much money), but they did not tender any proof that the practitioners in those towns worked the system willingly, or that the zymotic death-rates had fallen in such places since the Acts came into operation; or that the number of deaths in which no physician attended was not increased in such towns; or that the law had been successfully enforced anywhere against recalcitrant practitioners. Nor did they meet in any way the argument that, supposing the law to be effectual in England, it is quite unsuited to the medical system and sanitary arrangements of Ireland.

The subject of "Dwellings for the Working Classes" was brought forward with great eloquence and force by the Recorder of Dublin, by the superintendent medical officer of health for the city, and by Mr. Spencer, secretary to the Sanitary Association; and by these gentlemen a state of things in a Christian country and in a civilized age was divulged. The only question capable of dispute was how the evil of squalid houses might be met, and there was a consensus of opinion that a large expenditure was inevitable, but that it might be expected that such outlay would be recouped by actual income as well as by improved health. We hope to analyse the papers next week.

The subject of "Stimulants in Irish Workhouses" was brought under notice by Dr. MacDowel Coogrove, of Dublin, and Dr. Norman Kerr, of London. Every subject which touches upon temperance seems fated to

intemperate and illogical discussion, and these papers were no exception to the rule. Dr. Coogrove's argument resolved itself into a statement of the uselessness of alcohol as food, and it was followed up by the usual exhibition of flippant dogmatism by the organising secretary of the Dublin Temperance Association. Much that was valuable might have been said upon the Parliamentary return of stimulants lately issued upon the motion of Mr. Whitworth; but, instead thereof, the audience was favoured with the decidedly commonplace denunciations of alcohol drinking to which it is so well accustomed.

This meeting has, we think, greatly raised the Social Science Congress in Irish estimation. It has proved to demonstration that the organisation is not, as scoffers have said, an aggregation of cackling doctrinaires, but rather an assembly of earnest and well-informed people whose interchange of opinion cannot fail to yield good fruit.

THE INTRODUCTORY ADDRESSES.

THE commencement of a new session invariably brings with it the delivery of a series of addresses, the number of which is dependent each year on the aspirations and other temptations to oratory on the part of gentlemen holding appointments on hospital staffs; or it is governed in a great measure by the special circumstance favourable to publicity connected with the administration of different institutions. On the uselessness of opening addresses based upon the old worn-out model of mutual admiration, we have already delivered our opinion; but it remains for us, notwithstanding, to note the fact that the commencement of the 1881-2 session has been inaugurated after this manner at several hospital medical schools, metropolitan and provincial; and to give some idea of the lines pursued by the speakers. In many instances it would seem that the skeleton address we published on September 28 has been rigidly adopted by writers of introductory; and we have been gratified by the receipt of a letter from one gentleman in the provinces, who, warmly thanking us for the assistance rendered him in his labours, demonstrates his indebtedness by enclosing a copy of the address actually delivered by him to the students of a Northern school, and which has evidently been framed on the plan suggested in our columns. Doubtless this outspoken admission might find many imitators in all honesty; but it is enough to prove to us the justice of our remarks on introductory addresses, and also the accuracy with which we were able to forecast the immediate future in regard to them. It is, however, pleasant to be able to feel that this autumn it is not every address that is a mere hash up of well-worn utterances, and that there are besides the lengthy and weary speeches, some that bear the stamp of a fine originality, and the healthy flavour of a newness wholly new. Anticipating, as we did, that the universal theme of opening lecturers would be the dignity surrounding the future practitioner, and the nobility of his calling, we could not fail to welcome the practical and telling address in which Dr. Vivian Poore hailed

new students to University College Hospital. Abandoning the useless but seductive admiration yielding which formed the staple of his fellow-orators' themes, he ventured on the bold plan of attacking an evil and advocating its remedy, to just those very persons who may be supposed both to be most interested in its reform, and to be likely to move for its abatement. Dr. Poore condemned, in severe and well-deserved terms the rapid growth of already excessively over-numerous technical terms employed in medical science. According to him, the New Sydenham Society's "Dictionary of Medical and Scientific Terms" may be expected to contain upwards of three hundred thousand names, and to these the possible additions exceed all power of estimation. This in itself is bad, and arises chiefly from a universal unwillingness to apply to the purposes of medicine the ordinary language of everyday life. Nor does the evil rest at this, for with the intention of concealment in words comes also a desire to further complicate by the manufacture of new terms by which to indicate well-known conditions, and an all too prevalent striving after the use of words whose length is oftentimes their sole claim to preference in the description of symptoms. Further, and as directly bearing on this subject, Dr. Poore urged the necessity for an international scientific language, a necessity that received a most practical demonstration at the sittings of the recent Congress in London. Such an address, directed to a definite object, and dealing with it after a thoroughly practical and understandable fashion, is calculated to be of some considerable service to students—not alone by showing them a very gaping pitfall right beneath them, but also by suggesting out of itself wider and vaster questions bearing directly on the welfare of the profession they have engaged to follow.

At Westminster Hospital Dr. Allechin read an address prepared by Mr. Bond, who was unfortunately prevented by illness from being himself present. In it the medical curriculum was described, and the openings by which young men could hope to enter into remunerative practice, "specialism" proving a subject on which the lecturer dilated at some length. Direct representation in the Medical Council of the general profession, general vindication of the dignity of the medical calling, and a reference to recent vivisection legislation, formed the topics of the remainder of the address, which exhibited no remarkable features of novelty in any way.

Mr. Pemberton addressed the new students at the Birmingham School on the means present in Birmingham for the cultivation of medical science. After sketching the history of the two hospitals, the General and the Queen's, in the town, the lecturer proceeded to deal with the means by which it might be possible to amend the present scheme of medical education. He complained that the majority of "duly-qualified" medical men, when first they entered on their career, were painfully ignorant of those practical matters which were much too commonly undervalued, even by those about to be entrusted with the preservation of human life. He advised students to make frequent and constant use of post-mortem rooms, and wards, and to neglect no means open to them of obtaining the utmost

possible practical acquaintance with the details of their profession. In an impassioned manner he deprecated the insensate opposition raised against vivisection by ignorant enthusiasts; and among other institutions devoted to medical training in Birmingham, mentioned also the new Mason College as a place where the preliminary scientific work may be thoroughly well studied. A rattle through history, and a modicum of cheerful advice concluded a serviceable, even though not original, address.

The opening of the Medical Faculty of University College, Liverpool, was inaugurated by an address from Dr. Oliver Lodge, professor of experimental physics to the college, which, as might be supposed, dwelt rather on the value and means of obtaining a liberal education than on any distinctly professional topic. Subsequently Lord Derby addressed the students in a way to show the estimation in which he, at least, held the calling of medicine, urging on all who were then intent on pursuing the path through life marked out by the course of a professional career to keep ever prominent the credit of the body to which they were attached.

Sheffield students were addressed by Mr. E. Skinner, lecturer on anatomy; and at the Durham University School of Medicine, Newcastle-upon-Tyne, Dr. Murphy delivered an address.

In London, Middlesex students received from Dr. R. Douglas Powell, physician to that hospital, a cordial welcome to the institution, and an assurance that they were about to engage in the preliminaries of a profession second to none for the elevated position of its members. He then sketched out the lines on which students of disease should proceed, and concluded by advice to those about to enter into practice.

At St. Thomas's, Dr. Bernays, lecturer on chemistry, opened the session on October 1st with an address devoted chiefly to the methods of study; and at St. Mary's Mr. Field welcomed the new-comers. Mr. Field approved of introductory addresses, and then proceeded to regulate the fees to be received by medical men, according to a fixed scale; and dwelt on the question of hospital support at some length. He spoke also on legislation, condemned the anti-vivisection agitation, and some special institutions. He concluded by a panegyric on the nobility of medicine. Sir John Lubbock was the orator at King's College; and Mr. Warrington Haward at St. George's.

THE CASE OF PRESIDENT GARFIELD.

WHEN referring to this subject some few weeks since we purposely refrained from passing an opinion upon the treatment pursued until the result of the autopsy was known and the excitement had calmed to the logic of facts. The press of America, both lay and medical, now discuss the case with the additional light thrown thereon by the post-mortem; and though little has been adduced to the knowledge already in our possession, yet it is satisfactory to read that by the general verdict of the profession "the President received all the aid which medical science, intelligently applied, could furnish." It is held that looking back upon the case

by the light of the autopsy it is impossible for anyone to say that a different line of treatment than that pursued would have saved the patient's life; and further, that medical art prolonged a life which otherwise might have ended in a few days. No doubt, a special knowledge of the case gave to the medical profession in America early assurance that a fatal issue was to be looked for; and in the further details of the case to which we look forward, explanation will doubtless appear as to the circumstances under which so little of that assurance was expressed in the telegrams which reached this country. As regards the secondary affections by which death was brought about, including septicæmia with its abscesses—or pus cavities, as they were called—and hæmorrhage, from a blood-vessel lying in the track of the missile; all these constituted the ordinary train of phenomena which are to be expected and looked for in a gun-shot wound such as General Garfield's, and so long as the bullet remained unwithdrawn. According to the dictum expressed long ago by Hennen, in cases of gun-shot wound of the abdomen, "the search for extraneous bodies, unless superficially situated, is altogether out of the question." The circumstance is recorded by him, and by others long before his day, that "balls sometimes remain in the cavity of the abdomen during life;" and the fact that in very rare instances a bullet that had penetrated the abdomen became evacuated by the bowel was also well known to military surgeons. Such instances, however, were so exceptional as to be excluded from account in estimating the danger attending wounds in that region. When, therefore, the fact is noted that the wound of the President had the additional complications of fractured rib and body of a vertebra, the utterly hopeless nature of the injury from the very moment of its receipt becomes evident.

In reference to this case, the *New York Medical Record* is of opinion that "in attempting to reconcile the diagnosis of the case with the microscopical revelations, we are met with surprises in several directions. Notwithstanding the great amount of careful and intelligent study of the case, the precise course of the ball was not made out previous to death. Considering the parts involved, the strange deflection of the missile, and the extent of its penetration, any satisfactory and safe exploration would have been impossible. Indeed, the opening through the body of the first lumbar vertebra appears to have been discovered accidentally, as was also the ball itself. The missile was really found in the mass of intestines and annexa after removal of the latter from the body. The supposed track of the ball proved to be nothing but a burrowing sinus connected with the fractured eleventh rib. The large pus-pouch under the liver was evidently due to the same condition, becoming converted into a closed sac by unequal healing in the course of the sinus." As remarked by our contemporary, "there were peculiar difficulties in the case, and they of a nature best appreciated by all who, themselves, have had experience in the treatment of gunshot wounds; and however greatly we may regret that, in view to the great public importance of the case, a correct opinion as to the course of the ball was not

made at the beginning, and was not proven at the end, it is quite difficult to see how the error could have been avoided. There were no symptoms during life to point to the locality of the ball."

There are several lessons of very great importance to be gathered from the case of the late President. Among them is the absolute necessity in similar instances of giving at once a definite assurance to those most directly concerned as to the extent of imminent danger to the patient, and as to the precise circumstances which counter-indicate manual interference for the withdrawal of a missile, whether fired by the hand of an assassin, or otherwise received.

CONSULTING WITH HOMŒOPATHS.

It is with a feeling of profound concern that we chronicle an event, the evil consequences of which to legitimate medicine, it is impossible to foresee, and the blame for which must assuredly attach to the indiscreet and too ingenuous champions of indiscriminate liberalism who recently invited the union of scientific medicine with irrational and dogmatic nonsense. We refer to the decision arrived at by a small majority of the Lancashire and Cheshire Branch of the British Medical Association, to the effect that it shall be no longer considered necessary to refuse to meet homœopathic practitioners in consultation.

At the time when Mr. Hutchinson gave expression to his curious views on the ethics of medicine, most of those who felt how seriously he had strayed from the limits of legitimate toleration, elected to regard him and the other lights of the profession who agreed to think with him, as good naturedly advocating a measure of relief towards a class they considered to be somewhat overweighted in the race for professional emolumenta. It was, in a way, generous to recognise that the fact of qualification in medicine should entitle a man to the sympathy of every brother practitioner, notwithstanding that errors of the grossest kind should be common occurrences in his daily routine. It was, we say, generous on the part of Mr. Hutchinson to advocate freedom of intercourse with homœopaths, generous that is to the homœopaths; and especially so, since the chances of Mr. Hutchinson being called to embody in his own person the theory so pleasantly advanced, had all the fanciful elegance of improbability. But did Mr. Hutchinson, we wonder, or did Dr. Bristow, or did Mr. Barrow, reckon on the wholesale effect that would be given ere long to the moral they conveyed in their addresses. We like to think well of all men at all times, and, for this reason, in the absence of any direct proof, we cannot imagine that the dark, humiliating picture of the general medical profession hand and glove with the homœopathic fraternity, ever presented itself as a possible consequence of their performance to the gentlemen who have dealt the worst blow to their profession that it ever received from one of its own members. What, we ask, in despair almost, if every branch society of the British Medical Association, realising the fact that men eminent throughout the world for knowledge and breadth of intellect, have passed the word for a bridging over of the gulf,

hitherto regarded as impassable, separating medicine from all that is not medicine, what then is become of the dignity, and the glory, and the honour, that glowing introductory orators have but just declared to be inseparably connected with the profession and practice of medicine? We dare not hope that the *morale* of medical men, ununited body as they are, will support them against the tide loosened on them by the miserable apostacy of a few of their brethren; nor can we anticipate that the one errant branch in the north will long remain alone affected by the *auri sacra fames*, which is, perhaps, in chiefest part to blame for the wretched resolution they have approved. And then, what is to follow? The wrecking of the Association is, of course, assured, if it once either actively or passively assents to the proceeding of a section of its members. There are, we trust, a few good men of honest reputation, of steadfast faith in the nobility of integrity, and endowed with a hatred of sham, who will, to the end, protest against the miserable fraud that must be perpetrated each time that a consultation (save the mark) is assented to between a pretender—who ranks symptoms as supreme, who reckons the efficacy of medicine apart from all question of its presence, and who refuses sanction to all scientific proceedings in the shape of treatment—and a regular practitioner. The whole thing is a monstrous farce; and that any men of hitherto honest reputation, should openly and willingly signify a determination to enact it at each available opportunity, is the most humiliating, the most degrading consequence that has yet followed the ill-judged, ill-timed, and ill-fraught, advocacy of universal tolerance delivered at Ryde.

How to meet the new and fatal spirit is the problem that most distresses us.

Notes on Current Topics.

Epidemic Fighting.

THERE is at present in the country a sort of epidemic of prize fighting, the extent of which has grown sufficiently to attract the notice of the Home Secretary to the phenomenon. His attention has been directly drawn to several instances in which serious injury has been inflicted during these brutal encounters, on one or other of the combatants; and all persons anxious to see no hindrance opposed to the continued advance of this country along the path of civilisation and culture will not hesitate to endorse the emphatic strictures passed on the degrading pastime so inappropriately designated "sport." The number of fights between men ostensibly met for a friendly encounter at boxing is appreciably on the increase, and in many cases damage is inflicted which may permanently affect the health of the recipient. The details of some of these combats are fit to grace the records of a hundred years ago; and at Coventry, within the last week, medical evidence as to the death of a man killed in a prize fight ran as follows:—Deceased's "face and eyes were much swollen and bruised; the chest and sides much bruised; three ribs were broken, and blood was oozing from his mouth and nose, the bones of which were completely smashed, and the left hand was

much swollen and contused. Death was caused by extravasation of blood on the brain, occasioned by injuries received at the prize fight." We submit that when such occurrences as here described are being almost daily witnessed in some part of the country, it is high time that energetic measures should be adopted for suppressing what bids fair to become an acute mania for ruffianly sport. It is to be hoped that measures now being taken to this end may be successfully carried out, and result in the banishment from this country of one of the worst and most barbarous bequests from our less civilised ancestors.

Indian Medical Items.

In future hospitals for British troops in the Presidency of Bengal are to be organised and conducted as station hospitals on the principles laid down in the Regulations for the Medical Department of Her Majesty's Army, dated War Office, Nov. 1, 1878. The system will be introduced at once at forty-eight stations, where the present buildings are adapted for the purpose.

A return has been submitted by the Surgeon-General of Her Majesty's forces showing the sickness, mortality, and invaliding in the British troops serving in the Madras Presidency in 1880. The total of admissions was 14,084, and the deaths in hospital and out of hospital amounted to 100 against 173 in the previous year. The total of men invalided was 238 against 467 in 1879. The figures for the year 1880 are very favourable when compared with 1879, and the comparatively small number of deaths from "all causes" shows that the health of the troops in the Presidency was exceptionally good.

The *Times of India* believes that yet another blow has been aimed at that long-suffering department—the Indian Medical Service. Notwithstanding the radical changes of April 1 of last year, by which the medical service was grievously injured by the Secretary of State, it would appear that this time it is the hand of the Government of India by which a fresh wound is to be inflicted, for it is said that a despatch has gone home recommending what are termed "extensive reforms," and being based on the semi-amalgamation of the Indian Service with the British, as shadowed forth in our last issue. It would appear that everyone has been called upon to give his opinions on the future of the Services except those most intimately acquainted with their practical working. Commanders-in-chief, members of Council, chief commissioners, and lieutenant-governors, figure as doctoring the doctors; but with two or three solitary exceptions the doctors do not seem to have had anything to say on the matter. When, to obtain some statistical information it was found positively necessary to refer to the department, the Surgeon-General in Bengal appears to have been addressed; but it was totally ignored that in Madras, and in Bombay also, there exists a medical department having necessarily interests and employments differing from those in other parts of India.

Hackney Smells.

It appears that the inhabitants of Hackney have for a period been suffering from the existence in their midst of constant evil smells and exhalations, the origin of which has not yet been satisfactorily determined. The medical

officer for the district, Dr. Tripe, has again and again had his attention directed to these exhalations, but no action has yet been taken either by the local or Metropolitan boards to put an end to the nuisance. Several letters have appeared from inhabitants of Hackney, who not unnaturally loudly complain of the danger they suffer from the ill-smelling exhalations they are compelled to breathe day after day. From certain of these epistles we should infer that a good deal of the mischief is due to the building of houses on "made" foundations, the material of which the subsoil consists being largely made up of decomposing refuse from all manner of situations. In other towns, this has been found to be the cause of even serious outbreaks of illness, and there is a good deal to point to a similar origin for that which has occurred in the Hackney district. In some places, however, open ditches, serving in part as drains, are distinctly mentioned; from these it need hardly be suggested, the seeds of disease may with ease and certainty be disseminated; and judging generally from the complaints that have been published, there is every reason for insisting on a searching investigation into, and a speedy removal of, the causes which are to blame for the present uncomfortable state of affairs.

The Dangers of Pork.

FROM time to time we hear of epidemics from the incautious use of improperly cooked pork which has been infected with the trichina larva, and it had been assumed that this was the chief danger attendant on the consumption of the flesh of the pig. The Leicester police court, however, was on Friday the scene of an inquiry, in the course of which facts were made known in the face of which consumers of pork pies may well feel called upon to exercise especial caution in future dealings with purveyors of these delicacies. The case referred to was a charge brought against a Leicester butcher by the Town Clerk, the offence being that prisoner had on his premises two tons and a half of hams, bacon, and beef, utterly unfit for human food. The details afforded during the trial of the manner in which decomposing and putrescent flesh is regularly prepared by a system of elaborate high spicing, to meet the requirements of connoisseurs in pork pies is instructive, but by no means edifying reading, and should be carefully perused by all accustomed to indulgence in the articles for the manufacture of which all the savoury but ill-savoured material was destined prior to its capture. It is satisfactory to know that a lesson has been forcibly taught to the defendant in this action, the bench having sentenced him to imprisonment, without hard labour, for two months; and it may well be hoped that this will convey a warning to all other purveyors of pork pies, if there be any, who are not in the habit of being over particular about the source and condition of the materials out of which their stock in trade is composed. In the public interest we congratulate Leicester in the possession of a bench of magistrates so clearly alive to the hygienic importance of a pure food supply.

Hospitals and the State.

AN important communication was made to the Health Department of the Social Science Association by Mr. H. C. Burdett on the subject of State supervision of hospitals, an abstract of which will be found in another part of our present issue. We would specially commend this for careful consideration as dealing with a question which from the constantly growing pressure on existent accommodation in hospitals must sooner or later come prominently to the front. Mr. Burdett's extensive experience in hospital work and management entitles him to speak with special emphasis on a question like this, and we feel sure that a consensus of opinion will follow his conclusions presented in the abstract of his paper.

The New Scheme of Education and Examination of the Irish College of Surgeons.

THE Council of the College has, we learn, appointed a deputation to wait on the Chief Secretary for Ireland and afford information and explanation respecting the New Scheme. Sir William Harcourt, in whom is vested the authority to approve of the abrogation of old bye-laws, which is necessary before effect can be given to the Scheme, is still absent from home. Meanwhile the Council has made arrangements to enable students who are now commencing study to proceed under the old or the new system, as circumstances permit. If anything should prevent the enforcement of the New Scheme, students will proceed as heretofore. If the New Scheme becomes law, they will be obliged to adhere to its provisions, but will have credit for their preliminary examination and for the lectures entered for under the old system.

Stimulants in Irish Workhouses.

A PAPER on this subject was read in the Public Health Section of the Social Science Congress, at Dublin, by Dr. MacDowel Cosgrave. He stated that during 1880, £11,845 8s. 7d. was spent on stimulants in the Irish workhouses, forty per cent. of the sick receiving them. The cost per head varied from 9½d. in Ulster to 3s. 3d. in Connaught. In the Dublin Unions it averaged 2s. 10d. per head. Stimulants were given to attendants in at least 76 of 163 Irish unions. The amount of stimulants consumed seems, on the whole, to be decreasing; but in some unions it is increasing. In the South Dublin Union the rate per head has fallen, during the last five years, from 1s. to 9½d., whilst in the North Dublin Union it has risen from 1s. 6d. to 1s. 9d. The author thought that stimulants cannot be used as food, as their cost would be excessive, to say nothing of the uncertainty of their utility. One imperial pint of Guinness's stout would only be equal, as food, to rather less than five ounces of sugar. Also 3½d. worth of bread is equal, as a force producer, to 3s. 4½d. worth of stout, estimated at its highest possible value. Alcoholic drinks are probably used as medicines, although they are paid for as other medicines are. But in the majority of cases alcohol diluted with water would be just as efficacious, and it would be cheaper, safer, and less attractive. The experience of any unions which may diminish the amount of stimulants used tends to show that it has

resulted in an increase of health. Many English unions show this. In Ireland there are not yet many examples to argue from, but those we have here are against the use of stimulants. If the return of the number of inmates, deaths, and costs of stimulants in the Irish workhouses be granted annually, we shall soon have sufficient ground for drawing more positive conclusions. In the South Dublin Unions the death rates for the past five years were 67, 69, 54, 55, 37, whilst the cost of stimulants per head was 2s., 1s. 5d., 1s. 2d., 1s. 1½d., 9½d. In the North Union the corresponding figures were 65, 76, 72, 86, 97, and 1s. 5d., 1s. 2d., 2s. 1d., 2s. 5d., 1s. 9d.

The Penalties of Milk Adulteration.

AT West Hartlepool two heavy penalties have been inflicted by the county magistrates for milk adulteration. In the first case a farmer, charged for the third time with the offence, was fined £50 and costs, or three months' imprisonment. In the second the fine was £10 and costs, or six weeks' imprisonment. If magistrates would more generally treat persons convicted of milk adulteration with similar justifiable severity, the dishonest practice would probably not continue to so great an extent as it does.

Sickly Children Dependent on the State.

A PAPER under this name was read in the Public Health Section of the Social Science Congress, at Dublin, by Mrs. Morgan John O'Connell. It attempted to arouse public opinion to investigate into the case of the numbers of scrofulous pauper children, sickly rather than actually sick, and offered suggestions for raising their health standard. A few facts concerning the extreme prevalence of the scrofulous condition among the Irish poor having been adduced, medical views on scrofula were next commented upon, and it was discussed why the special hygienic measures recommended in text-books are not applied to strumous pauper children in Ireland. Quotations from information bearing on the subject received from England and America were made, and a few plain suggestions were offered as to the creation of sea-side homes near Dublin with affiliation to existing hospitals, use being made of Count Moore, M.P.'s, Afflicted Persons Act for sending pauper children to such places. Suggestion of sisters of charity for Catholic, and late Mrs. Sullivan's organisation for Protestant sick children dependent on the State were also considered.

The Netley School.

THE forty-third session of the Army Medical School was opened at Netley on Monday, the 3rd instant, by an introductory address from Professor F. de Chaumont, F.R.S. The class for the winter is formed of twenty-four surgeons on probation for the Army Medical Service, and ten surgeons on probation for the Indian Medical Service, all of whom were successful in the competition for appointments in August last.

A REPORT by the medical men on the spot states that 77 per cent. of the cases in the diphtheria epidemic in the province of Oral in Russia proved fatal.

Lecture Attendance in the Queen's Colleges.

IN the report of the President of the Galway College which was recently presented to Parliament, he says:— At the present moment, special attention is directed to the question of the value of the lecture system in medical education. Now, in this college, a daily roll-call has always been in force in every class, and class-examinations are frequently held. A daily class-examination is held in the class of anatomical demonstrations, and a weekly one in physiology; and no credit is given for attendance when the answering of the student evinces inattention and inadequate study of the subject. The class certificate shows not merely the payment of a fee, and the entry of a name on the class-roll, but is a guarantee of continuous study of the subject on the part of the student during the entire session. While a reform of the well-known abuses of the lecture-system, now under discussion, has been only partially secured by changes in the rules of a small number of medical institutions, the system of roll-call and class examination adopted in this college has avoided the evil from the beginning.

Dr. Hayden, of Dublin.

SINCE our last issue this much-esteemed member of our profession has been stricken down by pneumonia of alarming severity. We understand that on Saturday week he experienced a chill, and on Sunday, Monday, and Tuesday became steadily and seriously worse. Drs. C. Nixon, Lyons, M.P., Cruise, and Banks were called into attendance, but, notwithstanding their efforts, the symptoms increased in severity, until, on the early morning of Saturday, the patient seemed moribund. Happily, a marked improvement then manifested itself, and the change for the better has been maintained up to the time of our going to press.

We earnestly trust that we may be able in our next issue to report convalescence.

Dr. McClintock, of Dublin.

THE improvement in the health of Dr. McClintock, which we reported last week is, we are glad to say, maintained, and substantial progress is being made towards recovery, which we hope may be speedy and complete.

Change of Address of the General Medical Council.

THE offices of this Council, where English and Welsh practitioners and students must be registered, have had their number changed from 315 to 299 Oxford Street, in consequence of a renumbering of the street which has taken place.

THE first meeting of the Ophthalmological Society for the current session will be held on the 13th inst.

PROF. MORRISON WATSON, of the Owens College, Manchester, is a candidate for the chair of Human and Comparative Anatomy at the University of Oxford.

THE Royal Microscopical Society will meet to night, at 8 o'clock, when a paper on Multiple Staining of Animal

and Vegetable Tissues will be read by Mr. B. Willis Richardson, F.R.C.S.I.

THE Queen has conferred the Victoria Cross on Surgeon Major Edmund Baron Hartley, for conspicuous gallantry displayed by him in attending the wounded, under fire, at the unsuccessful attack on Moirossi's Mountain, in Basutoland, on the 5th June, 1879.

IT has been finally decided that Sir William Muir, K.C.B., who has held the appointment of Director General of the Army Medical Department since 1874, shall retire from office on the 1st of April next, and that he shall be succeeded by Surgeon General T. Crawford, M.D., principal medical officer in India.

THE death is announced of Sir John Musgrove, Bart., president of St. Thomas's Hospital, in his 89th year. The deceased gentleman was an alderman of London from 1842 to 1872, sheriff in 1843, and Lord Mayor in 1851 when, at the opening of the Great Exhibition, he was created a baronet. The baronetcy becomes extinct.

AT a meeting of the Committee of Knocknadona Dispensary District, Lisburn Union, it was stated that they had advertised for a medical officer in the room of Dr. Johnston, resigned, yet no applicant had come forward. Another advertisement was ordered to be published; and in the event of there being again no candidate, a special meeting of the guardians will be held to reconsider the salary to be paid.

AMONG the French troops in Tunis, sickness is said to be increasing. Camp beds are insufficient; and many of the sick are said to be lying on straw, and dying without succour. According to returns, however, furnished by the Board of Health, the rate of sickness to strength of troops in Tunis is 4·83 per cent., in Algeria 4·82, France 4·30. The resources of the sanitary service are declared to be perfectly adequate.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population, were—Plymouth 13, Newcastle-on-Tyne 15, Sheffield 15, Portsmouth 15, Brighton 15, Leeds 16, Sunderland 16, London 16, Dublin 17, Edinburgh 17, Birmingham 17, Wolverhampton 17, Glasgow 18, Nottingham 18, Norwich 18, Bristol 18, Oldham 19, Leicester 20, Salford 21, Bradford 21, Manchester 22, Liverpool 22, and Hull 24.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 24, Bombay 28, Madras 37, Paris 21, Geneva 10, Brussels 19, Amsterdam 19, Rotterdam 14, The Hague 18, Copenhagen 19, Stockholm 15, Christiania 10, St. Petersburg 38, Berlin 21, Hamburg 19, Dresden 19, Breslau 27, Munich 26, Vienna 21, Prague 26, Buda-Pesth 30, Rome 29, Alexandria 47, New York 37, Brooklyn 35, Philadelphia 25, and Baltimore 36. No returns have been received of Naples, Turin, Venice and Lisbon.

THE Gresham Lectures on Medicine will be delivered by Dr. Symes Thompson at the Gresham College, Basinghall Street, on the 11th, 12th, 13th, and 14th inst. The subject for the present series is the Nervous System, which will be treated of under four headings:—Mind and Matter, Involuntary and Reflex Nervous Action, Nerves of Special Sense, Results of Defective Nerve Action. The lectures commence at 6 p.m. each evening.

IN three of the principal cities of the United States the rates of mortality have been very high for some time past, and according to the latest official returns there appears to be no immediate prospect of more healthy times. Last week, for instance, when the death-rate was only 16, 17, 17 in London, Dublin, and Edinburgh respectively in New York, Baltimore and Brooklyn, it was 37, 36, and 35 per 1,000 of their populations. Diphtheria and scarlet fever would seem to be the principal factors in this excessive death-rate in two of the three cities, diphtheria and typhoid in the third.

FROM diseases of the zymotic class in the large towns last week scarlet fever showed the largest proportional fatality in Hull, Bradford, Edinburgh, and Nottingham; no fewer than 225 fatal cases of this disease have been recorded in Hull during the past thirteen weeks, of which 28 were registered last week. The 27 deaths from diphtheria included 12 in London, 8 in Glasgow, and 2 in Portsmouth. Fever, principally enteric, showed the highest death-rate in Leicester, Newcastle-upon-Tyne, and Leeds. Small-pox caused 16 more deaths in London and its outer ring of suburban districts, and one in Leeds; no fatal case of this disease was recorded in any of the other large towns.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At a meeting of this Faculty, held on the 3rd inst., the following office-bearers were elected for the ensuing year, viz.:—Dr. Robt. Scott Orr, president; Dr. Robert Perry, visitor; Dr. James D. Maclaren, treasurer; Dr. James Finlayson, honorary librarian; Dr. Hugh Thomson, vaccinator. Councillors: The President, *ex officio*; the Treasurer, *ex officio*; Dr. James Morton, Dr. Andrew Fergus, Dr. Henry Muirhead, Dr. William Radie, Dr. Peter Stewart. At the same meeting Dr. Hugh Miller was appointed an examiner in midwifery, vice Dr. Tannahill. At one time the wholesome rule existed in this Faculty that no teacher should hold the position of examiner; for some time past the very opposite has obtained, as now, with few exceptions, all the examiners are teachers. Dr. Miller's election is a return to the former commendable state of affairs, and is thus to be regarded with satisfaction. It is obvious that in any modification of the present licensing system, under a new medical reform bill, the position of all licensing bodies would be less assailable to the extent that examiners are unbiassed by personal influences. We hope to see a return to the old *regime* at the Faculty of Physicians and Surgeons.

FEVER EPIDEMIC AT BRIXBURN.—Scarlet fever has been very prevalent for some time back in this village, especially

amongst children, and a good number of the cases have proved fatal, as many as fourteen deaths occurring in one week. There are said to be about ninety cases at present in the district. The causes assigned are bad ventilation and overcrowding.

DUNOON CONVALESCENT HOMES.—The twelfth annual meeting of the qualified donors and subscribers of the West of Scotland Convalescent Seaside Homes, Dunoon, was held on the 3rd inst. in the Religious Institution Rooms, Buchanan Street, Glasgow. Sir Peter Coutts in the chair, Mr. Maclean, the honorary Secretary, read the annual report, which stated that the past year had been one of unprecedented prosperity, much good work had been done, and the retrospect of the year gave great cause for thankfulness. At the date of last report 120 convalescents remained in the Homes, and since then 2,307 had been admitted, comprising 1,194 men, 1,001 women, 85 boys, and 87 girls. Eighty-one applicants were rejected as unsuitable, and 41 were delayed for a short time until becoming fairly convalescent. Of the total number admitted, 2,054 were perfectly restored, 109 were much improved, 45 were but partially benefited, 146 did not improve, 9 died, and 124 were now in the homes. The report concluded by stating that in another month the directors expected to receive payment of £5,000 from the trustees of the late Jessie Gordon.

ANDERSON'S COLLEGE SCIENCE LECTURES.—The opening lecture of the course on "Anatomy and Physiology" was delivered on the 5th inst. by Dr. A. M. Buchanan. Dr. Russell occupied the chair. Dr. Buchanan, at the outset, referred to the advantages which are to be derived from the acquisition of knowledge, and dwelt upon the organic and inorganic kingdoms of nature. Thereafter he explained the functions performed by animal organisms, and concluded by enforcing the claims which physiology has to advance upon the attention of the public. The talented lecturer was attentively listened to by a large audience.

PROSPECTS OF THE ANATOMY CLASS, UNIVERSITY OF EDINBURGH.—The number of students enrolled for anatomy at the University is said to be already over four hundred, and it is expected that the number ultimately enrolled will exceed that of last year. The dearth of material will be sorely felt, and if the classes continue to increase the University authorities will have to seriously consider some plan in order to supply more subjects, or the Anatomical School will lose its prestige. Mr. Symington, at the Minto House, has also a class of over one hundred, and as many of his students are second and third year's men, the prospects of a large class improves daily.

DR. ANGUS MACDONALD.—We regret to state that, owing to continued ill-health, Dr. Macdonald will not be able to lecture on Midwifery at Minto House this session. For this session this rising school will lose one of its most valued teachers. We hope that with rest and care Dr. Macdonald will soon be able to return to his professional duties.

MUNIFICENT BEQUEST TO THE EDINBURGH ROYAL INFIRMARY.—The late Mr. John Orphat, of Leuchars, Fifeshire, has left a bequest of £3,000 to the Infirmary, in remembrance of the great benefit his father derived in that institution when the science of lithotomy was practically but little understood.

THE COMBE LECTURES.—On Tuesday evening, Professor Stirling, M.D., Sc.D., of Aberdeen University, delivered the first of a course of these lectures in the Assembly Hall, Montrose. There was a large attendance, and the Professor was listened to with marked attention, and frequently applauded during the delivery of his address.

INFANDUM DOLOREM RENOVARE.—We are concerned, in

the interests of impressionable females, and weak-minded young men, to notice the arrival in England of Messrs. Moody and Sankey, of explosive revival fame. Former experience of the pernicious influences of the hystero-religious mania with which these clever men were identified, leads us to hope that most people will guard against an undue preponderance of the emotional passion.

THE EDINBURGH UNIVERSITY PRIZES.—The following prizes in the medical department of this University have been awarded:—The Ettles Prize for 1881 to Barclay Josiah Baron, M.B., C.M. The Beaney Prize to David Hepturn, M.B., C.M. The Goodsir Prize to Matthew Day, M.D. The Wightman Prize to Francis William Grant. The Buchanan Scholarship has been awarded to James Hewitson, M.B., C.M.

HEALTH OF EDINBURGH.—The deaths in Edinburgh for the week ending with Saturday the 1st inst., amounted to 71, equivalent to an annual mortality of 17 per 1,000. More than a third of the total was due to chest diseases. No fatal case of fever was reported, and the southern suburbs continue free from zymotic mortality.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday the 1st inst., were at the rate of 18 per 1,000 per annum, against 19 in the previous week, and 19, 17, and 22 in the corresponding periods of 1880, 1879, and 1878.

LEITH—A QUARTER'S HEALTH STATISTICS.—From a return just prepared it appears that the number of deaths during the past three months, in Leith, has been 254, which is equal to an annual death-rate of 16½ per 1,000. Nineteen deaths resulted from zymotic disease, six being from typhus fever, and four from scarlatina. Of the total number of deaths, 106 were of children under five years of age.

THE MATRICULATION OF THE ROYAL IRISH UNIVERSITY.

The first matriculation examination of the University will take place on December 6th, and application to be examined must be lodged on or before the 15th inst. The subjects of examination are as follows:—

1. Latin—Virgil, *Æneid*, book 1; Cæsar, *De Bello Gallico*, books 4 and 5. Latin grammar, with easy sentences of English to be translated into Latin.

2. Any one of the following:—*a.* Greek (Xenophon, books 3 and 4; Homer, *Iliad*, books 1 and 3; grammar; history). *b.* French (Telemaque, books 1 and 3; Racine's *Esther*). *c.* German (Schiller, *Wilhelm Tell*, act 1; Lessing's *Fabeln*; exercises on accident and syntax). *d.* Italian. *e.* Spanish. *f.* Celtic.

3. English (grammar; Goldsmith's *Traveller*; Macaulay's *Warren Hastings*; geography; composition).

4. Mathematics—*a.* Arithmetic (first four rules, fractions, proportion, square root); *b.* All rules up to simple equations; *c.* Geometry (Euclid, books 1 and 2).

5. Physics; Elements of Mechanics, Hydrostatics, and Pneumatics.

Students who have matriculated or taken a full arts year in the Queen's University will be exempted respectively from the matriculation and first examination in arts of the Royal Irish University.

Novelties.

NEW REMEDIES.

PARODI has discovered in the *Xanthoxylum Noronae-ellea*, a rutaceous plant which grows in the Argentine Republic, an alkaloid to which he has given the name of Xanthoxyline. The plant contains, besides a hydrate of

carbon, Xanthoxylon "C₁₀H₁₉" a crystallised principle and an aromatic volatile oil. The plant has the same properties as jaborandi which is also rutaceous.

Berganine is a crystallisable principle found in various species of saxifrage (Siberica, Cordifolia, Crassifolia), it behaves as an alkaloid, crystallises in alcohol in tetrahedra, in water in prisms. As a therapeutic agent berganine may be placed between quinine and salycine.

"SYRUP OF THE SIX HYPOPHOSPHITES."

(SYRUPUS HYPOPHOSPHITES SEX.)

Report on the New Preparation introduced by Messrs. Anderson and Adams, of Dublin.

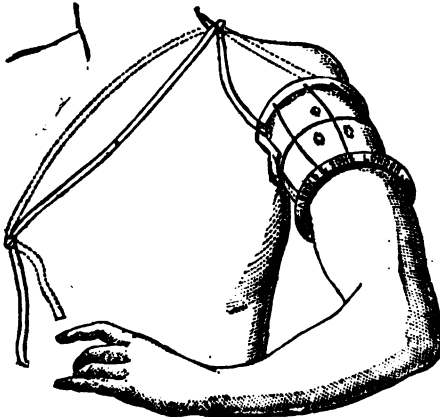

Messrs. Anderson and Adams, of Dublin, in bringing forward their syrup have evidently been induced to do so from the success of a somewhat similar syrup (Fellows' Syrup of the Hypophosphites).

The syrup made by Messrs. Anderson and Adams recommends itself to the profession, however, from the fact of its having an exact and published formula. It contains calcium, potassium, iron, and manganese in the soluble form of the hypophosphites, and combined with the alkaloids quinia and strychnine. We have had the syrup carefully examined by our analyst, and find that it contains 4 grains of quinine, and as nearly as can be practically determined a little under 8-10ths of a grain of strychnine. It contains therefore in a fluid drachm:—

Hypophosphites of calcium ...	1 grain
Hypophosphites of potassium ...	1 "
Hypophosphite of iron ...	1 "
(Chiefly ferrous salt)	
Hypophosphite of manganese ...	½ "
Quinine ...	4 "
Strychnine ...	1-64th "

It is a nearly neutral syrup. Not unpleasant to take for those who like bitters, and is a permanent preparation.

A VACCINATION SHIELD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The vaccination shield, of which the above is an illustration, was devised by me some month's ago (when the small-pox epidemic in London was causing considerable uneasiness), to obviate the pain and inconvenience attendant on the rubbing or adhesion of the sleeve to the vaccinated part; this it satisfactorily accomplished, and, moreover, as from its construction, no pressure is made either above or below the part operated on, no hindrance to the free circulation of the blood occurs, an advantage which, I think, will recommend it in cases of vaccination or adult re-vaccination. It is made in various sizes by Messrs. Arnold and Sons, West Smithfield.

I am, yours, &c.,

JOHN C. HOGAN, M.A., M.D.

16 Sisters Avenue, Clapham, S.W.

University of Edinburgh.—The following is the list of candidates who received the Degrees of Doctor of Medicine, Bachelor of Medicine, and Master in Surgery, at the recent Convocation:—

DOCTOR OF MEDICINE.

MASTER IN SURGERY (ONLY).
Smith, R. W., M.B.

THE ROYAL COMMISSION ON THE MEDICAL ACTS.

We understand that the Royal Commission on the Medical Acts will recommence its sittings on Friday next. The first witnesses to be examined are Dr. Barton, for the Royal College of Surgeons, Ireland; Dr. Finney, for the College of Physicians; and Dr. Moore, for the Irish Medical Association.

NOTICES TO CORRESPONDENTS.

DR. GUSTAV BRCK (Bern).—The "Funis Replacer" was described by Dr. Leeper in this Journal June 15th, present year.

DR. J. CHRISTIE.—Paper received shall have early attention.

MR. PARKIN.—If the case is as stated the offence is more against good taste than the law. We fear you would stand little chance of redress at the hands of lawyers.

AN OVERWORKED DISPENSARY DOCTOR.—Is the medical officer of a dispensary obliged to attend on red tickets improperly filled? For instance, if a ticket is filled up by a guardian's wife or daughter, even though it bears the *bond fide* signature of the guardian authorised to issue it, does the medical officer incur any risk in refusing to attend on it? Can he legally refuse to attend on such a ticket?

[According to the "direction for filling up relief-tickets" issued by the L.G.B. (page 261, "Irish Medical Directory"), "the ticket and counterpart are both to be filled up by the person authorised to issue the ticket." You are, therefore, fully entitled to disregard the ticket and refuse to attend on it if the body of it is filled in by any one but the signer of it. The L.G.B., however, tries to compel the medical officer to attend under such circumstances, and any one who refuses to do so must be prepared to defend his position. We think your best course will be to attend under protest, and then send the ticket, with a remonstrance, to the L.G.B.—ED.]

MR. HY. WOODS.—We cannot do more than refer you to the article in our issue for Sept. 28th, head "Books and reading for Students."

F.R.C.S.—1. The matter will be referred to in an early number. 2. Uncertain at present.

A THIRD YEARS' MAN.—Decidedly amusing, but hardly suitable for our columns. Send it to our more juvenile contemporary the *Student's Journal*.

A HOMOEOPATHIC QUERY.—A correspondent asks, "How is it your straight-laced contemporary, the *Medical Times and Gazette*, now inserts advertisements of the homoeopathic school, when but two or three years ago it not only refused to contaminate its columns by their admission, but even abused the *Lancet* and *Medical Press* for countenancing them. Is this another example of allopathic consistency?"

[With the latter query we need not concern ourselves; our constant endeavour is to be consistent in the discharge of our public duties, and to leave the conduct of other journals to their responsible conductors. Until the receipt of our correspondent's letter, we were unaware that homoeopathic advertisements were appearing in the *Medical Times*, but having satisfied ourselves with its correctness, we must leave the Editor of that journal to explain the reason why. Certain is it that a short time since the *Medical Times* did refuse these same advertisements, and made an appeal to the other journals to follow their example. The *Lancet* and the *Practitioner* followed suit, but we declined to accede to the request on the same principle that, although strongly deprecating homoeopathy, we never refuse insertion to the letter of a homoeopathic practitioner on a debated subject. Perhaps our contemporary, the *Medical Times*, has been stranded on the toleration theory propounded by Dr. Bristowe and Mr. Jonathan Hutchinson.—ED.]

MR. HAMILTON.—Police fees are paid at stated times at the Government Office, and you have no means of recovering anything beyond the miserable apology for remuneration recognised by law. You are certainly entitled to the guinea for the post-mortem, and you should firmly refuse to forego the amount on any consideration.

A CHANCE FOR NON-SMOKERS.—Inebriate asylums and private houses in which the occupants are ready to receive confirmed toppers with the view of turning them from the error of their ways, are well known and freely advertised; but modern civilisation is about to make another move in the direction of reclaiming excessive smokers. In our advertising columns will be found an announcement by The Friends of a middle-aged gentleman who is seriously injuring his health by smoking who is anxious to place him under the care of a medical man who will undertake to prevent the possibility of his patient smoking. To place the impossible across the path of the intemperate in drink is usually found to be a task of heroic proportions, but to prevent the semi-narcotised *devoles* from secreting tobacco up his sleeve or in his lining, would be to deprive him of his coat, and this extreme measure, we presume his friends are not prepared to sanction just at this season.

STUDENT SAYS.—Last October, I passed the Matriculation Examination of Queen's College, Galway, but did not get a certificate. As I cannot attend lectures until next November twelvemonths, shall I then

be matriculated in the Royal University, or if not, what must I do about it?

[The Matriculation, if duly certified, will be sufficient to enable our correspondent to go on in the Royal Irish University.—ED.]

THE SOCIETIES.

THE HARVEIAN SOCIETY OF LONDON.—The opening meeting of the session will be held on Thursday, Oct. 20th, at 8.30 p.m., when a paper will be read by Dr. J. Milner Fothergill on "Emulsification of Fat."

HUNTERIAN SOCIETY.—This (Wednesday) evening, at 7.30, Council Meeting.—8, First General Meeting: Introductory Remarks by the President.—Mr. T. Hutchinson, "On Second Attacks of Syphilis."

ROYAL MICROSCOPICAL SOCIETY.—This evening, at 8, Mr. B. Wills Richardson, "On Multiple Staining of Animal and Vegetable Tissues."

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Thursday, Oct. 18th, at 8.30 p.m., Mr. J. E. Adams, "On Unifocal Diplopia."—Dr. W. M. Ord, "On Cases of Unifocal Diplopia."—Mr. J. E. Adams, "On Cases of Suppurating Ophthalmitis from Septic Embolism."—Dr. Bralley, "On a Case of Tuberculosis of the Eye."—Dr. Walter Edmunds, "Microscopical Specimens:—(1) Tube of Choroid. (2) Perineuritis Optica twenty-four hours after Fracture of Skull.—Living Specimens at 8 o'clock."

CLINICAL SOCIETY OF LONDON.—Friday, Oct. 14th, at 8.30 p.m., Dr. Wiltshire, "On a Case of Ruptured Ovarian Cyst."—Mr. Christopher Heath, "On a Case in which a large Odonotome was successfully removed."—Mr. C. B. Keetley, "On a Case of Charcot's Joint Disease" (Living Specimen).—Mr. C. T. Dent, "On a Case of Strangulated Hernia" (Littre's).

Vacancies.

Bandon Union, Bandon Dispensary.—Medical Officer. Salary, £100, and £20 as Medical Officer of Health. Election, Oct. 19.

Birmingham General Dispensary.—Resident Surgeon. Salary, £150, with an additional allowance of £20 per annum. Applications to the Secretary before Nov. 10.

Jersey General Dispensary.—Visiting and Dispensing Medical Officer. Salary, £130, with furnished rooms. Address the Hon. Sec., the Parade, Jersey.

National Dental Hospital College.—Dental Surgeon and Lecturer on Dental Surgery. Candidates must possess the L.D.S. Eng. Applications to the Secretary, 149 Great Portland Street, London, W., by Oct. 25.

Oughterard Union, Lettermore Dispensary.—Medical Officer. Salary, £100, and £10 as Medical Officer of Health. Election, Oct. 18.

Rathfrum Union, Annamore Dispensary.—Medical Officer. Salary, £120. Election, Oct. 22.

St. Andrews Hospital for Insane, Northampton.—Assistant Medical Officer. Salary, £200, with board, &c. Applications to the Medical Superintendent.

Appointments.

DULTRELL, M. H., M.R.C.S., L.R.C.P.Lond., Surgeon to the Provident Dispensary of the Royal Albert Hospital, Devonport.

BUSBY, R. A., M.R.C.S., Resident Medical Officer to the Bath General or Mineral Water Hospital.

CADDY, H., M.R.C.S.E., Medical Officer of Health of the Eastern Division of the Truro Rural Sanitary District.

KADON, W. F. B., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for the Second District of the Chipping Sodbury Union.

GRAHAM, C. R., M.R.C.S.E., L.R.C.P.Ed., Senior Resident Medical Officer to the Hospital for Sick Children, Pendlebury, Manchester.

TRIMHARNE, J. L., M.R.C.S., Medical Officer for the Spottedlands District of the Cardiff Union.

WICKHAM, W., M.R.C.S., Medical Superintendent to the Poplar Board of Works Small-pox Hospital, Plaistow.

ARMY MEDICAL DEPARTMENT.—The following were gazetted on Sept. 30th:—Brigade Surgeon H. J. Rose is granted retired pay, with the honorary rank of Deputy Surgeon General; Surgeon Major R. C. Parkinson has been placed on temporary half-pay.

Births.

LYON.—October 7, at Houghton-le-Spring, Durham, the wife of Walter Lyon, M.D., of a son.

THOMPSON.—October 2, at 0 Cranley Place, South Kensington, the wife of Reginald E. Thompson, M.D., of a son.

WIDDUP.—October 4, at 77 Wellington Road, the wife of J. C. Ponsoby Widdup, Esq., M.D., L.R.C.S.I., of a daughter.

Marriages.

WADE—AMBLER.—October 5, at St. Mary Magdalene, St. Leonards-on-Sea, Arthur Law Wade, M.D., to Louisa Jane, second daughter of the late Thomas Ambler, Esq., of Hornsey Rise, London.

Deaths.

BARTLETT.—October 4, at Dawlish, Devon, Edward B. Bartlett, L.D.S., B.C.S.K. late of 38 Connaught Square, London, aged 67.

BRITAIN.—On October 2, at Boilard's Court, Chester, after thirty-six hours' illness, Thomas Britain, F.R.C.S., aged 71.

CONSIDINE.—September 29, Dr. Michael Considerine, of Galway, aged 62.

HARDING.—September 21, at 84 Gresham Road, Brixton, William Henry Harding, L.K.Q.C.P. and M.R.C.S. aged 40.

CURTIS.—On October 7th, at Alton, Hants, William Curtis, M.R.C.S., aged 78.

HITCH.—On September 29, at Eastbourne, Samuel Hitch, M.R.C.P., Lond., in his 81st year.

PLAYFAIR.—On October 4, at Longridge Road, S.W., G. Ranken Playfair, M.D., late Inspector-General of Hospitals, Indian Army.

utmost degree of attention, frequency, and speciality of treatment that his patient's patience will endure."

It is well to classify "specialities" and their commonly attended "specialisms," and this which is now proposed is a somewhat "natural order." First of all, the distinction between those who deal with men, women, and children, then, secondly, those who treat either of those groups of patients as sane, or insane; thirdly, those who divide certain parts of the human being upon a somewhat regional, anatomic-physiological basis, and take as their fields for cultivation, nervous system, respiratory system, digestive system, and the like; fourthly, those who make particular diseased conditions, such as gout, fever, their line of study; fifthly, those who take special lines of work, such as medico-legal practice, in courts of law.

1. *Men, Women, and Children.*—To what does specialism often lead? There are many surgeons in large cities who never, except by caprice, accident, mistake, or good nature, find a lady in their consulting-rooms. They have to treat what they find in the so-called "sterner sex," and their practice becomes somewhat closely confined to a particular class of maladies that most frequently arise from irregular modes of life, of which many of them are ashamed. There are those who have chosen this speciality, and done what they have to do, with good to their patients, credit to their profession, and honour to themselves. But this cannot be said of all. Are there not some who prey upon the sense of shame, and extort money for needless operations, and worthless drugs, holding in terror over their victims the knowledge of facts that have been confided to them, and using that knowledge, which is power, to benefit, not their patients, but themselves? Are there not undergraduates and others who dare not "call in the family doctor?" and are there not "potent, grave, and reverend seniors," who are just as anxious as their sons may be that nothing of their malady should be known at home?

The consulting-room—as sacred as the confessional—is degraded by the lowest depths of degradation when it is used, or abused, as the engine of terror and extortion. But yet debts are incurred, and bills are drawn, and Jews are sought for, aye, and Christians too, in order to meet the so-called "obligations" of these sufferers. The surgeon has the power in his hand, and he knows it, and wields it often with a cruelty that no words of mine can utter, or efficiently condemn.

The surgeon who resorts to no such baseness as this might, I think, in another way, be helped if, occasionally, he had some other things to do, and were, every now and then, consulted by some few of what is called the "softer sex," of pure life, and exalted character; some one of virgin soul, or matron dignity, who might break in upon the routine of daily practice, and teach, by their bearing and anxiety, a higher lesson than that which is learned mainly in the chatter of the clubs. The surgeon becomes rough and ready, and there are hundreds to speak well of his skill; and often his roughness has risen to such point that men will say, "I cannot see so-and-so, he is so outrageously rude and overbearing."

We know that there are a large number of physicians, and a very small number of surgeons, who devote their lives to the treatment of women, and who do their work well; never shunting a duty, never overstating a case, never condescending to anything in their practice that they would object to inspection by the *élite* of their professional brethren. They have studied, have learned, and have taught; and their lives are as valuable as they could wish them to be.

But we know that there are others of whom this cannot be said. Physicians have coined names for trifling maladies—if they have not invented them—and have set "fashions" of disease. They have treated, or maltreated, their patients by endless examinations, speculations, applications, and the like; and this some-

times for months, sometimes for years; and then, when by some so-called accident the patient has been removed from their care, she has become quite well, and then there has been no more need for caustic, speculum, or pessary.

The profession is not altogether to blame for this. Such is the want of education on physiological matters, that women do think and feel a great deal more about any "irregularities" of a certain kind than there is reason for them to think or feel. They attach an amount of importance to dysmenorrhœa entirely out of proportion to that which they render to dyspepsia; and tight lacing and ball-dressing, and all that they involve, are disregarded, so long as these special functions are not disturbed. But when anything goes wrong in such way that the "lunar periods" are put out, then the specialist is consulted; and happy is it for them if the doctor himself does not suffer from specialism. If he does not, he treats the patient as she ought to be treated. If he does, too often he "makes a case" of it; and then follows the whole ritual of what I need not describe.

Some years ago *ulceratio uteri* was the fashion, and applications of various sorts were made two and three times a week in order to cure a malady which some eminent men, in special practice too, said did not exist. Lately I have rarely heard of this complaint; the disease has died a natural death, or has met with a violent end. But now, according to some authorities, there is scarcely any woman living whose uterus is where it ought to be. It is anteverted, or retroverted, or verted this way or that way, so that all kinds of contrivances have to be adjusted or readjusted in order to cure backache, vesical irritation, albuminuria, hysteria, and I know not what besides. Now, when all this is done by some one who knows with what he is dealing, and honestly deals with it, as many do, much good may be accomplished. But when imitators of the good workers take such cases in their hands, nothing but harm can follow. There is meddling and muddling of the most disreputable sort, and the patients after a time grow sick of it and give it all up, and get well; or they go on from bad to worse, and become chronic invalids, and a great trouble to themselves, their relations, and their friends.

There are the consulting rooms of some doctors that are as they ought to be; there are others soothed by "a dim (can I say?) religious light," into which the patients are ushered, and in the dim silence of which all this kind of "treatment" goes on. And not only so, but in their own homes, patients are sometimes treated by—or shall I say to?—a vaginal injection of warm water, which the physician himself must administer.

This kind of thing is "specialism," and in one of its worst forms. It is the taking advantage of a natural solicitude on the part of women, and of their undue anxiety; and instead of correcting it by steady purpose and common honesty—of pandering to the weakness of human nature, petting their patients into a feeble condition of dependence, and rendering them unfit for life, in all its personal and domestic relations.

If some surgeons may be at fault in seeing life only as they read it in the clubs, surely some specialistic physicians are also to blame in looking at life only as they see it through a speculum; and it would be of advantage to them if they could occasionally have men for their patients, and so lose a little of that tendency to soft words and compliments, in the use of which they are such conspicuous adepts.

There is not much that need be said about specialism with regard to children. They are virtually unsexed, and so do not fall into the hands of either of the classes of practitioners that I have mentioned. But it is quite possible for the man who deals solely, or even mainly, with children's diseases to take an exaggerated view of their differences from those with which adults may be afflicted, and so construct a pathology and a therapeu-

ties which may be of disadvantage to the profession, and of no real use to the child. Specialism can scarcely be said to exist here, unless it be the physician sometimes taking upon himself the functions of the nurse, and seeing almost all things from a nursery point of view.

2. *Sane and Insane*.—The speciality of the physician who directs his attention mainly, or, it may be, even exclusively, to the charge of the insane, is a most direct advantage to the profession and the public; and this is demonstrated by the fact of its general recognition. This is true, however, only when the physician is at times competent to treat the other bodily ailments that may range themselves around the brain-disease with which he has primarily to deal.

The fault of "specialism," however, in this department is, that the so-called "mad-doctor" fails, sometimes, to see anything from a sane point of view. The *mens sana* is a myth to him, and he cannot bring himself to believe in its existence. He may think that it exists in *corpore sano* of his own possession, and in other corpora of his friends; but, beyond that narrow range, the sane mind is not to be found in those who are suffering from anything which may perturb the current of their thoughts. He may be right in regarding all people as somewhat mad, but he may be wrong in thinking that all men are so far mad as to require restraint.

There can be no doubt as to the fact that men and women have been, in the past, and sometimes—but much more rarely—in the present, dealt with as insane, when they were simply incompetent, vacillating, eccentric, extravagant, or perverse. But, the mode in which "specialism" becomes mischievous in these physicians is this: that they have but one idea; and that is, that the patient must be secluded, or sent to an asylum to be treated; and the upshot of such advice often is that the patient is not "treated" in any other sense than that he or she is delivered over to the care of attendants, who are not always of the best-informed, the wisest, or the kindest sort.

The physician who is affected with "specialism," in regard to the insane, seems to take his stand upon the threshold of an asylum—half in, half out; and, holding that to be the standpoint for the observation of human life and human history, can base his creed with regard to both of them upon the facts that lie beyond him, and not look, face-outward, into the world beyond.

3. *Regional Physiology*.—There are "specialisms" in regard of nervous system, of lung and heart systems, of digestive systems, and the like; and, with regard to them, I have but this to say, that the faults lie in the incompetency which many who have devoted themselves to one line of study often exhibit in their analysis and diagnosis of cases, into the complicated conditions of which their speciality of study has prevented them from entering.

Thus, I have known learned and distinguished "head-doctors" speak of grievous palpitation of the heart as a merely nervous phenomenon, when the patient had dilated heart, with obvious valvular disease; of dyspnoea of very trying sort as a "nervous condition," when there were, in addition to dyspnoea, cough, exacerbation, and the physical signs of "emphysema," chronic bronchitis, dilated bronchi, and enfeebled heart; of short breathing described as "hysterical," when one half of the chest was filled with fluid.

On the other hand, "heart and lung doctors" have failed to trace that anything was the matter, because the stethoscope could tell them nothing, when it was obvious that disease of the spinal marrow in some cases, and disease of the kidneys in others, was the cause of altered breathing.

Again, it has often been my lot to see "digestion-doctors" worrying their patients with blue pill and elaterium, and bring them to the verge of extinction from

not having been able to discern that a diseased heart was the *font et origo* of their sufferings.

4. *Special Diseases*.—With regard to these, "specialism" is sometimes more interesting and amusing than directly mischievous. There are consumption-doctors, cancer-doctors, gout-doctors, and the like. If the former send their patients to the Riviera, or the uttermost parts of the earth, when it was unnecessary for them to make such pilgrimages, they, at least, have had the benefit of seeing new scenes, and sometimes of acquiring the knowledge of a foreign tongue. If cancer-doctors have given, with grave looks and graver forebodings, a diagnosis and prognosis that may have been most distressing, yet sometimes tears have been turned into joy, when the tumour has disappeared, and the cancer of the liver has turned out to be a "gall-stone." If "gout-doctors" have given their patients very wise instruction as to life and diet, they have been often rewarded by the extermination of "the fear of the evil" that the patient suffered from, and have found favour in their sight.

5. *Lines of Practice*.—This one illustration that I will give now is that of the "specialism" which affects many members of our profession when they are in the frequent habit of giving evidence in courts of law, and I will take for example that which happens in the case of railway accidents. It is pretty well known who, among the physicians and surgeons of the day, will be called upon for the plaintiffs, the injured, and who for the defendants, the company. So familiar in legal circles has this knowledge become that the phrase, "So and so is a very rising witness" has been used, and not unfrequently. What does this mean but that members of our profession, whose only object should be truth and justice, "take sides?" Many years ago much of this came under my notice, and I alluded to it in some lectures which I had the honour to deliver before the College of Surgeons; but for many years I have declined to take any part in such proceedings, owing to the manner in which evidence was given by what I must call "party witnesses."

It seems to me quite unpardonable that six or eight members of our professions should meet together, and go through the farce of a so-called "Consultation" when neither one of the physicians or surgeons, on either side, would interchange a single word with one another. I have tried to break through this absurdity more than once, and sometimes have succeeded in my attempt. But more frequently I have failed, and have given it up; and this because I have heard said in courts of law such things as were so utterly unscientific, ignorant, or perverse, that it was simply impossible to deal with them. One instance will suffice; after rather understanding a case of hemiplegia, the result of accident, it was urged, "on the other side," by an eminent surgeon, that the man was shamming because, forsooth, he did not exhibit ptosis, strabismus, and dilated pupil, and that he had never seen a case of hemiplegia in which those three things did not coexist.

There are some members of our profession who have become specialists in this direction, who seem to think that everything that a man tells them of his subjective symptoms are matters of fact and of great importance; and, on the other hand, there are those who regard every plaintiff as either a knave or a fool, the most probably a combination of the two, but who never believe that any man is injured in a railway accident unless he has broken his neck, or has a compound fracture of his thigh.

It is time that this specialism should come to an end; and we, of our profession, can bring it to an end, if we will but insist upon it that the meetings together of the doctors is a consultation, and not a farce.

There are many other points upon which I should have liked to speak to you, of the specialisms that have so limited an area that it is quite possible for any man, who is restricted to any one of them, to make an income,

unless he does so by inducing his patients to pay him for needless visits; such, for example, as to touch his throat with something every day; to turn the screw on his "instrument for the back" two or three times a week; or to do something to the Eustachian tube with equal frequency. But what I have said is enough to guard you, I hope, from falling into these mistakes, these "worse than crimes, these blunders."

In conclusion, let me revert to "differentiation" the springing into being of varied structures, with their varied uses, and of their development into the being of a perfect whole—a living thing, with complex powers—all its parts subservient to the ends for which they were intended, and for which they are so ordained as to conduce to the "survival of the fittest"; but let me carry the illustration yet further, and say that all these different members are members one to another, and that when any member suffers all the other members suffer with it; and that when any physician or surgeon does that which is ignoble, he not only does injury to himself, but to the whole of the noble profession to which he belongs.

GERM INOCULATION. (a)

By CHARLES CAMERON, M.D., LL.D., M.P.

(Concluded from page 316.)

BUT to return to the bacterium of fowl cholera. The vehicle of cultivation employed by Toussaint not proving satisfactory, M. Pasteur's first care was to find a more congenial medium, and this he soon discovered in chicken soup. If the point of a needle be dipped in the blood of a fowl suffering from chicken cholera, and then placed in a vessel containing pure chicken soup, from which care has been taken to exclude all contamination by air-borne germs, and a suitable temperature be maintained, the bacterium or microbe—as M. Pasteur terms it and cognate organisms—multiplies itself exceedingly, rendering the liquid turbid by its presence. If, after this process has gone on for some days, a drop of the contents of this vessel be transferred to another portion of similar chicken soup, it, too, speedily becomes permeated with the organism. The process may be repeated a hundred times, and the result inoculated upon fowls, or given them in their food, will produce the same fatal effects. But if, instead of carrying on these fresh cultivations at intervals of a few days, you allow the infected chicken soup to lie over for a few weeks or months, Pasteur discovered that an extraordinary change occurs. The malignant powers of the bacterium diminish; it becomes, so to speak, tamed, or, as he terms it, "attenuated." A given quantity of infected chicken broth, even at the hundredth rapid cultivation, inoculated upon twenty chickens, would, let us say, prove fatal to eighteen of them. If the same infusion were allowed to remain exposed to the oxygen of the air for a month, it would be so far attenuated that it would only prove fatal, say, to ten. Exposure for another month would render it still less virulent, so that it would only prove fatal to two or three; while after exposure for six or eight months it would not prove fatal in a single instance. But does it still retain any active power? and if so, what relation does it manifest to the original disease? In its most attenuated form the bacterium gives rise only to trifling local symptoms, not at first recognisable as bearing any affinity to the deadly fowl cholera, and consisting of a small local slough. But the extraordinary and valuable fact discovered by M. Pasteur is, that the tamed and attenuated organism works upon the system a change protective against subsequent attacks of fowl cholera, exactly similar to that which had been remarked to be enjoyed by fowl that had recovered from the virulent form of the disease.

Here, then, is a result exactly analogous to that experienced in the protection exercised by vaccination with cow-pox against subsequent attacks of small-pox, only in the one case the protective virus has been elaborated in the laboratory of nature, in the other in that of art.

Time will not permit me to do more than allude to a few of the many curious and interesting features elicited in M. Pasteur's research as to the life-history of this parasite. It is rapidly fatal to fowls or rabbits, but turkeys and guinea-pigs resist its effects, and in these it gives rise simply to localised abscesses. If, in the course of its attenuation, a series of rapid cultivations be made from a stock of any particular strength, the produce retains the same strength. If the stock killed ten fowls in every hundred, its progeny will continue to kill the same proportion. If it has been attenuated below the fatal point, the stock derived from it continues to present the same benignity of character. One most important fact elicited is this, that, altogether contrary to what one would expect, the most virulent organism is to be found, not in the ordinary rapidly fatal cases where the fowl dies in the course of a few days, but in a much rarer form of the disease, where the bird lingers for weeks or months. Then the microbe acquires such virulence that the fraction of a drop of blood charged with it inoculated on a score of hens will kill every one of them within four-and-twenty hours. And yet even this doubly poisonous species of the organism can be reduced to a harmless vaccine by artificial cultivation, and between its most and least deadly forms the microscope does not enable us to detect the smallest difference.

What is the theory of the protection which this new vaccination affords? I will not enter into the details of the theories which have been advanced; suffice it to say that the world has long been familiar with the fact that one occurrence of a certain disease—such as small-pox, measles, scarlatina, typhus, &c.—in an individual, effects a change in the constitution which, except in very rare instances, is protective against any recurrence of the same complaint. Recent discoveries prove that in certain instances a similar change is effected by diseases not identical with those against which they protect. Thus, Pasteur has found that inoculation with fowl cholera renders at least one class of animals refractory against subsequent inoculation with splenic fever, although the organisms which give rise to the two diseases are entirely distinct. But in the course of his researches into the mechanism of the protection thus conferred, M. Pasteur discovered a very curious and interesting fact. One of the most prominent symptoms of ordinary fowl cholera is an irresistible drowsiness which overcomes the fowl attacked. It lies down, falls asleep, and is with difficulty awakened, only to sleep again until finally death overtakes it. Well, M. Pasteur, in the course of his researches, filtered some chicken broth in which the disease-organism had been cultivated, so as to free it from all traces of it, and injected the liquid into the circulation of healthy fowls. After a short time they exhibited the same symptoms of overpowering sleepiness, and that whether they had been rendered proof against the disease by previous inoculation or not; but instead of dying, after four or five hours the symptoms passed off, and they were restored to perfect health. This proves that, in the course of its development, the organism of fowl cholera by a fermentative action gives rise to a narcotic poison which occasions this symptom, a symptom which masks the essential phenomena of the disease, but which can be altogether separated from it, and is only indirectly incidental to it. In the typhus fever of man a similar symptom is constantly noted, and the question naturally presents itself, Is it produced in a similar way? Here is a curious fact bearing on the point. In Senegal the natives are subject to a terrible disease known among them as *malavan*. The disease takes eighteen months or two years to run its course. It is attended with acute pain, stiffness of the limbs, glandular abscesses, and notably with

(a) Abstract of an Address delivered before the Social Science Congress at Dublin, Oct. 6, 1881.

constant drowsiness, the sleep being heavy and accompanied with terrible dreams. The patient preserves his appetite to the last, but often loses his reason, and invariably dies. A French missionary in Senegal addressed a communication on the subject to M. Déclat, a French physician and an ardent disciple of Pasteur's, who suspecting in the disease a parasitic origin, recommended the missionary to try a treatment having for its object the destruction of the organism—its probable cause—by the injection into the circulation of phenic acid. The experiment was made in several cases, notably in one where the patient was in so advanced a stage of the disease that the missionary was only induced to try the treatment by reflecting that if it did no good it could do no possible harm; and in every instance the result was success. The organism was killed and the patient recovered.

Turning now to the *Bacillus anthracis*, the organism which gives rise to splenic fever in cattle, M. Pasteur found that it, too, could be cultivated in chicken broth. In its case, however, a preliminary difficulty was experienced. The class of organisms to which the *Bacillus* belongs multiply themselves in two ways—by subdivision of their cells into other cells, which rapidly attain the dimensions of the standard cells; and secondly, by a process analogous to that of flowering in the higher classes of plants, resulting in the production of spores or seeds. In the organism which gives rise to the potato disease, for example, and in many other cases, the cells throughout the summer spread and multiply themselves within the tissues of the invaded plant by subdivision; but on the approach of winter they make their way to its surface, and there go through a process analogous to flowering, which results in the production of spores or germs extremely tenacious of life, and which, like the seed of the higher plants or the eggs of insects, are unaffected by frost, and ready at any moment under favourable circumstances to spring into active life. So tenacious of life are these spores in the case of the *Bacillus* of splenic fever, that M. Pasteur has found them in full vitality in pits in which oxen and sheep that had died of the disease had been buried for ten years. He has proved, too, that when thus buried, swallowed by earthworms in the soil from which these derive their nourishment, they are brought by them to the surface, and may thus give rise to fresh outbreaks of the disease. He found that this was the case in an instance where a bullock had been buried in a pit over six feet deep. His proofs were absolutely conclusive. He placed sheep on the ground, and they took the disease. He separated the *Bacillus* germs from the earth by washing it, and multiplying them by cultivation, found that by inoculation they produced the disease. He found them especially in the casts brought to the surface by earthworms, and in the contents of their digestive organs; and he found, further, that in districts where the soil was of such a nature that earthworms were rare, the disease, when accidentally imported, was not found to spread.

Here is an anecdote which curiously illustrates how scientific discoveries may come about.

In 1865, Baron Seeback was Saxon Minister at Paris. Having suffered severely from splenic fever on his estate, he took great interest in the subject, and had evidently conversed with the French Minister of Agriculture respecting it. The result was that he was asked to detail his experiences in a memorandum. That memorandum the French Minister placed in M. Pasteur's hands, and it seems to have given him the clue to the manner in which the disease is spread. It has recently been published. In it the Baron narrates various circumstances which had induced him to think that his enormous losses from splenic fever were due to the propagation of the disease from the graves of dead animals; but what confirmed him in his suspicions was this: a sheep that had died of the disease had been buried in the corner of a field on which a crop of corn had subsequently been grown, and which the fol-

lowing year was sown with clover. The attention of the Baron had been accidentally directed to the place at the time, and one day in passing he remarked that the clover had grown with exceptional luxuriance over the spot. A few days later he noticed that some one had stolen the clover which grew at the corner of the field. The next day a woman on his property came to him weeping, to tell him that her goat had just died, and her cow was very ill. The disease was found to be splenic fever, and the woman confessed that it was she who had stolen the clover, and given it to the unfortunate goat and cow.

But to return to M. Pasteur, and his experiments in cultivating the *Bacillus* of this disease. He was not the man to allow himself to be foiled by the perversity with which this organism insisted, when artificially cultivated, on running to spores. He found that, by maintaining his chicken broth at a temperature of about 110° F., he could prevent spores from being developed, and induce the organism to multiply itself by subdivision like its congener in fowl cholera. He found that when this was accomplished, precisely the same results followed exposure to the atmosphere as had followed in the other case, but with much greater rapidity; that the organism could be tamed, that a virus could be produced of any desired degree of attenuation, and that when it was sufficiently attenuated, inoculated upon sheep or cattle, it gave rise only to trifling constitutional results, but at the same time wrought such a change in the system of the animal as protected it against subsequent attacks of splenic fever, just as effectually as was known to be the case when an animal recovered from the natural disease.

The annual losses to France from splenic fever being close on a million sterling, the commercial value of this discovery was too great to allow it long to remain without a public test. In May last, at Melun, before a number of scientific authorities, fifty sheep were taken, twenty-five inoculated with the attenuated or tamed organism, and ear-marked, and the others left untouched. A fortnight afterwards the whole number were inoculated with splenic fever. On the twenty-five previously inoculated with the attenuated *Bacillus*, no result followed. As to the others, within fifty hours the whole number were dead of splenic fever. A similar public test, undertaken in July, exhibited precisely similar consequences. Since then, many thousands of animals have been inoculated with the attenuated virus, and the commercial results of the experiment will soon speak for themselves.

The practical utility of M. Pasteur's discovery is greatly enhanced by the tendency, to which I have just referred, of the *Bacillus* of splenic fever to produce spores. The spores produced by the organism at any stage of attenuation give rise to a race presenting the same degree of attenuation, so that once a virus sufficiently attenuated has been obtained, it has only to be allowed to produce spores to secure a vaccine which will keep indefinitely, under any conditions of temperature, and is ready for use whenever required. But M. Pasteur has discovered that not only can this *Bacillus* be attenuated, but that by a converse process it can be restored to its original virulence and ferocity. This *Bacillus anthracis* appears to be an organism of very cosmopolitan taste, so far as mammalia are concerned; for though it is chiefly known to us as infesting cattle and sheep, it also, when accidentally inoculated on man, gives rise to that terrible disease known as malignant pustule. It lies hid in the condition of spores, in hair of horses, and the wool of sheep that have died of the disease, and finding its way, along with other dust, to the lungs of the people who handle them, occasions another terrible malady, known as Hairworker's or Woolsorter's Disease—and it particularly affects the class of Rodentia. In them this *Bacillus* appears to find a most congenial home, and in them it flourishes with a deadliness peculiarly characteristic. Now, M. Pasteur discovered that if the attenuated *Bacillus*—the organism tamed through long cultivation in oxygen—be cultivated through a succession of young guinea-pigs, it will speedily re-acquire all

its original virulence. That this is not an isolated fact in the history of such organisms, is shown by the circumstance that a similar recrudescence can be effected in the case of the virus of fowl cholera, by repeated cultivations of the attenuated organism on small birds, such as sparrows, to which it proves fatal long after it has ceased to be capable of destroying the life of fowls.

Time presses, and I shall only refer to one other curious discovery, made in the course of M. Pasteur's investigation. I relate it because it seems to cast some light on the success which has attended the treatment of certain fevers to which mankind is subject, by cold affusions. M. Pasteur discovered that if you introduce the bacillus of splenic fever into the circulation of the fowl, under ordinary circumstances it produces no result. The temperature of the fowl's body appears to prevent its multiplication in the system. Cool down that temperature, however, by placing the fowl in water, and repeat the operation, and the disease at once manifests itself. Let the temperature rise, the organism perishes, and the fowl revives. And here I shall for the present leave M. Pasteur, and briefly recapitulate the results obtained—most of them, be it remembered, within the last few months—by other labourers in the same field.

There is another disease of cattle equally fatal in its results with splenic fever, but distinct from it, and known amongst French veterinarians as *charbon symptomatique*, or, from the name of the author who first described it, *la maladie de Chabert*. Now M. Chauveau—to whose researches I have before referred—had proved that very different results followed on the introduction of certain morbid viruses into the animal system, according as they are carried right into the blood by injection into a vein, or simply introduced into the tissues, outside the circulation. More recently, in investigating the strange resistance displayed by Algerian sheep to the power of splenic fever, M. Chauveau found that it could be overcome by the introduction of large amounts of the specific organism into the system. By carefully limiting the number of bacilli introduced however, he found he could give rise to a trivial infection, which increased the natural resistance of the animal to subsequent experimental inoculation with the disease. Working on the lines thus disclosed, three young veterinary surgeons of Lyons, MM. Arloing, Cornevin, and Thomas, discovered that if the micro-organism, which gives rise to the *maladie de Chabert*, and which can also be artificially cultivated, be injected in carefully graduated doses into the torrent of the blood, so that the tissues shall not be contaminated, it gives rise to but very trifling constitutional disturbance, but at the same time produces a change in the system of the animal which effectually protects it against subsequent attacks of the disease. The matter was publicly tested at Lyons in June last. The virus of the *maladie de Chabert* was inoculated on one ram, four calves, and a ewe. The ram which had not been treated by the process died in two days. None of the other animals which had been subjected to it suffered any inconvenience. They had been vaccinated—to use the word in its extended sense—at periods ranging from fourteen months to a fortnight previously, all except one, a calf about a fortnight old that had never been vaccinated itself, but whose mother had been subjected to the operation some time before its birth. M. Arloing and his colleagues have now reduced their method to a system, which, they state, renders accidents impossible, and it too the French Government are now engaged in testing on a large commercial scale.

Let us now turn to another disease, which is probably the last in the world that you would suspect of being due to a parasitic organism—rabies or hydrophobia. M. Pasteur has been working at it for some time past, and he has made some extraordinary discoveries. Among other things, he has found that the saliva of a boy who died of that disease contained organisms which could be cultivated artificially, and that the result inoculated on rabbits, produced a disease which proved fatal with startling rapidity, but was quite distinct in its symptoms from any known form of hydrophobia. M. Pasteur considers this to be a new and distinct disease, but as yet no practical result of his investigations

has been published. Meanwhile, M. Galtier, another veterinary surgeon of Lyons, who for years past has made a special study of rabies, adopting a hint from the result of the investigation of his colleagues with respect to the *maladie de Chabert*, tried the effect of introducing the virus of hydrophobia into the torrent of the blood, by injecting it into the veins of a number of sheep and goats. To his delight he found that the same results followed the practice which had attended it in the *maladie de Chabert*. Animals which received the virus directly into their circulation, not only did not suffer the least inconvenience from it, but when subsequently exposed to repeated inoculations of hydrophobic virus, it produced on them no effect, while unprotected animals subjected to the same test, invariably succumbed to the disease. Hydrophobia communicated in the ordinary way is generally a long time before it takes a hold upon the system, and M. Galtier is at present endeavouring to ascertain whether by stepping in with his intravenous inoculation in animals which have been bitten by rabid dogs, he cannot anticipate and neutralise the natural development of the disease, as we can the slower development of small-pox infection by the more rapid action of vaccine lymph.

Another disease, which until within the last few years was, in this country, believed to be absolutely non-contagious is consumption, and yet it, and the whole class of tubercular diseases to which it belongs, have been proved to be eminently infectious. They have been transmitted from man to the lower animals, and from one lower animal to another. For some time back M. Toussaint has been engaged in investigating the subject. He tells us that a large number of the cattle sent to the slaughterhouse in France, suffer from the disease, and that the presence of tubercles in their lungs is not considered to render them unfit for human food; and I believe that the position of Great Britain in both these respects, will be found precisely similar to that of France. He found that by feeding pigs with the lungs of such animals, he produced tubercular disease in them. He found, by direct experiment, that the virus of the disease pervaded the nasal mucus and saliva, and that inoculation with either of these would reproduce it. In this manner he accounts for the spread of tuberculosis among pigs and cattle feeding from a common trough, and he assures us, that according to his observations, no contagious malady possesses a greater virulence. He found further, that the juices of the muscles were permeated with the infection, and that they too were effective for the propagation of the disease. Further, within the last few weeks, M. Toussaint has announced to the French Academy of Sciences, that he has succeeded in isolating and cultivating the microscopic organism which gives rise to tuberculosis, and after a series of cultivations in animal soups had reproduced tuberculosis with it on other animals. The important fact in connection with the organism is that it can stand a high degree of heat without perishing, M. Toussaint having succeeded in inoculating the malady from juice expressed from the steak of a tubercular ox, cooked so as to be but slightly underdone. If this be true, it affords us a certainty of at least being able to limit the ravages of human tubercular disease by directing our attention to what must be a most fruitful source of infection, namely, the sale of diseased meat. It does more. The first step towards success in dealing with a disease, is a knowledge of its exact nature, and that in the case of consumption, and the whole class of tubercular maladies has at length been achieved.

I might add various other diseases to the catalogue of those in which micro-organisms have, within a very recent period, been isolated, and shown by proof more or less conclusive to be the potential cause of maladies, in many of which their intervention was never suspected; but I shall confine myself to a single instance, illustrating quite another class of disease from those previously mentioned, which recent discoveries have proved to be due to a similar parasitic origin. I refer to ague. Ague has long been known to be associated with exposure to exhalations from marshy ground. Of late years it has been known that a microscopic organism—also a Bacillus—was to be found in the blood of persons afflicted with the disease. Within the last two

years Dr. Klebs, a German, who has done much work in this field, and Dr. Tomassi Crudelli, an Italian *savant*, associated with him in the investigation, discovered that by treating with water the soil of a fever-haunted marsh of the Campagna, the germs of an organism which flourished in the soil could be washed out, that germs of this organism floated—though in much smaller numbers—in the air which rested on the marsh; that by shaking it up with water, they too might be washed out, and that by repeating the operation again and again, an appreciable number of them might be collected from the air. Water suspending the organisms thus obtained, introduced into the circulation of a dog, produced ague more or less rapidly, and more or less violent, according to the numbers in which the Bacilli were present. This not only explains the nature of the danger encountered by persons exposed to emanations from marshy ground, but it shows why intermittent fevers so frequently manifest a new activity after operations, involving a disturbance of the soil, and it further renders apparent why it is that quinine, which is known to kill such organisms, is so invaluable a remedy and preventive against the effects of exposure to swampy malaria.

But *cui bono?* you may ask; of what advantage is all this knowledge, when, without possessing it, quinine has for years been known to be the appropriate remedy? In many forms of malarial fever the poison is too virulent, and the course of the disease too rapid for quinine to be of any use. It is as with infection, with the most active form of the organism of chicken cholera, or large doses of the Bacillus of splenic fever; the effects are too immediate and too terrible for routine medicine to be of any avail. But, guided by exact knowledge, you can go straight at the source of the mischief. With this object Dr. Déclat, to whom I have before referred, suggested the vigorous use of phenic acid, by injection into the veins and otherwise, as a means likely to prove effective against the organisms of yellow fever, and kindred acute forms of malarial poisoning. The suggestion went out to Brazil, and in June last M. de Lacaille, a French physician resident in Rio, wrote home his experience of it. The first case on which he tried it, was a young lady apparently on the point of death, from the worst form of the disease, a fever attended with the fatal black vomit. In three days she was out of danger. "During the thirty years in which I have been employed in fighting yellow fever," writes M. de Lacaille, "this is the first patient whom I am certain of having snatched from death at such a period of the disease. In a dozen other cases the treatment was crowned with equal success, but in most of them," adds M. de Lacaille, "the cure was so rapid that notwithstanding my long experience, I have asked myself if they could really have been yellow fever. Called in at the period of incubation the triumph is easy."

Did time permit, I might quote other instances in which within the last few months, the specific organisms which constitute the potential cause of diseases of mankind and the lower animals, have been successfully isolated and cultivated in artificial media. I might tell you of the researches of M. Pasteur with regard to boils and puerperal fever. I might describe the important discoveries of M. Talamon with respect to diphtheria—how he has succeeded in isolating and cultivating the organism which occasions it—how he has shown that it can be conveyed from mankind to various domestic animals, and from domestic animals back to man; and how these facts explain many features in the history of diphtheria contagion hitherto inexplicable, and present to preventive medicine a new indication for the limitation of this terrible disease.

STEPS have been taken to found a cottage hospital at Harrogate. The proposed building will, it is hoped, if the necessary funds are forthcoming, include all modern appliances, and will accommodate sixteen patients. The site, consisting of nearly 3,000 square yards, has been presented to the committee by Mr. F. B. Greenwood, and £1,000 has been given by a benevolent donor.

GUN-SHOT WOUND THROUGH THE RIGHT LUNG—RECOVERY.

By JOHN D. HILLIS, F.R.C.S.I., M.R.I.A.,
British Guiana.

DURING the temporary absence of Dr. Bolton, at whose house I was staying, I was called on the night of the 12th of August last to James Leonard, *æt.* 15, a collier's son, residing in a bleak, mountainous district, Clonbrock, Queen's county, who was shot during some disturbance, it is alleged, in connection with the process of "Boycotting."

The injured boy was lying in a hovel surrounded by a crowd of sympathisers. He was in a state of collapse, with a rapid, feeble pulse, and sub-normal temperature. The wound of entrance was situated between the cartilages of the 4th and 5th ribs on the right side, corresponding to which was a hole in the shirt from which the piece was missing. The probe readily entering from before directly backwards. On turning over the patient and relaxing the parts, I could detect the bullet lying beneath the muscles at the side of the scapula. Air and blood bubbled from the wound at every expiration, and there was general emphysema of that side of the chest, extending up the neck. I administered restoratives, &c., extracted the bullet and a piece of cloth, and the patient was made to lie on the wounded side, with the wound dependent. The latter was not allowed to close, iced cloths were applied firmly to the chest, and iced milk and barley water ordered; subsequently, the chest, except around the wound, was strapped.

On the third day all danger of internal hæmorrhage had so far passed, but pleurisy set in. On the seventh day pneumonia was superadded, the dulness extending over the lower part of the lung, and some distance above the wound line. Quinine in three grain doses, every three hours, with hot linseed poultices did well, but large quantities of stimulants had to be given.

On the seventeenth day symptoms of cardiac embolism threatened, and the case nearly terminated fatally, but the administration of ammonia caused a rally. The pulse for several days was 144, and 120 for several weeks. The temperature, which was only occasionally taken, ranged up to 101 deg. F.

Dr. McDowel, of Carlow, kindly saw the case with me on one occasion, and as dulness persisted, a blister was applied with benefit. The bullet was from a Colt's revolver, and weighed three drachms. Leonard is now convalescent and able to be out, some pleuritic thickening merely remains.

THE PRESENT STATE OF LEGISLATIVE AND OTHER TREATMENT FOR THE HABITUAL DRUNKARD.

By NORMAN KERR, M.D., F.L.S.

THE issue of the persistent agitation, under the successive guidance of the late Donald Dalrymple and Stephen Alford, carried on by the Social Science Association, the British Medical Association, and the Society for the Promotion of Legislation for the Control and Cure of the Habitual Drunkard. The real merit of the Habitual Drunkards' Act, 1879 is, that for the first time in British legislation there has been affirmed the principle of the compulsory detention of the habitual drunkard for curative purposes.

The confirmed inebriate must, when in his or her sober senses, voluntarily appear before two magistrates and confess himself in writing to be an habitual drunkard within the meaning of the Act. How this provision impairs the usefulness of the measure is but too well known to those who are consulted medically in these distressing cases. The friends invariably shrink from publicity, as the publication of an application from a dipsomaniac for detention in a Retreat casts a slur on the applicant and on all his family connections.

The Act will expire in eight years, having been in operation for two years. The whole period was so short that it afforded little inducement to anyone to sink the amount of capital indispensable to the equipment and maintenance of an adequately appointed Retreat. The result is, that at the present time there is only one Retreat, licensed under the provisions of the Act, that I can recommend. At this establishment the lowest rate is £3 3s. per week.

Thus there is no city of refuge, no secure haven, to which the ordinary police court or impecunious dipsomaniac may for a time consign himself, where he will be in circumstances favourable to cure by the exclusion of the narcotic alcoholic poison which has been the cause of his undoing.

The Dalrymple Home.—Impressed with the urgency of the case of the habitual drunkard with no means at all, or even with moderate means, a project, emanating from a public meeting at the Mansion House, London, under the presidency of the Lord Mayor, has been set on foot for the establishment of a model Retreat under the Act.

It is worthy of note that a preliminary condition is that no member of the Committee of Management will be allowed to derive any pecuniary profit from the undertaking. The scheme is intended to be enrolled under the charitable provisions of the Limited Liability Act, and no contributor can receive any financial return for his contribution, any profit made going to the extension of the work. Some £2,000 has been already promised, but £2,000 more is needed before a suitable house and grounds can be acquired.

If we can succeed in demonstrating that we have cured a number of typical cases of habitual drunkenness, the Legislature will not only permanently renew the Act at the expiry of its term, but probably so improve its provisions as greatly to extend its usefulness.

The British Medical Association, desirous to provide an opportunity to dipsomaniac paupers to avail themselves of the provisions of the Act with a view to reclamation, recently communicated with the Local Government Board and with Boards of Guardians throughout the kingdom. No definite promise to do anything was elicited from the former. As regards the appeal to the guardians, while some boards were desirous to have the power, if they should think fit to exercise it, to pay for the detention of pauper habitual drunkards in Retreats, the majority of the boards did not wish for any power to enable them to add to the rates for the poor.

There are homes, on a more or less expensive scale, for the reformation of female inebriates, but in none of these has it been deemed needful to apply for a license under the Act, the curable inmates having generally been found desirous to voluntarily remain till cured. Accusations have been made as to mismanagement and ill-treatment, which, so far as I can see from personal investigation, are mostly without foundation, and which have tended to invalidate the success which has rewarded the praiseworthy and philanthropic efforts of the promoters of these institutions.

But the inquiry I have made has convinced me of the desirability of governmental inspection of all such places as are supported wholly or partially by public subscription. An accurate record should be kept, in a book, of the particulars of each case, the treatment while in residence, and the after history, so that the successful treatment pursued at the Home may be available for purposes of public usefulness. The managers of reformatory institutions should welcome official inspection as affording the best guarantee of sound management and the most effectual reply to accusation and inuendo.

At present there is ample accommodation at excellent private establishments for the wealthy dipsomaniac, but for the habitual drunkard in moderate circumstances, or in a state of destitution, there is no provision whatever. Magistrates, clergymen, and medical men are constantly calling for inebriate Retreats, which they could speedily fill with suitable inmates. Shall the appeal of men so

well qualified to form a sound judgment be unheeded? Can we turn a deaf ear to the distressful and despairing cry of so many victims to our national vice, whom a little money and a strong hand might, by such Retreats as those whose cause I plead to-day, transform from paupers to ratepayers, from drones to workers, from disease to health, and from misery to happiness?

Clinical Records.

GUNSHOT WOUNDS AMONG MEN OF THE ARMY HOSPITAL CORPS AT MAJUBA HILL.

Reported by Surgeon-General LONGMORE,
O.B., Q.H.S., F.R.C.S.,
Professor of Military Surgery in the Army Medical School at Netley.

Case of Corpl. Farmar, A.H.C.—This man was attending to the wounded on Majuba Hill under the direction of Surgeon Landon, when the Boers, having gained the summit, directed a fire upon the troops who were retreating past the spot where some of the wounded had been collected. Surgeon Landon, who with his assistants remained with these disabled men, was shot as well as some of the disabled men themselves. Corpl. Farmar then held up in his right hand a bayonet with a triangular bandage attached to it as a signal to the Boers, who are believed to have been about fifty yards off, that they were not combatants. He was almost immediately struck by a bullet in the forearm. He next, saying he had still another arm, held up the extempore flag of truce with his left hand; but this arm was also directly hit. In the first of the two wounds the bullet struck and partially fractured the right ulna on its inner aspect just above the styloid process, injured the ulnar nerve, and tore its way out by the base of the metacarpal bone of the little finger. Sensation in the parts supplied by the palmar branches of the nerve still continues dull and imperfect. The cicatrix of the wound adheres to the bone, and is tender on pressure. In the second wound, that on the left arm, the bullet entered in front just above the bend of the elbow-joint, partially fractured the humerus near its inner border, and escaped just behind the prominence of the inner condyle. The ulnar nerve on this side was completely severed, and he has never had any sensation in the parts supplied by the nerve below the wound since. When the bullet passed the limb he felt as if he had received the shock of a strong electric battery, and the hand and arm remained quivering and very painful afterwards. The hand and forearm are much wasted. The little finger is strongly contracted, and in addition to total loss of sensation in the little finger and ulnar side of the ring finger there is marked diminution of temperature in these situations. Owing to alterations of shape in the lower part of the humerus, the result of the gun-shot fracture, the elbow is permanently contracted. The forearm can be flexed on the arm fully, but cannot be extended beyond an angle of forty-two degrees. The injuries disable him from ordinary manual labour.

Case of Private Sealey, A.H.C.—Private Sealey was half kneeling, dressing a wounded man of the 92nd regiment, when a bullet struck and passed through him near the left shoulder. The wound of entrance was two and a quarter inches above the top of the anterior fold of the axilla, one and a half inches below the coracoid process; that of exit was nearly directly opposite, about two inches above the posterior axillary fold. The axillary nerves appear to have escaped entirely. He merely felt a blow locally, and, not realising the fact that he had been shot, went on bandaging the patient. The bullet must have been a rifle bullet of narrow diameter and armed with a very high velocity, for the cicatrix of the exit opening is exactly similar in

size to that of the entrance wound, viz., $\frac{1}{2}$ inch in diameter. Within a minute or two after receiving this wound and while still dressing the patient he was struck by another bullet in nearly a corresponding place on the right side. This bullet entered just below the acromioclavicular articulation, between it and the coracoid process, nearly four inches above the top of the anterior axillary fold, passed downwards and backwards, and escaped at the inferior margin of the scapula, about $2\frac{1}{2}$ inches above its inferior angle. A small gap remains in the border of the scapula, where a piece of bone appears to have been punched out. During the healing process some small fragments of bone escaped by both openings. - The instant he was hit on this side, the man felt pain through the whole limb, and his arm dropped useless by his side, so that the nerves were evidently injured by the passing projectile. They have since recovered their function, but owing to cicatricial contractions, the arm remains seriously disabled. He cannot extend it above an angle of 45 degrees from his side, and all the movements of the shoulder are impaired. The left arm is also weak, and any attempt to elevate it above the level of the shoulder causes much pain. The injuries just described were aggravated by the colonial ambulance waggon, in which Sealey, and several other wounded men, were being brought down from Mount Prospect Hospital, becoming overturned on the way. Private Sealey was much bruised about the chest at the time of this accident. It is remarkable that in each of the two wounds, close as they were to the articulation, the joint itself should have escaped from being opened. From both wounds being so nearly on the same level, so close to each other, and following in such quick succession, it was probably the same Boer who fired both shots. It is not unlikely that Corporal Farmer's wounds were also inflicted by one man.

I am tempted to add the following anecdote, which has not hitherto been made public, regarding Surgeon Landon, of the Army Medical Department, who was mortally wounded on the same occasion. It not only illustrates the immense value of the subcutaneous injection of morphia in certain cases in field practice, but affords additional testimony to that which has been already published regarding the cool and thoughtful character of that much regretted young officer. Surgeon Landon was kneeling, attending to a wounded man, when a bullet wounded him in the loin, and he at once fell forward. The lower half of his body at the same time became completely paralysed. Dr. Landon at once recognised the nature of his injury, and told Corporal Farmer he must die. After the firing had ceased some Boers came down among the wounded, and, with them, a man who said he was a doctor. At this time Corporal Farmer, who, as before mentioned, had both ulnar nerves injured, was suffering excessive pain in the two arms, and Dr. Landon, who had brought in a field case, which he had carried, slung from his shoulder, some morphia solution and syringes, advised some of the solution to be injected for its relief. The Boer doctor attempted the operation in one arm, but, from the bungling way in which he set about it, it was evident the proceeding was not familiar to him. Dr. Landon then caused the upper part of his body to be propped up against a boulder of rock, and in that position administered the morphia injection in both Farmer's arms in succession. The result was the Corporal obtained such relief from the pain that he shortly afterwards, in spite of the rain and general discomfort, fell asleep, and remained so for several hours. When all the circumstances of the occasion are remembered, it is difficult to imagine a more perfect example of professional heroism than was afforded by the conduct of Surgeon Landon from the time when the Majuba fight commenced to that when death put an end to his own sufferings.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

THE first meeting, after the recess, of the Clinical Society of London, was held on Friday Evening, Oct. 14, when the President, Prof. LISTER, F.R.S., took the chair, and announced that the following distinguished foreigners had been proposed by the Council for election into the society as honorary members, viz.,—Drs. Bigelow and Billings from America; Professors Esmaroh and Volkmann, from Germany; M. Pasteur from France; Drs. Pantaleone and Maszoni from Italy.

Dr. WILTSHIRE ON

A CASE OF TRAUMATIC RUPTURE OF AN OVARIAN CYST.

A lady, *æt.* 28, just convalescent from typhoid fever fell, while in a hansom cab, struck her abdomen and burst an ovarian cyst which she had had about three years. Severe shock and collapse ensued; but under opium and restoratives she slowly recovered; and two years after the accident remained quite well and free of her tumour with the exception of a small mass, supposed to be the remains of the collapsed cyst and pedicle. Though an expectant plan of treatment was elected in the belief that no hæmorrhage was going on, yet the propriety of immediate operative interference was discussed chiefly in relation to the question of rapid death from internal hæmorrhage, and its arrestment by means of abdominal section, accompanied, of course, by removal of the ovary. Operation in connection with ruptured dermoid purulent, infective, or strangulated (twisted) cysts, and peritonitis was also referred to; and allusion was made to the treatment of dangerous intra-peritoneal hæmorrhages from ruptured ectopic gestation, varices of the broad ligament, ruptured uterus, &c. The prognosis in rupture of infective ovarian growths was adverted to, and the views of pathologists and surgeons thereon respectfully sought.

The PRESIDENT expressed regret, that no discussion had ensued on the paper, since the case described was one of an important class which caused much anxiety to the practitioner in charge, in respect to treatment. The necessity arose in such cases to determine with accuracy, whether the cyst was uni- or multi-locular, whether of the broad ligament or of the ovary itself involving the whole structure. Whether however removal or delay on the chance of subsequent absorption should be pursued, would require to be decided by the experience of the attendant. He thought it a remarkable fact that such a solid mass as Dr. Wiltshire described, should have dwindled away as it had.

Dr. WILTSHIRE explained that he had laboured under the disadvantage of never having seen his patient until after the occurrence of the accident. Dr. Oldham had previously diagnosed the tumour as a multilocular cyst, an opinion also arrived at by others who saw the case. Reinfection, continued Dr. Wiltshire, does undoubtedly occur in some such cases, and may arise from an after growth. He would have been glad to have had surgical estimates of the necessity for operation.

Mr. CHRISTOPHER HEATH ON

A CASE OF LARGE ODONTOME REMOVED FROM THE LOWER JAW.

This was one of the rare tumours described by Broca as *odontomes odontoplastiques* and consisted of a mass of dentine studded with nodules of enamel. The mass weighed 815 grains, and measured $1\frac{1}{2}$ by $1\frac{1}{2}$ inches. The patient was a young lady of 18 who had never been able to close the teeth properly, but otherwise was supposed to have gone through the first and second dentitions naturally. Last Christmas, she had some pain and uneasiness about the right angle of the lower jaw, and in April, her father, a dental surgeon, extracted the second bicuspid tooth, there being no molars then present. A dentist, who was subsequently consulted, thought he detected an encysted tooth, and tried to extract it with the elevator. The result was an acute attack of periostitis. Profuse suppuration ensued, and on firm pressure near the angle pus could be forced up from the interior of the bone. Under treatment, the inflammation subsided, and the patient went to the seaside, and on her return there was apparently some exposed bone with greatly hypertrophied mucous membrane on each side. A month later, after imprudent bathing, sudden increase of pain and swelling took place, and

she consulted Mr. Heath, who found great enlargement of the bone with a fungus-like growth in the mouth, and apparently bare bone, the appearances closely resembling those ordinarily found in a case of sarcoma of the jaw. An operation involving removal of a portion of the jaw was declined, and the swelling slowly diminished again. In September Mr. Heath undertook an operation for removal of the supposed sequestrum of bone, and after considerable trouble succeeded in elevating the mass described from its bed, since which the jaw has slowly contracted to its proper shape.

The PRESIDENT observed that much interest attached to the case both practically and pathologically: practically, because an apparent second growth was removed by simple extraction; pathologically, because of the curious, essentially tooth-like structure of the tumour. The class of cases was rare, but it was necessary always to be on guard against errors of diagnosis in regard to them.

Mr. KEETLEY showed a patient suffering from

CHARCOT'S JOINT DISEASE.

The case was that of a shopkeeper, Mr. J. P., *et.* 34, married ten years, having three healthy children. Up to October, 1880, no other symptoms than the following had been noticed: (1) slight "weakness on the legs," of twelve years' duration, and attributed by the patient to the lameness occasionally produced by a "corn" beneath the right great toe; (2) pains in the muscles described as "rheumatic;" (3) attacks of diarrhoea, occurring fortnightly for long periods at a time. But, in October, 1880, the "corn" ulcerated, and the corresponding great toe became greatly swollen. About a week afterwards, the hip, groin, and thigh of the same side (the right) swelled enormously, but was pale and comparatively free from pain, *i.e.*, such pain as did exist was not synchronous with the occurrence of the enormous swelling. A deep fluctuating point being opened towards the lower part of the front of the thigh, several ounces of synovia, or a synovial-like fluid, escaped. In two months the patient was able to stand again and move the joint freely; but there was then discovered $1\frac{1}{2}$ inch shortening, a tendency to eversion, and a peculiar "scrunching" or crepitus on manipulating the hip in a certain manner. The joint was also somewhat loose. Apparently, the head of the femur had disappeared. From this time, for nine months, the limb steadily increased in uselessness, the powers of spontaneously rotating it both inwards and outwards seemed to also return. But then the left hip was attacked exactly like the right, but not so acutely. This attack came on whilst the patient was being severely purged by two pills and two black draughts prescribed by a chemist on a theory that the patient looked "bilious." While the swelling of the left hip was subsiding, after the manner of that on the right side a year before, severe pains attacked the front and inner side of the left thigh, and the left knee also, but passed away after some hours. At present the patient has only occasionally slight pains in the left thigh, but great numbness on the front aspect above the knee. He can already get about on crutches, and even stand without them. There is now evidence of the left hip having undergone anatomical changes like those of the right. The right great toe joints are also deformed since the swelling thereof twelve months ago. The "corn" is represented by a thin red scab. There are various symptoms of *tuberculous dorsalis* besides those above-mentioned. There are loss of patellar-tendon-reflex, of iris reflex, of the power of standing with the heels together and the eyes shut, partial loss of sensation in the outer sides of both feet, perverted sensation in the right foot, slight deafness of the left ear, and (?) an staxic gout disguised by the joint affections. And, though there are no gastric crises, there are what might be termed "intestinal crises"—*viz.*, the above mentioned periodical attacks of diarrhoea. In the case of each hip, the subsidence of the general swelling left a marked enlargement of the inguinal glands which persisted some time. The internal treatment has been iodide of potassium with salicylate of soda, 5 grains each, three times a day. Is it justifiable to try nerve-stretching in this case? These are the following grounds for entertaining such an idea. In most of the cases, now not few in number in which nerve-stretching has been done for the lightning pains, general, as well as local, benefit has accrued not only by way of lessening the pain, but also by diminishing, or even removing, the inco-ordination. And the same general improvement as regards the whole neurosis, has been observed in leprosy, when the pains of that dis-

ease have been treated by nerve-stretching. Done antiseptically, it is by no means a very serious proceeding. Moreover, to do nothing in such a case as this does not secure for the patient a very good prognosis. If the speaker had any evidence to show that nerve-stretching had checked the visible changes in the skin in leprosy, he would be still more inclined to try it. Could any of his hearers speak as to that point?

Dr. DYCE DUCKWORTH said these cases were more common in France than in this country, his own search after them being rarely successful. Sir James Paget failed to find a single specimen illustrative of the pathology of the disease in all his extensive museum experience. The ulceration Dr. Duckworth considered to be examples of that peculiar kind of sore described by Dr. Ball, showing special features of its own. Nerve-stretching he continued, had its advocates and its opponents, Erb being among those who scoff at its efficacy. At the recent Congress, however, it was held in favour by a majority, especially in cases of severe pain.

Dr. BUZZARD referred to cases reported to the Society about ten years before, in which the peculiar ulceration described by Dr. Ball had been exemplified. It was a trophic change connected with disease of the nervous system. The patient exhibited by Mr. Keetley had suffered from paroxysms of diarrhoea for ten years, having three or four liquid motions daily. He suffered also from heart-burn, but was not troubled with vomiting. In February, 1880, he (Dr. Buzzard) had suggested a relation between such cases and gastric crises; several cases of arthropathy in his own practice illustrating the truth of this conclusion. He thought it of interest to consider whether the *intestinal* evils named in the paper might not be secondary to gastric irritation through the influence of the vagus. Sclerosis of the posterior columns of the cord might be continued up to the medulla oblongata, and so affect the track of the pneumogastric nerve. He had formerly suggested the possibility of a centre in the medulla, of which the function was to preside over the joints, whereby might be explained the joint affections sometimes occurring in heart disease and rheumatic fever. Charcot's suggestion, he urged, was not borne out to the effect that in arthropathy the anterior cornu of the cord is the affected part. Also, in these cases the muscles preserved electric irritability; and in one case, shown by himself, that of a woman, the shoulder muscles were enormously developed, although the early signs of arthropathy had evidenced themselves. He imagined the condition described in Mr. Keetley's case might be due to vagus irritation upsetting the intestinal canal.

Dr. ALTHAUS commented on the remarkable feature in the case presented by the oedema of the joint, the swelling in such cases being usually *hard*, and not oedematous. He could not quite endorse Dr. Buzzard's explanation of the intestinal crises, for while gastric crises in nervous diseases were not uncommon, the particular form known as Charcot's joint disease was most rare. The theory propounded by Dr. Buzzard with regard to a special centre in the medulla he regarded as ingenious, but, to the present, unproved. The large cells described by Charcot as existing in the anterior cornu of the cord were not found on post-mortem examination. The pathology of the disease was, however, obscure. Volkmann suggested that it might be due to injury received by staxic patients; but this could not be held, because the special joint affection was frequently determined at a very early stage of the disease. Nerve-stretching, Dr. Althaus urged, in conclusion, should be resorted to only as a last experiment.

Mr. H. PAGE said that until recently the Royal College of Surgeons possessed no specimen of the disease under discussion. Notwithstanding, however, he did not think the disease so rare in this country as was imagined; and several cases had been noticed in London hospitals within the last few years. Mr. Macnamara showed two cases at the late Congress; and in St. Mary's Hospital not long ago, he (Mr. Page) had a patient who said he suddenly felt one leg become three or four inches shorter than the other, no pain attending the change, and he himself walking some miles after it, the affection only being recognised on his reaching the hospital. Mr. Page had also had a private case. The disease does not necessarily attack large joints—a fact which might account for many instances being overlooked. In one of his patients in the out department of the hospital one foot was observed to swell; the tarsal bones subsequently enlarged, were freely movable without pain; and after some time sores appeared,

which the patient described as "gathered corns," and which, while looking very bad indeed, were not at all painful. This patient had a doubtful history of syphilis, but possessed well-marked symptoms of tabes dorsalis. In from three to four months the swelling subsided, the bones became ankylosed and reduced in size. The other foot underwent similar changes, ushered in by the sudden giving-way of the ankle, and followed by the characteristic series of phenomena, the foot ultimately feeling like a "bag of bones." One foot having spontaneously recovered, the second was left to Nature also; and in time the patient so far recovered as to be able to leave the hospital, having on a plaster of Paris bandage. Gastric and intestinal crises had attended the case, and also profuse hæmaturia. Mr. Page thought that cases should be carefully looked for, and that, as in the patient exhibited, no ataxic gait might be apparent.

The PRESIDENT observed that the affection was both remarkable and obscure, but still it seemed strange that the College of Surgeons possessed no specimens to illustrate it. Moreover, it was not so very rare. A case had been seen in King's College Hospital not long ago. Possibly, he suggested, it might not be considered a fit subject for museum collections.

Mr. KEETLEY considered that life might for years be compatible with the existence of ataxy, and the affection of a centre in the medulla. He found only one out of twenty-three recorded cases in which both hip-joints had been affected in same individual; but, notwithstanding, symmetry was a feature of the disease; and in twenty-three cases, where other than the hip-joints were affected, the symmetrical disposition prevailed. The disease itself was unmistakable; and he considered that Charcot's supposition, to the effect that it always had existed but was not common, had been confirmed by his own cases. The swelling described in the paper came on, without pain, in a week, and went away after two months, leaving the joint permanently affected. He had recognised the disease from a specimen in the temporary museum at the Congress, and could not regard it as a new one in any sense.

SOCIAL SCIENCE CONGRESS.

PUBLIC HEALTH SECTION, TUESDAY, OCTOBER 4th.

Dr. CAMERON, M.P., President.

THE first question for consideration was—

IS IT DESIRABLE THAT HOSPITALS SHOULD BE PLACED UNDER STATE SUPERVISION?

Dr. J. W. Moore read a paper by Mr. Henry C. Burdett, of which we gave an abstract in our last.

Mr. Collins, hon. secretary, read a paper on the "Hospital Administration in Paris and London," by Dr. Prespere de Piétra Santa of the city of Paris.

Mr. Shackleton was of opinion that there are too many hospitals in Dublin, and that some of them are competing with each other. He was in favour of general supervision of hospitals. The Municipal Council of Dublin made grants to several hospitals, and they consider that they ought to have more control over these than they possessed.

Mr. Peyton, Registrar of the Orthopedic Hospitals, Dublin, said State supervision implied State support.

The Rev. Dr. Haughton, F.R.S., remarked that State inspection had a tendency to degenerate into routine. The London hospitals suffered from an enormous plethora of income, which was often spent on objects outside the welfare of the institution. In the Dublin hospitals they were very poor, and in consequence all the virtues of poverty and adversity were developed. The governors did not interfere, because they knew that everything was done for the poor and for economy. In some of the hospitals the medical element was too strong in the management, and the public were under the impression that the hospitals were worked too much for the medical schools and too little for the patients. In Paris the hospitals had the incalculable advantage of ladies who devoted themselves from pure charity to the nursing of the poor; and the same was the case in the Catholic hospitals of Dublin. He thought that a strong representation of subscribers and a limited representation of the medical faculty on the management would be better than State supervision.

Surgeon Myers, Coldstream Guards, said that in Dublin, where the hospitals had not sufficient money, the State might grant it, and exercise supervision accordingly.

Mr. Clarendon, Honorary Secretary of the Adelaide Hospital, was in favour of some State supervision of hospitals.

Dr. Jacob said that in Dublin hospitals the cost per bed varied between £46 and £90, and of that the proportion spent on the patient himself was between £18 and £21. The mode of appointing the medical staffs needed improvement. He thought all charitable institutions should be under State supervision.

The Registrar-General, Dr. Grimshaw, said appointments were made in the most irregular and extraordinary manner in the Dublin hospitals, and some were even sold to the highest bidders. Religious and political considerations also came in, and the best man was not always selected. He was not an admirer of the existing Board of Superintendence of the Hospitals in Dublin, but it had done a great deal of good. There were thousands of scandals that never came before the public. He was in favour of State supervision, which could be reviewed by Parliament.

Dr. Cameron, Medical Superintendent of Health, Dublin, was in favour of an independent supervision over the administration of all public hospitals, such as the Local Government Board exercises over the hospitals under the Poor-law, and moved that the council be recommended to take measures to promote an inquiry with a view to securing such supervision.

Dr. Darby seconded the resolution, which was unanimously agreed to.

The next paper by Major F. Duncan, LL.D., on

FIRST AID TO INJURED PERSONS,

was read for the author by Mr. F. R. Davies, K.J.J., president of the Dublin centre of the St. John Ambulance Association. The paper referred to the introduction into England by the Order of St. John of improved vehicles for the transport of injured persons. From this had sprung the existing St. John Ambulance Association, branches of which existed in Great Britain, Ireland and the Colonies, and which has already instructed over 80,000 pupils of both sexes and all classes in the first treatment of injured persons.

The chair having been taken by the President of the College of Surgeons (Dr. Chaplin, of Kildare).

The President of the section (Dr. Cameron), read a paper on

ANIMAL VACCINATION,

of which we shall publish an abstract in our next.

Dr. Haughton said the paper was a very valuable one. There was no doubt that the death-rates amongst vaccinated persons had varied since the commencement of the century. The mortality amongst unvaccinated persons was smaller now than formerly. The question now was not as to the desirability of vaccination—for only lunatics doubted that—but as to how it could be made most effectual. He believed in compulsory vaccination, but that every person should possess the right of choosing between humanised lymph and calf lymph.

The Registrar-General believed that vaccination was not as protective as it might be made.

The Chairman was of opinion that vaccine lymph was not now what it used to be thirty or forty years ago. He believed we should revert to the original source from which Jenner derived lymph.

WEDNESDAY, OCTOBER 5.

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASE.

The special question for discussion was—Is it desirable that there should be a system of compulsory notification of infectious diseases; and if so, what is the best method of carrying such a system into effect, and what is the best mode of enforcing the isolation of cases of infectious disease?

Mr. Collins read a paper by Mr. Michael, Q.C., on the subject. After giving a summary of the Bills introduced into Parliament last session for the compulsory notification of infectious diseases by Mr. Hastings for England and Mr. E. D. Gray for Ireland, the paper mentioned that the British Medical Association intend next session to introduce a bill differing from the two just mentioned in this respect, that it will propose that the medical attendant shall deliver a certificate of the presence of infectious disease in any house to the occupier instead of directly to the sanitary authority of the district in which the house is situated. It was desirable, the author thought, that a select committee of the House of Commons should be appointed.

Dr. J. W. Moore read a paper on the subject. The author pointed out that "notification" and "registration" should not be used as synonymous terms. Two things would seem to be necessary in the case of outbreaks of epidemic infectious diseases first, the immediate compulsory notification of such outbreaks to the sanitary authorities; secondly, the early registration of all cases of these affections, and the publication of the tabulated results at frequent intervals by the general registration offices of each division of the United Kingdom. Whatever system of notification is finally adopted should apply uniformly to the whole country. Four methods have been suggested or adopted, viz., 1. Direct notification by the medical attendant to the sanitary authority; 2. Indirect notification, by the medical attendant giving a certificate to the head of the family; 3. Notification by

the head of the sick person's family or the occupier of the infected house; 4. Dual notification by both the medical attendant and the head of the family or occupier to the sanitary authority. Dr. Moore expressed himself in favour of a modified system of indirect notification by the medical attendant, in accordance with which it should be incumbent upon the sanitary authority to acknowledge at once to the medical attendant the receipt of the information from the head of the family, the medical attendant to send a duplicate certificate to the sanitary authority should their acknowledgment not reach him within a short specified time.

Dr. Stewart Woodhouse read a paper on the same subject. The writer, while recognising the desirability of reporting to the sanitary authority every case of infectious disease, believes that the measure introduced to the House of Commons last session for this purpose would meet with the strenuous opposition of the medical profession, who should be the chief machinery in executing it—on the ground that it would violate the secrecy due to their patients. Consequently, he proposes that all medical men shall be required, when they have decided that a case they are attending is an infectious disease, to notify to the sanitary authority that they are attending a case of this nature in such and such a street, square, road, &c. (employing the municipal designation), and also stating whether the room occupied by the patient is inhabited by anyone save that patient's nurse. If not inhabited by anyone save the nurse, the sanitary authority shall interfere no further. But if the certificate shall state that it is occupied by other persons then the sanitary authority shall have power to write to the medical attendant, asking him for the name and address of the sick person, which he shall then furnish.

Dr. Jacob regretted that he had to assume a position of uncompromising antagonism to the system of infectious notification which had been proposed to them. He did not hesitate to admit fully the advantage to be gained by the notification of infectious diseases. His quarrel was with the way in which the papers proposed to carry notification into effect. He asserted that that mode was inquisitorial, arbitrary, and inconsistent with the liberty of the subject. It would require the householder to notify at a moment when his heart and mind would be occupied with the condition of some dear one. The powers existing under the Public Health (Ireland) Act were not very extensive, but still the consequences following disobedience of its provisions were very serious indeed. He was not satisfied that these regulations were necessary, but they were nothing in comparison with other propositions which sanitarians were asking them to adopt in connection with the compulsory notification of disease. The latest bill on the subject had been promulgated by the corporation of Salford. Under that bill power was sought, not only to close any place where infectious disease was, but even schools and places of public resort in its neighbourhood, and also any dairy or place for the sale of provisions where infectious disease existed; and power was sought to declare that where a house was infected no person in it should exercise any occupation, or handle any food or beverage, or work in the company of infected persons. If such powers were exercised in a city like Dublin, where there were instances of so many as seventy people being occupants of one house, the daily bread of all these people might be stopped. These were some of the vagaries of sanitarians, although he did not say they were included in the propositions before the section. But he objected to the latter on the ground that they would defeat the very object which it desired to accomplish. If the onus of notification were put on the physician it would be a direct inducement to the patient to avoid calling him in until the last moment, because by doing so he would bring to his home the whitewasher of the sanitary authority, and a disturbance of domestic arrangements which, in the case of schools and hotels, would involve ruin. Consequently the case of infectious disease would remain fruitless. The Public Health Committee of the Corporation had admitted the existence of this feeling, and that in consequence of it, practitioners were called in who treated infectious disease behind backs and said nothing about it. Occupants of tenements also feared incurring the censure of their landlords by making known the existence of infectious diseases in their dwellings, and they dreaded being removed to the hospital. Therefore, if compulsory notification became the law, they would resort to quacks, unqualified practitioners, and learned old women. On the other hand a system of voluntary notification actually existed at present which was working well. The medical profession did not resist what was proposed from mere pocket interest, but because they believed it was against the feelings of the population, and that it would not work at all. At the same time they felt that it was outrageous that the confidence reposed in the physician should be forced for public use without the consent of his patient, and without adequate remuneration. The effect of the plan would be to throw attendance on the sick into the hands of practitioners of doubtful morality who would not tell the truth. He objected also to physicians being made to dance attendance in police offices in order to carry out this law. He had not mentioned a variety of other ways in which it would be prejudicial to the medical profession. In order to ascertain what

the opinion of the profession generally on the subject was he issued 1,800 circulars. To these he received 800 replies, of which 792 were dead against the medical man taking any part in written notification, and the remaining eight for a modification of the proposition. The College of Physicians and Surgeons had both pronounced against it.

Mr. Hastings, M.P., said he remembered a large number of reforms which proved to be for the good of the public, and he never knew one of them that had not been opposed on grounds that afterwards turned out to be unsubstantial. All the arguments that were now used against compulsory notification of infectious diseases by medical men, were also used against the registration of deaths, yet the latter practice had not been productive of evil to the public.

Mr. E. D. Gray, M.P., said that as he introduced the Notification of Diseases (Ireland) Bill, which had been referred to, he wished to say a few words. Dr. Jacob seemed to be an opponent of the principle of notification altogether.

Dr. Jacob—No, no.

Mr. Gray said he was glad of that. They had then a consensus that some form of notification was desirable. Let them start from that point. Was the duty to be thrown upon the householder or the medical man? He framed his bill on the principle of requiring the medical man to give the information, because he held that infectious disease was very much like a fire. If notice of it was not received at once it could not be dealt with. While the medical man was serving the householder, and the householder the sanitary authorities, the valuable time during which the disease could be effectually coped with would be lost (hear, hear). As regarded the healthiest classes the bill would, in fact, not touch them at all. What had occurred in other places? Take Edinburgh where the Act has worked with beneficial effect, and the death rate has been largely reduced. The notice which the medical man served on the sanitary authority had on it the words "attention is not urgently required." If the patient were one who had ample means of treatment at his own house, the certificate went in that form and the sanitary authority practically took no action in the matter. If the patient were of circumstances of an opposite character the word "not" was struck out. If a compulsory notification act were in force in Dublin, all the notices the sanitary authority would take of cases of patients in different circumstances would probably be to send word that they could get linen washed more safely than at a public laundry. But if the case occurred in a poor tenement, of course, the sanitary authority would pay attention to it at once. On the other hand, if the system were adopted of making the medical man serve notice upon the head of the household, the latter might be an ignorant or illiterate workman who would not give information at all. If it were made the duty of all medical men to give the notification in question, there would be nothing invidious in it.

Dr. Cameron, Medical Officer of Health for Dublin, said that in this city forty per cent. of the deaths occurred in the tenemental dwellings from zymotic diseases. He maintained that notification by the medical man would in no way interfere with the comfort, liberty, or even sentimentalism of the patient.

Mr. Dalgleish, Town Clerk of Jarrow, said the system of compulsory notification, or the dual system, was established in that borough, in a very stringent manner, in 1878, and it had since worked admirably.

The Registrar-General, Dr. Grimshaw, supported the views of Dr. Moore and Mr. Michael. A case lately came to his knowledge of a boy selling toys in a shop while he had measles. It would have been perfectly justifiable to close that shop. The case of the medical man who complained of being injured by being obliged to notify the diseases of his patients came exactly under the same category. One point which he had not yet noticed was this: It would be of the utmost importance that where towns were in close communication with each other, as Dublin, Liverpool, and Edinburgh, the outbreak of an epidemic in one should be, as soon as possible, made known in the other. He did not believe the law in question would prevent medical men from being called in. A few persons might conceal infectious diseases, but that would be put an end to by a few of them being fined 40s. each in a police court.

Dr. Chaplin, President of the College of Surgeons, said the medical profession approved of notification, but were opposed to being called on to make it on account of the position it would place them in with their patients.

Miss Downing, on her own part, and on that of the Vigilance Association for the Defence of Personal Rights, of London, by whom she had been sent as a delegate, declared herself strongly opposed to the bills of both Mr. Hastings and Mr. Gray.

The President in closing the discussion, remarked that the State had a right to expect duties from medical men in return for the monopolies which it gave them.

THURSDAY, OCTOBER 6TH.

OVERCROWDING OF DWELLING HOUSES.

The special question for discussion was—"Is any further legislation (desirable in order to more effectually prevent the overcrowding of dwelling houses?)"

The Recorder of Dublin read a paper on the question. It stated that the supremacy of the death-rate here lately compelled the speeding of a Royal Commission, and the very able report of the commissioners, Messrs. Rawlinson, C.E., and MacCabe, of the English and Irish Local Government Boards, unhesitatingly attributed this evil state of things to the condition of the houses of the poor. Previous to this report the Recorder had addressed the Lord Mayor on the supremacy of the city crime rate, attributing this also to the social condition of the poorer classes within their homes and in the streets outside. The author urged the reparation and reconstruction of the various statutory powers already existing under general acts, rather than seeking to deal with this ancient and diversified city upon any single or special plan. These statutory powers came under the heads of—1. Provision relating to the cleaning of entire civic areas; 2. Those relating to the reparation of individual houses; 3. Those relating to the provision, by civic authority, of houses for the working classes. The author expresses his conviction that the urban grievances which now call for redress are more urgent than those rural claims which have monopolised public attention.

Dr. Charles A. Cameron, M.D., S.Sc.C., Cambridge, Fellow and Professor of Hygiene, R.C.S.I., Medical Officer of Health for Dublin, read a paper on the question, in the course of which he referred to what had been done in the way of erecting dwellings for the labouring classes in a number of towns in England and Scotland. He stated that the loans advanced under the Artisans and Labouring Classes' Dwellings Improvement Act up to March 31, 1880, were: for England, £1,419,970; for Scotland, £115,000 and for Ireland, £80,500. Under the provisions of the Labouring Classes' Dwellings Act the loans raised in England and Scotland amounted to £394,741, and in Ireland to £86,654. The Corporation of Dublin have put in force the provisions of the Artisans' Dwellings Act. They have completely cleared away a collection of dwellings situated under unhealthy conditions, at a cost of £22,000, and they have let the cleared site to the Dublin Artisans' Dwellings Company at a rent of £1,200 a year. One of the most urgently required measures for the improvement of the sanitary condition of Dublin is the erection of a large number of dwellings for the lowest classes of the industrial population. The existence of such tenements would stimulate the owners or renters of the ordinary low-class tenemental dwellings to a healthy competition, which would be the means of causing a general improvement in the condition of the homes of the people.

The Lord Mayor said the Corporation were anxious to deal with the matter in the most comprehensive manner. His own knowledge of the subject enabled him to say that the cost of constructing labourers' dwellings was not such as to deter the Corporation from entering on the task. He believed sufficient accommodation could be provided at a cost to the citizens which would be fully recouped.

Mr. Collins, secretary to the department; Signor Pagliardini, Mr. Spencer, Mr. Wigham, Mr. Gray, M.P., Mr. Russell, Mr. Furlong, Mr. Carrol, and Mr. Thompson, having spoken, The Recorder replied.

Dr. Cameron also replied and said the Corporation had closed upwards of 550 houses, and had never given the owners any compensation.

On the motion of Mr. Collins the following resolution was passed, with one dissentient:—

"That it is the opinion of this section that it is desirable that the Corporation of Dublin should seriously consider the propriety of providing dwellings for the labouring classes under the provisions of the various Acts of Parliament relating thereto, and that the Council be requested to submit to the Corporation this expression of its opinion."

A paper by Edwin Chadwick, C.B., "On the progress of sanitation, preventative as compared with curative science," was taken as read.

THE fund for the memorial to Professor Rolleston, amounting to £530, is expected to rise to £800 or £1,000. The subscribers are to meet shortly to settle what form the memorial shall take.

A GRATIFYING mark of esteem was presented last week to Mr. J. Blandford, on his leaving the neighbourhood of Coxhoe, near Stockton. The testimonial consisted of a massive silver centrepiece, a clock, and side ornaments, on which were inscribed "Presented to Joseph Whitfield Blandford, M.B.C.S., L.R.C.P., &c., by his friends and patients of Coxhoe and neighbourhood, as a token of their high appreciation of his aimable qualities as a personal friend, and as a valued medical adviser."

WEDNESDAY, OCTOBER 19, 1881.

VERY SPECIAL PLEADING.

It is ever an ungracious task to quarrel with those who are the recognised leaders of the profession, and particularly is this so when the cause of complaint is contained in matter ostensibly addressed for their benefit to younger members of the medical societies which flourish in connection with the various hospitals of this country. We cannot, however, refrain from expressing an opinion unfavourable to much that is contained in the address recently delivered before the Student's Society at University College Hospital by Dr. Russell Reynolds, and which has subsequently been widely circulated as the *fiat* of a leader of medicine in relation to specialism. Had Dr. Reynolds, however, confined himself to a review of the question avowedly selected for the subject of his address; had he simply painted the meaning of, and the evils surrounding, specialism, while at the same time duly describing the legitimate practice which universal authority at the present time recognises to be special in the true and proper sense of the word, then none more willingly than we would have commended the performance, and hoped for much good to follow from it. In place of doing this, we regret to say that Dr. Reynolds

availed himself of the opportunity he enjoyed, to utter before a number of young men just entering on the threshold of a medical career, a number of degrading charges against the very body his audience had elected to champion. Whatever may have been his conclusions regarding the integrity of some or many members of the profession, Dr. Reynolds could surely have found some more fitting time to disembarass himself of them, than when delivering what should have had all the elements of encouragement to the young men assembled before him. With the choice of specialism as a subject of address we do not venture to disagree; but when there were so many important ways in which it could have been handled with the greatest advantage to the listening crowd of students—who, by and bye, must decide between general practice and other spheres of professional labour—we do complain that the occasion was rendered in the highest degree barren by the unprofitable way in which it was employed. We trust our knowledge of medical students is correct when it assures us they will be prompt to reject the invitation addressed to them to believe that there are “some who prey upon the sense of shame, and extort money for needless operations and worthless drugs, holding in *terrorem* over their victims the knowledge of facts that have been confided to them, and using that knowledge—which is power—to benefit, not their patients, but themselves.” We, at any rate, will not accept the dictum of even Dr. Reynolds on this point. We do not believe that the medical profession numbers among its members men who are as lost to the honour of their calling, and the claims of humanity, as are those miserable pretenders whom a halting policy of timid inefficiency permits to batten on an income derived from the worst forms of quackery. It may have been formerly, when it was open to almost any thief or knave to dub himself a medical man, that extortion under threat of exposure was one form of practice indulged in by men with a medical qualification; but at the present time, among the men who are legitimate practitioners, and who are necessarily influenced by the higher *morale* imported into the profession, even though they be not immediately actuated by a better feeling, we will not believe there are any considerable number who for a moment neglect the lofty claims of their calling, or are false to the aims that should animate them. A few black sheep there have been; and from time to time they are weeded from the flock, while none are more importunate for their removal than medical men themselves, who are the first to feel outraged by the misdeeds of their underserving *confères*. But this limited meaning will not attach to the sentences in which Dr. Reynolds held such beings up to the scorn of his hearers; the latter will carry with them from his presence the uneasy conviction that many of those they will by and-by number as professional brethren, are such as, were their character fairly exposed, would be meet objects of contempt and loathing. We repeat, this could not have been done at a more inopportune time and place; and, unfortunately, there are other parts of the address that call for almost, if not quite, as strong a protest. The vagaries of “specialism” have again and again served to spur the elo-

quence of orators, and Dr. Reynolds has not succeeded either in adding anything new to what has been often uttered on the point, or in suggesting any remedy for what is universally admitted to be capable of much improvement. Such wholesale condemnation of what is in many cases earnest attempt to perfect the treatment of disease, and is at the worst but an indication of concentration on a particular subject, is likely to do more harm than good in the effect it will produce on young minds not yet attuned to the meaning of many of the distinctions drawn.

On the essential necessity of “specialism,” as we understand it, and as, until Dr. Reynolds undertook to correct us, we considered every educated practitioner understood it, there seems to be an agreement between ourselves and Dr. Reynolds. He admits courses of instruction as given in the hospital and college could not possibly have been made of any use to the general practitioner, unless the teachers had already been taught by their own “special” devotion, or by that of others, to separate branches of study. Moreover, he declares that such special workers are essential to the cause of efficient instruction; and then follows the statement by the remarkable sentence quoted in full below:—“But when I speak of ‘specialism,’ the word carries us into a region quite other than that of helpful work—on to that of miserable retrogression instead of ‘evolution;’ into that of ‘survival *not* of the fittest, but of the charlatan and the quack.” Now, if these phrases mean anything more than oratorical flourish, they indicate that all those men who devote themselves to special work which is in the line of practice instead of in mere teaching, are charlatans and quacks, by reason of their claiming special competence in a branch of medicine rather than pretending to universal excellence in everything. Indeed, this is further explained in a way that prevents any possibility of doubt on the point; and something stronger than a mere impression is conveyed that every practitioner must be prepared to express an opinion on the nature of any and every case that comes to him for treatment. With an appearance of inconsistency, however, most confusing, Dr. Reynolds admits that the limitation which he translates as specialism may be permitted in the case of insanity, his words to that effect being, “The speciality of the physician who directs his attention mainly, or it may be even exclusively, to the charge of the insane, is a most direct advantage to the profession and the public, and this is demonstrated by the fact of its general recognition.” This surely is a refinement of hair splitting in definition to which we are unaccustomed from scientific authorities. Who will dare to draw the lines indicated in Dr. Reynold’s preference for individual specialisations; and where are they to be drawn?

The whole address is disappointing in the extreme, and could not, we venture to think, have been composed by anyone who rightly appreciated the importance and necessity for thorough education on the part of intending consultants. It had been needless to urge the primary importance of complete general instruction of every medical man in the principles of his profession; and equally too ought the time to have gone past in

which any apology is needed for particular study on the part of all who design to pay attention to one aspect of disease rather than another, the study, viz., of a 'special' branch of practice. The men of "great name," against whom Dr. Reynolds covertly sneers, deserve none of the opprobrium heaped upon their performances; and it is curious to note the involuntary admiration compelled by their work, even in him who is self-elected to be their accuser.

Doubtless there are subjects touched on in the address which deserve hearty commendation, but we repeat the time and place for uttering it were ill-chosen. However much we may deprecate the senseless repetition of meaningless congratulation contained in introductory addresses, they do infinitely less damage to the cause of medicine than one such attack as that directed by Dr. Reynolds; and, much as we regret the necessity, we are compelled to register a protest against the address itself, and the circumstances under which it was given to the world.

HOMŒOPATHIC SQUABBLING.

AS might be expected, recent events in the history of homœopathy are being followed by the outbreak in many quarters of controversy and squabbling, not only between those who do, and those who do not, follow the doctrines of Hahnemann, but even among adherents of the school itself, and angry recriminations are being sounded in several directions. In the *Liverpool Daily Post* a series of letters, couched in somewhat heated terms, have lately appeared, one of the writers of which, Dr. John W. Hayward, champions the cause of homœopaths with, at any rate, an outspoken honesty that will command admiration, though it may not carry conviction to the unbelieving. He takes serious exception to a charge brought by an anonymous correspondent to the effect that "homœopaths are, to a man, quite ready to haul down the flag in all serious cases," and he proceeds to claim that it is, in the most dangerous cases, that homœopaths obtain their greatest successes. Moreover, he challenges the assertion that the law of similars is not invariably followed by homœopathic practitioners, and makes a special point of the superiority of the latter's treatment over that in which very little medicine is ordered. It may not, possibly, be known to Dr. Hayward that the *International Hahnemannian Association* specifically admits the truth of the statements he is at pains to refute, and that one of the "principles" of the Association declares "whereas, numbers of professed homœopaths not only violate these tenets (viz., law of similars, totality of symptoms, single remedy, and minimum dose of the dynamised drug), but largely repudiate them." Further, the Association, which is henceforth to include every *real* homœopathic physician, pledges itself to observe to the letter *all* the laws and directions laid down by the founder of their school, and to regard every one not so acting as recreant, and without the pale of the science of medicine. In the face of this, it is disturbing to honest critics who are anxious to know what is, and what is not, essentially characteristic homœopathy, to be incessantly troubled with instances of deviation from the strictly limited path of treatment declared

to be the only legitimate practice; nor can we be blamed if we recognise in the multitudinous bickerings and squabbings as to the meaning of explicitly defined terms, a sign of inherent weakness. It is folly for any advocate of the system to deny what is known to every well-informed student of the recent history of medicine, and no one who is acquainted with what has taken place in regard to homœopathic practice and teachings here, and in America of late, can fail to understand the wholesale defalcations committed by so-called followers of the school.

We must, however, expect for some time a repetition of these unhealthy encounters, and look upon them as evidence of the slow decomposition of an untenable creed.

Notes on Current Topics.

A Warning to Doctors.

THE will of a recently deceased millionaire dust contractor, who died worth upwards of one hundred thousand pounds, contains a clause of special interest to family practitioners, and which runs to the effect that a bequest to testator's medical attendant should vary in value according to the length of time he survived from the date at which the will was executed. In accordance with the terms therein expressed, a sum of £2,000 was to be paid to the doctor provided his patient lived for two years; and a further thousand was to be the reward for a prolongation of three years more. The assumption on which the eccentric condition was made, was, apparently, that it lay within the power of the medical man to apportion the period during which his patient might enjoy the pleasures of existence; and if this was really so, it is difficult to believe that an earnest endeavour should not have been made to dissuade him from executing so improper an instrument. Unfortunately, or fortunately, as the case may be, the doctor failed to benefit by the intention of his client, since the latter lived only for a week after signing the will containing the unusual provision. The occurrence may prove a warning to the profession not to encourage a similar inclination should any of their patients exhibit it; in any way when such a stipulation is made with the knowledge and consent of an attendant, it can redound neither to the credit or wisdom of the latter.

Hydrophobia.

A DEATH from hydrophobia is reported from Penzance in Cornwall, the victim having been bitten by a retriever three months previously to the first onset of the symptoms of fatal disease. The dog, moreover, by which the wound was inflicted, had itself been infected as long as three months before attacking the human patient in this case; a small dog, said to have been suffering from rabies at the time, having communicated the virus to it. The deceased gentleman, Mr. Harvey, a spirit merchant, thought little of the wound he had received, and beyond having it immediately cauterised, paid no attention to the matter. On Monday week, however, he experienced pains and stiffness, the oncoming of which was attributed to cold and approaching pleurisy, treatment in accordance being resorted to. Two days later inability to swallow fluid was apparent, and from that time the case rapidly progressed, the intensest

agony being undergone for some hours, until death at length put a period to the unhappy patient's sufferings. The case is an instructive one, and the particulars of it will be of value in determining some of the points in connection with the existence in a state of latency of the virus of hydrophobia in a person who has once been submitted to its influence.

A Medical Recipient of the Victoria Cross.

HER MAJESTY has graciously signified her intention to confer the Victoria Cross on Surgeon Major Baron Hartley, of the Cape Mounted Rifles, for the conspicuous gallantry he displayed while attending to the wounded during the unsuccessful attack on Moir's Mountain, June 5th, 1879. The special act thus recognised consisted in the removal of Corporal A. Jones, of the Cape Mounted Riflemen, whom Surgeon-Major Hartley carried to a place of safety in face of a constant fire, by which his burden was a second time wounded. Subsequently the gallant officer returned under severe fire of the enemy to dress the wounds of the storming party. Dr. Hartley is eldest son of Dr. Hartley, of St. George's Square, and was educated at St. George's Hospital.

A Remedy for Toothache.

DR. F. P. ATKINSON describes in the *Practitioner*, a novel form of treatment for toothache, to which he was led by Dr. Murrell's results with nitro-glycerine in angina pectoris. Being afflicted with severe toothache, and proceeding on the similarity in effect following the employment of nitro-glycerine and nitrite of amyl, he applied to the aching tooth cotton wool, saturated with Richardson's compound anæsthetic ether, which contains the nitrite. Instant relief ensued, which was maintained for four hours by a pledget of wool previously soaked in laudanum. Dr. Atkinson adds that a one per cent. solution of nitro-glycerine has the same effect in stopping pains as nitrite of amyl; and thus a means of relieving a most distressing complaint is opened up.

Ambulance Stations for Fever Cases.

So decided has been the success attending the experimental establishment of an ambulance station in London for small-pox and fever cases in vehicles specially designed and kept for the purpose, that on Saturday last, at the fortnightly meeting of the Metropolitan Asylums Board, a motion to extend the system to other parts of the metropolis was unanimously adopted. When first mooted it met with the same factious opposition as most reforms have done; local authorities and property-holders vied with each other in one strenuous effort to prevent the idea being carried out; now it has been shown from unimpeachable testimony, that whereas cases of small-pox had occurred frequently in one district previous to the establishment of the ambulance station, not one case had occurred since.

The Irish Pharmaceutical Society.

THE annual meeting of the Society took place on October 3. In his address the President said that during the past year the number of candidates for the Final examination had been less than in previous years, nineteen

only having passed; but the Preliminary showed an increase, forty-three having passed; this looked more hopeful, as it would be expected that these students would hereafter present themselves for the Final examination. The finances did not appear satisfactory. As regarded prosecution, although the Legal Committee had not been idle, yet from some cause its endeavours had not been successful. He considered some cases should be tried in the country, where less was known of the working of the Act than in town. The Treasurer said he had to report that the income had only covered expenses. The total income for the past year, including balance from the previous one, was £421; the annual subscriptions only amounted to sixty-three. He had been unable to invest the £100, for which a resolution had been passed, owing to the present financial state of the Society.

The Bath Hospital.

SOME months ago we drew attention to the fact that a serious want of harmony was apparent at the Royal United Hospital at Bath, and now again public prominence is given to the institution by a leading article in the *Bath Herald* of Saturday last. Complaint is therein made of the rigid exclusiveness exercised in regard to proceedings within the hospital, and a very legitimate protest is raised against the continuance of an archaic regulation by which local members of the profession are refused admission within its walls for the purpose of observing, and, if need be, criticising the treatment of cases in its wards. Another point insisted on, and with justice, is that there are no junior offices on the staff corresponding to the assistant-surgeons of recognised hospitals. Thus a number of young men are debarred from entering on local practice with the advantage a hospital appointment confers, while the charity itself is deprived of valuable services it might most certainly be the better for. The question needs ventilation.

Notification of Infectious Diseases.

THE Medical Officer of Health for Bolton has just issued his fifteen months' report of the health of that town, in which he expresses the opinion that the compulsory notification of infectious disease has given satisfaction, and proved of much value in limiting the spread of contagion. At the same time he had to report that zymotic diseases were very prevalent in the locality during this period, and gave rise to 692 deaths, equal to 24.4 per cent. of the entire mortality, and 4.5 per 1,000 of the population. As compared with the previous year the zymotic death-rate was more than doubled, and showed an average higher than any recorded during the previous ten years. This does not look as if the notification system had done much for the health of the town, though it has been in operation for a longer period than anywhere else. He further states that the reported infectious cases "fairly" represent the number of cases treated, which looks as if a substantial percentage escaped detection altogether, and therefore acted as fertile centres of infection. It is also a fact worthy of note that the Parliamentary representative of the very town where the system works, we are told, so admirably, is the person who has determinedly refused to allow the system to be adopted elsewhere, and who has stopped the Bill in the House of Commons.

Referring to the discussion on the subject in the Social Science Congress, a contemporary says:—"This matter will probably shortly be legislated upon, but the proposal to make every practitioner a sanitary informer is diametrically opposed to the confidential relations that ought to exist between doctor and patient. The information is for the well-being of the community, and the individual members of the community are those on whom the responsibility of affording it naturally rests."

This is exactly what we have insisted upon. We hold that the custody of the patient or owner of the infected house, and no one else, should be responsible for notification. The misfortune is his—the danger to the neighbours is of his making, he is the person bound to apply the needful remedies and precautions, and, both in justice and in common sense he should be the person to report the disease. It suits the Dublin Corporation and the few neck-or-nothing sanitarians who have prompted Mr. Hastings and Mr. Gray to assert that there can be no efficient notification by any one save the physician. In support of this theory they offer no atom of evidence, and they carefully ignore the success of the Greenock system of notification by the householder. In truth there would not be the least difficulty in an efficient sanitary authority, if such existed in Ireland, enforcing a similar system in that country. A little vigilance as to causes of registered deaths, and as to cemetery certificates, a few vigorous prosecutions, and a few pounds spent in advertising the public of their duty, and their legal liabilities for non-performance of it, would effect all that is needed. But vigilance is the last quality which we should hope to find in the Dublin Corporation or any other Irish sanitary authority, and it is to save themselves trouble and expenditure that it is now sought to convert Irish physicians into infectious detectives.

The method adopted to get the Edinburgh Bill through the House of Commons will not, we can assure the notificationists, succeed *quoad* Ireland. One of them, speaking to the Social Science Congress, candidly told them that the Health Officer of Edinburgh had lulled the doctors into lethargy by refraining from going to London to press the Bill, and by making no noise about it until the measure had been passed, after which the protests and remonstrances of the doctors were laughed at. This, we believe, is the example which the Parliamentary Bills Committee of the British Medical Association desire to imitate, and, if the members of the Association do not awake to the danger in which they are placed, we suspect they will, before the lapse of another session, learn that they have placed a false confidence in their *soi-disant* protectors.

Heroes of Majuba Hill.

FROM details kindly furnished by Surgeon-General Longmore, which will be found in another column, the fact now appears that the wounds received by Corporal Farmer and Private Sealey, of the Army Hospital Corps, while bravely and manfully doing their duty at Majuba Hill, have permanently incapacitated them, not only for military service, but, to a great extent, for earning their living in the occupations of civil life. It is seldom, indeed, that dramatic incidents are presented in clinical records so vividly, and yet so touchingly, as are those in the reports

alluded to. And what do they represent? Surgeon Landon, with his two subordinates, in the turmoil of battle, themselves cool and collected, fulfilling their high mission of giving help to others struck down; continuing at their high post of honour even when, as is stated, "the troops were retreating past the spot." The surgeon, while attending to a wounded man, is himself struck by a bullet. He at once recognises that his injury is mortal. His lower limbs paralysed, he begs that his trunk may be raised and supported, that thus while power remains, he may perform the only operation which can give relief, not to his own sufferings, but to those of the wounded man upon whom at the time he was attending. Corporal Farmer holds up an extemporised flag as signal that wounded men lay on the spot; the arm, by which it was supported, is disabled by a bullet; with the other hand he again raises the emblem of truce, but instantly that arm, too, is pierced. Private Sealey, while half kneeling over a wounded soldier, is struck by a bullet, "which passed through him near the left shoulder." Not realising for a moment the fact that he had been shot, he "went on bandaging the patient." While so engaged, is struck by a second bullet in nearly a corresponding place on the right side. His arm now dropped useless by his side.

Surgeon Landon's memory lives as that of a man who died at the post of duty, manifesting an example of professional heroism, than which it is difficult to imagine one more perfect. Of the two survivors, one has been decorated with the Victoria Cross. But what about their pensions and rewards for bravery, by means of which their bodily requirements are, for the future, to be met? It is well and appropriate that in cases such as those of Corporal Farmer and Private Sealey, an expression of admiration of gallant and praiseworthy conduct should take the form of a presentation of money. In this sense we cordially approve of the scheme proposed. Considering, however, the exceptional nature of the circumstances under which very remarkable staunchness and bravery were exhibited, surely the case of these two soldiers is one most suitable for special, and, it may be, exceptional consideration by the War Office.

Indian Medical Items.

THE Governor-General of India has made the following appointments to his personal staff, viz. :—To be Honorary Surgeons—Surgeons-General W. R. Cornish, C.I.E., and A. J. Payne, Deputy Surgeon-General W. J. Moore, Brigadier Surgeon J. A. Marston, Surgeon-Majors G. Farrell, T. E. Charles, M.D., R. W. Cunningham, M.D., and C. A. Atkins, and Surgeon A. H. Roe, all of the Army or Indian Medical Services.

The health of the troops at Quetta has improved. Cold weather has fairly set in there.

Umritsur is suffering from a severe epidemic of fever. The total deaths in that city for eleven days ending October 1st were 2,265, of which number 1,138 were children. The pestilence is believed to be due to the late abnormally heavy rainfall.

The total number of deaths from cholera in Lahore and Meean Meer during June, July, and August amounted to nearly 70 Europeans and upwards of 1,200 natives. It is

satisfactory to learn that the disease is now abating generally throughout the Punjab.

Throughout the Bombay Presidency there was a decrease in the number of deaths from cholera during last week reported, as compared with the previous week and the weekly returns for some two months past; but the disease still continues to cause numerous deaths in the Khandesh, Ahmednagar, and Sholapur districts.

Predisposition to Hysteria.

UNDER this title M. Briquet read recently a paper in the French Academy, of which the following are the conclusions:—

The predisposition to hysteria arising from menstrual influences presents some phenomena peculiar to itself and very remarkable. In forty-two cases of hysteria developed under the influence of menstrual irregularity, he found one in which the menses reappeared at the end of two years, and then all the hysterical symptoms completely disappeared, and health was re-established. One similar case of cure after a year and a-half, one after eleven months, two after ten months, one after eight months, two after seven months, two after six months, two after five months, and one after four months. Thus, out of forty-two cases, thirty-one were relieved of the hysteria after reappearance of the menses.

Professional Candour.

THE Philadelphia *Medical Reporter* has a candid friend, to whom the Editor complained of certain unflattering observations made by an instrument maker respecting the commercial morality of the profession. Instead of the indignant sympathy which was expected, the editor received an abject confession of all the crimes charged by the instrument maker, and he prints the following oburgation as a rare specimen of professional candour:—

"Your instrument maker was entirely right. The whole practice of medicine is based, to a certain extent, on deception, and these base arts poison a doctor's mind and destroy his sense of honesty.

"You are called to a patient, in nine cases out of ten you have to deceive him or the family, or both. You represent the disease is more serious than it is, in order to get more credit for its cure; or you pretend there is no danger, lest you create alarm, when you yourself are quite uneasy about it.

"Again, you are constantly asked by your patients and their friends numbers of questions which you cannot correctly reply to, because you do not and cannot know the answers. But you must not confess ignorance, nor even doubt, or else you are reported as a dull fellow at the corner grocery and the sewing circle. No, you answer positively and promptly, though you are lying, and you know it.

"Your competitors pretend to knowledge which they do not have; you must do the same, or else you lose business, through unfavourable comparisons.

"You are called in to help some friendly doctor out of a scrape. You do it through a series of deliberate deceptions practised upon the patient and the family.

"A mother insists you must prescribe for her children when it is clear they need no medicine. You write, for a placebo, mint water, coloured and sweetened, and you give

minute directions about administering it. You do your duty by your patient, but you have acted a lie, and your moral nature suffers for it.

"You cannot be expected, when you are in active, practice, to know every new-fangled instrument and remedy that comes out; but to hold your own you are often obliged to pretend to do so, or else run the risk of being crowded out by some new-fledged graduate.

"If physicians, in short, become habitual liars, I don't see how they can be expected to be anything else."

Whether this is a fair representation of the medical men of Philadelphia we must leave the Editor to say. Whether it has in it any *soupcion* of truth when applied to our confraternity at this side of the Atlantic we must remit to the judgment of our readers. At any rate, it is plain, emphatic, and uncompromising.

Professor Schutzenberger.

THIS gentleman, the greatest medical celebrity of Strasburg, has just died in consequence of an attack of pneumonia. Born in 1809, and appointed Professor of Clinical Medicine in 1845, Dr. Schutzenberger, although the subject of a painful disease, performed all the duties of his chair during thirty-five years, and became the centre of all medical activity at Strasburg, promoting every modern investigation, and raising the clinic of that Faculty into the first place in France. After the German occupation he struggled for a long time in the endeavour to still maintain a French medical school in the city with which he had been so long identified. His work on "Fermentation" is well known in this country.

Relief of Pains in Locomotor Ataxy.

FOR the relief of these, Prof. Vulpian recommends that compresses of many folds, after having been immersed in water and wrung out, should be moistened with a teaspoonful of chloroform and then applied to the painful parts and covered with oiled silk. They produce both a revulsive and anæsthetic effect, which relieves the pain. We may employ them also, or have recourse to chloroform ointment, in the case of neuralgia of nerves situated superficially, and in muscular rheumatism. If the cold of evaporation is sought to be obtained for local anaesthesia, ether should be substituted for chloroform.

The Mecca Pilgrimage as a Cholera Nidus.

THE Turkish Sanitary Commission has decided that, in consequence of the outbreak of cholera at Mecca, ships having on board pilgrims for the Mohammedan holy places shall not be cleared for the Red Sea ports. A Russian steamer from Odessa, arriving recently in the Golden Horn, was obliged to land a number of pilgrims before proceeding on her voyage.

Nerve Stretching in Tetanus.

MR. WHEELER stretched the median nerve of a female child, in the City of Dublin Hospital on Sunday last, who was suffering from tetanus caused by an injury to the middle finger of her right hand. Since the operation the abdominal muscles have relaxed, and the spasms have not been so frequent. The result is looked for with interest, being, we believe, the first time the operation has been performed for tetanus in Dublin.

The Annual Election at the Irish College of Physicians.

YESTERDAY, being St. Luke's Day, was the chartered election day of the King and Queen's College of Physicians in Ireland, and the occasion possessed unusual interest in consequence of the appointment of a "King's" Professor of Materia Medica fixed for that day, *vice* Dr. Aquilla Smith resigned. This is one of the chairs connected with the School of Physic of the University of Dublin, and the professorship has heretofore been usually combined with the clinical physiciancy of Sir Patrick Dunn's Hospital, though we believe there is no legal necessity for such connection. On this occasion the candidates are—Dr. Walter Smith, son of the outgoing professor, and Physician to the Adelaide Hospital, and Dr. G. F. Duffey, Physician to Mercer's Hospital and Lecturer on Materia Medica in the Carmichael School. For the Censorship of the College there was also a contest, three Fellows—Dr. J. W. Moore, Dr. C. F. Nixon, and Dr. Quinlan, having offered themselves as claimants for two vacancies. There were no applicants for the Fellowship of the College which, our readers will remember, is simply a co-option of a favoured applicant by the ballot vote of the existing Fellows, but the name of Professor Helmholtz, on whom the Irish College of Surgeons recently conferred its honorary Fellowship, was proposed for a similar honour on the part of the College of Physicians. Dr. George Johnston was to be elected President for another year, he having consented to accept the office in view of the present inability of Dr. Hayden to assume the presidency, to which he would certainly have been chosen if his health permitted.

As these elections were to take place on yesterday (Tuesday) evening, it is impossible for us to inform our readers of the result until our next issue.

Dr. Hayden, of Dublin.

WE are much gratified to be able to state that the almost unhopd-for change for the better in the very alarming condition of Dr. Hayden has been maintained, and, during the week, very satisfactory progress towards convalescence has been made. There is now every hope of Dr. Hayden's complete restoration to health.

The Royal Irish University.

THE matriculation examination of this University, respecting which we gave full particulars last week, will be held on the 6th of December, and Saturday last, the 15th, was the last day for sending in applications to be examined. It is stated that more than 100 persons have asked for forms of entry. No student who has already studied in another university can compete for prizes in a lower grade than that which he has attained.

Homœopathy and the British Medical Association.

THE *Lancet* states that at the Committee of Council of the British Medical Association, held on Wednesday last, a letter was read from the President of one of the branches of the Association, stating that a homœopathic practitioner in his neighbourhood had been admitted a member of the Association, and that unless his name was removed from

the list of members, he, the writer, would feel compelled to resign his membership. An earnest discussion ensued, in which the opinion was generally expressed that it was distinctly contrary to the laws of the Association to admit homœopaths as members, and opposed to the opinion and wishes of the Committee of Council. As, however, the expulsion of any of the members on account of homœopathic practice would give those individuals both notoriety and a quasi-grievance, it was considered best not to adopt the step suggested by the writer of the letter. A resolution expressing these opinions, moved by Dr. Husband, was carried; an amendment, moved by Mr. C. Macnamara, to erase the said individual's name receiving only very small support. This episode would seem to justify the protest which journals unconnected with the Association felt it necessary to record against the Bristow-Hutchinson tenets. The old saw that "there is no smoke without fire" is applicable. The Council of the Association may not approve of fraternisation with homœopaths, but, manifestly, there are many within its membership whose mouths water for the flesh-pots of homœopathic consultations.

DUBLIN Hospital Sunday will be held this year on November 13th.

It is stated officially that the nomination of Sir James Paget for the office of Rector of the Aberdeen University, is free from political bias.

A PURSE, containing 100 guineas, has been presented to Dr. S. Lewis, of Liverpool, as a mark of respect and in recognition of the value of Dr. Lewis's professional services, chiefly in connection with the Jewish schools in the city.

THE seventeenth anniversary festival of the Guild of St. Luke was held in St. Paul's Cathedral yesterday evening; the offertory being devoted to the funds of the guild. Seats under the Dome were reserved specially for the medical profession, of whom there was a fair attendance.

THE Treasurer of the Children's Hospital, Pendlebury, has received towards the funds of the charity £10,000 under the will of the late Mr. Wrigley. Colonel A. R. Naghten, late of Blightmont, has bequeathed £500 to the South Hants Infirmary.

THE dinner given by the London and District Medical Staff of the St. John Ambulance Association to Major F. Duncan, R.A., will be held at Limmer's Hotel, Conduit street, on Wednesday next, at 7 o'clock. Dr. Sieveking will preside. Gentlemen who have acted as Instructors to Ambulance classes at the various centres wishing to be present can obtain all necessary information from the hon. secretary, Mr. J. Cantlie, F.R.C.S.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population, were—Bristol 12, Norwich 13, Oldham 16, Brighton 16, Plymouth 16, Birmingham 17, Leicester 17, Sunderland 17, Nottingham 17, Bradford 17, Portsmouth

17, Edinburgh 17, Dublin 18, Sheffield 18, London 18, Leeds 18, Wolverhampton 19, Salford 20, Manchester 21, Hull 21, Liverpool 22, Glasgow 22, and Newcastle-on-Tyne 24.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 25, Bombay 26, Madras 35, Paris 23, Geneva 17, Brussels 20, Amsterdam 20, Rotterdam 19, The Hague 21, Copenhagen 20, Stockholm 18, Christiana 13, St. Petersburg 41, Berlin 22, Hamburg 20, Dresden 21, Breslau 26, Munich 27, Vienna 24, Prague 23, Buda-Pesth 30, Rome 29, Turin 22, Alexandria 43, Philadelphia 20, and Baltimore 26. No returns have been received from New York, Brooklyn, Venice, Lisbon, and Naples.

FROM diseases of the symotic class in the large towns last week scarlet fever showed the largest proportional fatality in Hull, Nottingham, Brighton and Leicester; during the past fourteen weeks no fewer than 253 fatal cases of this disease have been recorded in Hull, the 28 last week corresponding with the number in the previous week. The 32 deaths from diphtheria included 12 in London, 8 in Portsmouth, 5 in Glasgow, 4 in Edinburgh, and 3 in Birmingham. Small-pox caused 15 deaths in London and its outer ring of suburban districts, one in Salford, and one in Oldham; no fatal case of this disease was recorded in any of the other large towns.

Scotland.

(FROM OUR NORTHERN CORRESPONDENTS.)

ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH.—The directors of this hospital have appointed Dr. D. J. Hamilton pathologist to the hospital, in room of the late Professor Sanders. They have also appointed Mr. R. MacKenzie Johnston, M.B., C.M., L.R.C.S.Ed., to be resident physician, in room of Dr. Hodsdon, whose term of office has expired.

GLASGOW.—COMBE LECTURES.—The first of the Combe Trust Health Lectures, in connection with the Glasgow United Young Men's Christian Association, was delivered on the 10th inst., by Professor McKendrick. He was accompanied to the platform by several distinguished philanthropists. The lecture was on "Bodily Waste and Repair," and was repeated in the National Halls, South Side, on the following evening. A series of such lectures by medical gentlemen in Glasgow has been arranged. The subjects in most cases are unobjectionable. We fear we cannot say the same for the lecture which is to be delivered exclusively to women. We doubt much the elevating tendency of a promiscuous meeting of prurient women to listen to prurient details regarding their sexual apparatus; and would have preferred that the lecturer should have selected some other subject, which would be equally efficacious as an advertising medium, and less objectionable.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday the 8th inst., were at the rate of 22 per 1,000 per annum, against 18 in the previous week,

and 22, 19, and 22, in the corresponding periods of 1880, 1879, and 1878.

FEVER IN DUNDEE.—The efforts of the sanitary authorities to stamp out fever in Dundee, are being attended with success. There are now no cases of typhoid, and no cases of typhus have been reported during the past fortnight. Scarlatina still prevails, but it is diminishing in extent and virulence.

THE ROYAL COLLEGE OF SURGEONS, EDINBURGH.—At the meeting of the College to-day (Wednesday) the election of the President, Council, Examiners, and other officers will take place. The name of Professor Turner has been mentioned among others for the Presidency, but we believe that he has declined for the present the proposed honour. Professor Turner is a member of the Royal Commission on the Medical Acts, and his duties on that Commission and as President of the College are so diametrically opposite that he would find it impossible to be just to both. The Commission should, or rather ought to be, on the side of progress, whereas the College is on the side of stagnation, to which it clings as firmly as paludal miasm to a marsh. After the election of the President, who is proposed by the Council, and of course will be duly approved by the Fellows, the meeting will probably relapse into its normal condition. Fellows will be invited to elect the examiners, and to this request the former examiners will accede by electing themselves. Dr. Cathcart and Mr. Hamilton will be licensed, the one to teach anatomy, the other pathology, and after the election of new Fellows the meeting will be dissolved amid mutual congratulations. By the bye, we see that a Fellow proposed for election at a subsequent meeting only gained his license this year. It would be interesting to know on what grounds his claim to the Fellowship distinction. At a late meeting it was stated that the "Fellowship distinction" was conferred as a reward for merit and distinguished services; a nestling with its first feathers scarcely outside the skin can hardly claim much distinguished services to the parent nest.

STUDENTS' TEXT BOOKS.—It is the custom with most lecturers and teachers to point out to the students attending their classes the text books with which it is advisable they should make themselves acquainted. Some teachers err on the side of offering too many books, the result being a considerable expenditure of money on the part of parents, and a great source of gain to the second-hand booksellers, who are only too ready to pay a trifle for an uncut and unread book. But not to recommend a suitable text book is as grave an error on the other side, for all that an examiner can fairly expect of a student in a subject like pathology or indeed, any other, is, that he shall show a competent knowledge of some good text book which should be selected for him by his teacher. We learn, however, that the Professor of Pathology in the University of Edinburgh finds it impossible to recommend any English work on the subject to his class. We referred last week to the abuses which result from the practice of allowing teachers to examine their own pupils, and in this case it is not difficult to see what the result will be. If there is no book in the English language on Pathology suitable as a text book for the student his only alternative is to take out the Professor's class and take good notes in which he will be doubtless required to show some knowledge. The absence of a good text book may fill a class room, but it may also prove the last straw, and break the back of a system which is becoming perfectly vicious.

A NEW LECTURER ON PATHOLOGY AND ON ANATOMY IN THE MEDICAL SCHOOL, EDINBURGH.—Mr. D. J. Hamilton will

commence a course of lectures on Pathology this session, and, owing to his immense popularity among the students, will doubtless obtain a fair class. Mr. Cathcart, an old demonstrator at the University, will also lecture on Anatomy. Mr. Cathcart is a man of considerable culture, and we believe is very popular with the students.

THE EDINBURGH HEALTH SOCIETY.—This Society has been established to promote the observance of the laws of health in Edinburgh and the neighbourhood. A public meeting is to be held on Friday, Oct. 21st, the Earl of Rosebery in the chair. An imposing syllabus of lectures has been issued, which, if the novelty has not worn off, it is hoped will be attended with a like success to that of last year. The origin of the society is entirely due to the energy and public spirit of Mrs. Trayner, the wife of a well known Edinburgh advocate.

Literature.

A TREATISE ON DISEASES OF THE JOINTS. (a)

CHAPTER I. is headed Physiological Anatomy, and treats of the classification of joints, and of the elements of which bone is composed. "The cells of the bone are contained in the lacunæ, the cell walls lines the spaces, and the nuclei may be seen in them" (p. 3).

At page 11 the author, in describing cartilage, says "cartilage is a tough elastic material, of a semi-transparent bluish appearance, and easily cut with a knife. This entire chapter is of so very primitive a description, that we regret the writer did not omit it altogether, and refer to the various well-known students' class-books, describing the subjects which he attempts to treat under the head of physiological anatomy. In Chapter II. he gives an account of the morbid anatomy and pathology of synovitis, and clearly epitomises the appearances presented by the different joints. He says (p. 48), the deltoid looks fuller and broader than the norm (*sic*), or than the other side; this is best seen by seating the patient in a low seat, and looking down on the shoulders from above the humero-pectoral groove, is, at its upper part, nearly obliterated, or rendered indistinct; the depression at the back, below the acromion, is lost; the axilla appears to the finger shallower than usual. The reader is warned not to mistake inflammation of the sub-deltoid bursa for synovitis of the shoulder; this disease simply envelopes the outer parts, and broadens the deltoid without giving rise to the other signs mentioned. In like concise manner the elbow, wrist, hip and ankle joints, are disposed of. There is an accurate description given of fibrinous synovitis (p. 512), but the only joint the author has seen attacked has been the knee, and, probably, twice the hip; we, have, however, seen both these joints, and the ankle also, attacked with every symptom of well-marked dry synovitis. In the treatment of synovitis (p. 53), the author endorses and adopts the practice prescribed in all recent class-books of any worth. We have not, however, experienced the same success which he lays claim to in evacuating distended joints with the aspirator, and would caution the reader of p. 58 not to be too sanguine that the aspirator will, "almost at once," subdue the inflammation. We have known the very contrary to occur. In the treatment of synovitis, "*sicca*, p. 64," we have, in addition to the remedies recommended, seen great benefit, and complete relief from pain, result from the application of the cautery.

At page 70 the pathological changes which occur in suppurative synovitis, are accurately described, and M. Richez's observations are quoted, and at p. 76 the false position of joints and sub-luxations are considered. At p. 77 the symptoms of suppurative synovitis is fairly described, and the general and local treatment afterwards discussed; we can fully endorse all that the author says respecting the advantage of free incision in such cases, and of the advantages of antiseptic surgery, if by that he means absolute rest, drainage,

and cleanliness. In Chapter IV., inflammations other than those produced by local causes, are treated under the headings of "pyæmic joint disease," and that from the absorption of morbid matter. The difference between septicæmia and pyæmia, the author regards as only one of degree, and the cause of non-appearance of abscess in the former, merely a want of time for their formation. For the treatment of pyæmia the writer recommends the administration of quinine, and the sulpho-carbolates, and that the wound, if it be large enough, should be opened and washed out with a three or five per cent. solution of carbolic acid. If the source of the disease be a mere puncture, a probe should be passed along its track, and the opening enlarged until it can be thoroughly exposed to the action of the antiseptic lotion, p. 122. We may adopt the further measure of opening up the wound, and thoroughly cleansing it when symptoms of blood poisoning appear. We have no objection to the solution of carbolic acid alluded to, but have seen excellent results from thorough cleansing with a solution of chloride of zinc, and such agents, and without the employment of carbolic acid. In the employment of carbolic acid so extensively, our readers should keep before them the danger of poisoning by absorption. The following chapters on strumous synovitis, as well as rheumatic and gouty forms of the affection, well repay perusal, and the same may be, to a certain extent, said of the description, "pp. 267-408," of moveable bodies, and of arthritis deformans, although we have not been able to discover anything original, or that we have not seen before. In the XIV. Chapter the author treats of that most difficult subject, disease of the hip-joint. An articulation which, as he justly observes, is so important to the economy, but, at the same time, so deeply situated, that unlike the knee, or other joints, it is impossible by the finger to ascertain its condition as regards swelling and other conditions. He carefully describes the early symptoms of this formidable affection and foremost pain felt in the knee, and of this he gives the explanation of Bell, Brodie, Coulson, Richez, Stromeyer, and of Walther.

In confirmation of his own view that the pain is caused by periosteal irritation of the branches of the crural nerve, he gives a typical case of Sir Edward Holme, where an exactly similar pain was caused by a femoral aneurism, and was at once relieved by reduction of the aneurismal tumour, consequent on deligation of the artery. Death having ensued in consequence of venous inflammation, it was found that the aneurismal swelling terminated exactly at the seat of pain, and that there was stretched upon it a mesh of small twigs of the crural nerve. This case appears to us to afford distinct pathological proof of the accuracy of the author's ideas in this respect. The subject of shortening real and apparent is next discussed, and the author's views illustrated by neat woodcuts, and if there be little that is novel in his explanations, the subject is clearly and correctly set forth, and the same may be said of the question of coxalgic abscess. The author now puts forth, and suggests that phimosis is a leading cause of hip disease in male infants, and vaginal irritation in females, and rests his views upon tabulated statistics; it appears to us, however, that this point is one requiring further inquiry. He describes *seriatim* the mode of distinguishing hip-disease from various affections simulating it by careful gentle rotation of the thigh, while the patient's attention is otherwise engaged; in fact, he describes the plan recommended by Mr. Butcher, and also by the late Mr. O'Farrall, for the comparative diagnosis of hip-disease for periostitis of the upper third of the femur, which, in many respects, so closely resemble it; the chapter concludes with various methods of treatment, which are all well, and clearly enumerated. The XV. Chapter treats of sacro-iliac disease, of which the author describes two forms, one purely vertebral, and the other occurring in the joint between the sacrum and the os innominatum, and for this rather obscure affection, he gives the symptoms and means of differential diagnosis.

The next chapter treats of synovial and thecal enlargements, foremost among which the author places the well known "housemaid's knee," both in the early stage curable by blistering, or even by iodine and pressure; and in its more advanced stages, when the walls of the bursa have become thickened by successive laminated deposits so as to reduce, and even abolish the central cavity; this form of tumour must be dissected out. We cannot agree with the writer that "all danger from suppuration will be avoided by performing the operation antiseptically, although we quite admit that antiseptic precautions will lessen the chance of suppuration, provided the surgeon does not irri-

(a) "A Treatise on Diseases of the Joints." By Richard Barwell, F.R.C.S., Senior Surgeon and Lecturer in Surgery, Charing Cross Hospital. Second Edition, Royal 8vo, pp. 690. London: Macmillan and Co. 1881.

tate the wound inflicted by a hurtful and irritating spray of carbolic acid. The author describes the ganglia in connection with the tendons of the hand, and gives the well-known method of determining whether they communicate with the joints or not, by watching whether they empty on pressure and then refill. He properly stigmatises as barbarous the custom, now more honoured in the breach than in the observance, of curing them by a sharp blow of a book, or other hard object, and recommends evacuation by subcutaneous incision. He describes a number of the bursal enlargements of the arms and legs. There is an instructive chapter on hysterical simulation of diseases of the joints, but we feel rather inclined to take exception to the statement of our author that this form of hysteria is more common in unmarried women of over forty-five than under twenty-eight; in our experience the period extending from puberty up to thirty or thirty-five is that most subject to the affection in question. The diagnosis and treatment is given at length, but there is nothing novel in them, and some points not sufficiently dwelt upon. The next chapter treats of the restoration of crippled joints, and is by far the best portion of the whole work. All the ordinary forms of crippling of the various joints are set forth at length, as are also the appropriate methods of relieving each by extension and anaesthetics, or by other means, including subcutaneous section of the bones, as practised by the American surgeon, Rhœa Barton, in 1826, and subsequently by numerous operators on both sides of the Atlantic. This department of surgery has been too much invaded by metropolitan bone-setters, and we are glad to see it now treated in so practical and scientific a spirit. A short but interesting chapter is given on genu varum and valgum, and the operations incidental thereto, but it appears to us that the author has not realised the liability to relapse after apparently successful operations.

The whole work concludes with a careful and exhaustive summary of the precise state of our knowledge on that most important branch of surgery—the resection of joints. The author starts from the classical case of resection of the knee by Paake, of Liverpool, in 1781, who, it appears, was anticipated nearly twenty years by another British surgeon, and goes, *seriatim*, through the resection of various joints, pointing out their diseases and circumstances in which they are suitable, and the treatment and precautions necessary in each instance. It would be manifestly impossible in the limits of a review to criticise the details of a subject so vast, and one upon which most eminent surgeons are in many respects divided in opinion, without committing ourselves to all the author's views. We feel bound to say that the summary is a good and practical one, and will command the approval of the educated surgeon.

Upon the whole, we consider the present volume a useful contribution to practical surgery. In some points it is wanting, and would be considered commonplace; it is, however, the outcome of a practical clinical writer, and some will arise from its perusal with profit.

Correspondence.

NOTIFICATION OF INFECTIOUS DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I very much regret that I was unable to attend at the meeting of the Social Science Congress to take part in the discussion on the Notification of Diseases Bill.

I was particularly anxious, as having made it my business since the debate on the subject in the Irish Medical Association in June, to collect the opinions of my friends in the country on the subject. I could have stated that I had not spoken to one who wished for the compulsory clause, or to one who was not opposed to it.

I should also have borne witness to the fact that not one put forward his own interest in the matter; as a reason for opposing it, all at once said it would be unfair to their patients.

I will not lose time by defending the profession against a

charge of being unwilling to sacrifice their own interests to the good of the public. The history of the profession answers this charge, and I may repeat what Lord Derby so well expressed a few days since at University College—that there is no profession which make such sacrifices to the public well as the medical profession. Nor can they be charged as being backward as promoters of sanitary measures, who have, through so long a period, being the unpaid advisers of the public in season and out of season, in all measures tending to the promotion of health.

I must, sir, at once deal with a point of practical importance. Dr. Moore holds out the bribe of a pound fee for each notice served. How could we expect a fee of such an amount from a public that not long ago thought one shilling sufficient remuneration for each case of vaccination, and which daily wrangles over every claim made for payment, when the medical man has to attend cases of vaccination prosecution! How can we expect the public to pay even two shillings and sixpence for each notice when they compel medical registrars to write 160 words for one shilling, and give copies of registration for sixpence? Let no medical man think that he will make money by this compulsory notification, except, perhaps, during the pressure of some urgent epidemic, when he might be more profitably employed. When the first registration bill was introduced, the Irish Medical Association vigorously opposed the compulsory notice of death until the penal clause was withdrawn, and I trust we will be firm in now resisting a similar indignity.

The profession owe Dr. Jacob deep thanks for his vigilant care to prevent this bill from being forced on us, at all events, without our knowing what was being done; and it, therefore, becomes all who think with him to promptly give him evidence of the wish to support him. If every medical man, who is unwilling to yield to the wishes of over-fussy sanitarians, would send him a post-card, expressing on it their dislike, it would strengthen his hands very much, and give them very little trouble.

Dr. Cameron, in his omniscience (and for his varied accomplishments I have great respect), thought fit to tell Dr. Jacob that, though respectable in his own department, he was ignorant of sanitary matters; but we know that when a man of Dr. Jacob's talents and energy takes up a subject of this kind, he is as likely to attain sufficient knowledge of it; and we country doctors place our interests in his hands with every trust that they will be carefully looked after.

I am, Sir, yours, &c.,

JAMES MARTIN, F.R.C.S.

Portlaw, Oct. 8th, 1881.

MR. BURDETT ON HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read in your columns (Oct. 12th), a paper brought before the Social Science Congress by Mr. H. Burdett, on Hospitals, with the utmost astonishment, and hasten to contradict a portion of it most emphatically.

As one of the Grand Committee of St. Thomas's Hospital, I beg to inform Mr. Burdett, and your readers, that there is no friction between the treasurer and the staff. That everything works there in the most amicable manner. The treasurer takes the staff into his confidence, and is guided by them on all matters connected with the medical welfare of the hospitals.

The internal management is carried on with the assistance of a house-committee of six, two of which are appointed by the staff, and the best interests of the hospital are confided to their care, no alteration being initiated in any way in the internal management of the hospital, which has not first met with the approval of the house-committee, or has been first recommended by them. For some years past the

annual dinner of the school has been held in the Hall of St. Thomas's Hospital. The dinner has been attended by the treasurer and some of the governors, and if Mr. Burdett had been present, either at the last, or the preceding dinner when I had the honour to preside, he would have recognised the popularity of the treasurer in the applause with which his name was greeted by the students and the staff when his health was proposed by the Chairman. I hope Mr. Burdett will hasten to correct the wrong impressions which his paper is calculated to produce.

I am, Sir, yours, &c.,

ALFRED CARPENTER, M.D.

Croydon, Oct. 15th, 1881.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—In speaking of the hospital distribution of the metropolis, in his late interesting communication in your last issue, Mr. Burdett makes one omission, which I trust you will kindly allow me to supply. This is, that the north of London, with one million inhabitants, possesses but one hospital, viz., the Great Northern, with 38 beds. Until lately this statement was correct, but about three years ago the institution, known as the North West London Hospital, was started to supply the pressing wants of the not very wealthy and crowded districts of Hampstead, Kentish and Camden Towns.

This hospital contains twenty-six beds, which are always full, and is now furnished with all modern improvements and new specialities for the successful treatment of disease. The out-patients number daily about 80, from each of whom, unless when recommended by a subscriber's letter, or when urgency presses, a small payment of sixpence or a shilling is demanded. This plan preserves the independence of the sick, and helps the funds of the hospital. The medical men, however, here, as elsewhere, give their time gratis.

I remain, Sir,

Your obedient servant,

A PHYSICIAN TO THE HOSPITAL.

Oct. 16th, 1881.

SHAMPOOING IN LIVER ENGORGEMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—In your last issue you draw attention to the treatment by Dr. Durand Fardel, of hepatic engorgement of an intermittent form, by the continuous use of what he calls the *massage* or shampooing, and which is really a process of kneading, or a combination of gradually applied skilful friction. Now Sir, there is nothing new in this, as you will see by a perusal of the accompanying pamphlet, "The Burmese, what do they know of medicine"? which I published in 1875. After drawing attention to the far too numerous branches into which the profession in Burmah, as with ourselves, is cut up, the following passage occurs:—"And lastly there are the Aneiktee (from Neiktee, to press), or shampoo as it is called in India. This pressure or shampooing is quite an institution in Burmah, and deserves a word of notice, as it is practised here much more scientifically, if I may use the expression, than in India. The different tendons, nerves, and *internal viscera* being stimulated into functional activity. It is the first curative process invariably had recourse to, and in addition to other treatment is continued almost without cessation to the termination of the disease. For instance, if a man feel quite exhausted and send for a doctor, two or three people would be set to shampoo him; if he has a pain in his head or is distressed in mind, the back and sides are shampooed, and if a woman is being delivered, even then she is shampooed. I have heard of a girl suffering from liver disease being cured after twelve hours continuous shampooing by an adept who received 200 Rupees for his fee. This practice was introduced from Manipur."

Since the above was written, I have had opportunities of testing for myself, on several occasions before leaving Burmah the value of this mode of procedure. It must not be applied without some caution. It should never be used in acute congestion, in perhepatitis, or in commencing inflammation. In such cases I have however, seen it practised by the native physicians, and with grave results, though often followed for a short time by a sensation of ease and relief, thus enabling the doctor, by attributing

any aggravation of the disease to its original severity rather than to the unsuitability of the attempted cure, to come off, not only with some *eclat* in the eyes of his patients, but of an ignorant man, with complete satisfaction to himself.

Under the conditions referred to by M. Durand Fardel it can do no harm, and is often undoubtedly attended with very good results. In a doubtful case the temperature will give valuable indications, for in my opinion it should never be had recourse to if that is ever so little above the normal.

But it is as a preventive of serious hepatic disease among sedentary or epicurean Europeans in the tropics, or, for that matter, in the land of their birth, who, either occasionally, frequently, or continually, experience a sense of fullness in the liver, that I wish to draw attention to the benefits they are certain to derive from the frequent practice of an experienced shampooer. Perseverance in such a course for the purpose of precaution will not, I am afraid, be submitted to by many. Yet, unless for the time involved and the slight expense, it has no drawbacks. As regards the *operates* (if I may use the expression), it is attended with a sensation of passive pleasure, and confers all the temporary benefits of Carlsbad or Cockle without any of their drawbacks. In the interest of the patients themselves, and for the sake also of giving the kneading a fair trial, the advice of a physician should be invariably taken.

Your obedient servant,

D. H. CULLIMORE,

Formerly Residency Surgeon at
Mandalay, Burmah.

Connaught Sq.,
London.

15th October, 1881.

Guy's Hospital.—At the opening of the Winter Session last week the following medals and prizes were distributed by the President: Gurney Hoare Prize—Edwin A. Starling. The Treasurer's Gold Medal for Surgery—Lockhart Edward Walker Stephens. Beaney Prize—Edwin A. Starling, St. Leonards-on-Sea. Michael Parris Prize.—Albert Martin. *Third Year's Students*.—Thomas Carr, First Prize, £35. William Thomas Frederick Davies, Second Prize £20. Walter Thomas Harris, Ipplepen, John Oacroft Littlewood, and John Henry Booth, Certificates. *Second Year's Students*.—Albert Martin, First Prize £25. Arthur Ernest Larking, Second Prize £10. Francis Heatherley, John Herbert Hawkins Manley, Thomas Hugh Miller, and Allan Gleisyer Minns, Certificates. *First Year's Students*.—George Elliot Caldwell Anderson, First Prize, £50. Reginald Maurice Henry Randell, Second Prize £25. Alfred Herbert Tubby, Ernest Willmer Phillips, and William Henry Bowes, Certificates. Open Scholarships in Arts, 1880—Richard Moody Ward. Open Scholarships in Science, 1880. Henry Walter Pigeon. Open Scholarships in Arts, 1881.—Albert Edward White. Open Scholarships in Science, 1881.—John Wychenford Washbourn.

St. Mary's Hospital Medical School.—Mr. A. R. S. Anderson has obtained the Scholarship in Natural Science, tenable for three years:—£75 the first year, £50 the second year, £25 the third year. Mr. W. Williams has obtained the second:—£60 the first year, £25 the second, and £15 the third.

NOTICES TO CORRESPONDENTS.

E. T. T.—When the articles originally appeared the subject was, for the first time, attracting general attention; since then numerous cases have been reported in this country, and the object of the later papers is to explain and illustrate not only the symptomatology, but, as far as possible, the pathology also of the condition. The publication is at present only in French, and can be procured through Messrs. Baillière, Tindall, & Cox.

A FATHER.—You are not by any means the only one thus deceived. If you press for a recognition of the service you will probably succeed.

DR. A. H. will please receive our best thanks for his kindly interest in the success of the journal.

GERM INOCULATION.—A correspondent having read Dr. Cameron's interesting paper on this subject in our last issue, thinks he has not done Dr. Bowdin justice in omitting to mention this author as the source of a good many of his facts.

INDIAN APPOINTMENT.—We are frequently asked by correspondents for information how to procure appointments in India and the Colonies. One such is offered in our advertising columns of present issue. A medical officer is wanted in India by the Wynaad Gold Mining Board who must have some experience in the treatment of tropical diseases. The salary is £700 per annum, and the engagement for three years.

MR. NEBBITT.—You will find all the information you require in our "Students' Number," Sept. 26th.

DR. MILWARD.—Thanks, the information will be valuable later on when we revert to the subject.

A PRUDENT.—Bryant's, Erichsen's, or Gant's "Surgery," either will answer your requirements, and all are reliable. Gant's "Guide to the Examinations" will also be useful.

HACKNEY SMELLS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of the 12th October there is a statement that I have received numerous complaints respecting oppressive smells from the Hackney sewers, and that neither our local authority nor the Metropolitan Board of Works has taken action in the matter.

I have to call your attention to a letter of mine in the *Daily Telegraph* to the effect that the Metropolitan Board, to whom the sewer belongs, has taken action against the firm causing the nuisance; that several adjournments have taken place, and that the case stands for hearing on the 20th inst., when it is expected that the works necessary to prevent the nuisance for the future will have been completed.

Faithfully yours,

JOHN W. TRIPLE, M.D.,
Medical Officer of Health for the
Hackney District.

INDIAN MEDICAL SERVICE CANDIDATES.—We are informed that the next examination for appointments will be held in London in February next. Copies of the regulations may be had on application to the Department, India Office, London, S.W.

MR. BERRY (Wigan).—Your communication is marked for an early number.

SYRUPUS HYPOPHOSPHITUM SEX.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly correct a typographical error in your notice of our *Syr. Hypophosphitum Sex* in your impression of this date. The analysis shows the presence of 1-8th grain of strychnine in each ounce, instead of 8-10ths as printed.

Yours faithfully,

ANDERSON & ADAMS.

68 Grafton Street, Oct. 12, 1881.

A TREATISE ON ANATOMY BY A NEW AUTHOR.

ANATOMY, oh Science to Sages delighting
To students of subjects the most uninviting,
Erat while the diploma all labour will sweeten,
We never, oh never confessed "we are beaten"
And now my young friends at your subject begin
By removing integument, otherwise skin.
And then you come down on some fascia and fat,
Nerve filaments, arteries, veins, and all that.
Still deeper are muscles, all sorts and all sizes,
Take a note, if you please, where each one arises—
Flexors, extensors, levators, constrictors,
Adductors, abductors, pronators, and sphinctors.
And now for a space let me claim your attention,
You'll remember I know all the things that I mention.
There are four little recti attached to the eye,
The femoral rectus is found on the thigh,
The rectus abdominus lies on the paunch,
While recti capitis from occiput branch.
Flexors in front of the carpus you'll find,
Extensors—still carpal—situated behind,
Quite other the "tip" for the foot you must know
Extensors of tarsus are flexors of toe.
You look on the shoulder for two heads of the biceps,
While beneath and behind are three heads of the triceps.
The pectorals cover the front of the sternum
By raising an arm you all can discern them.
Intercostals, my friends, you'll remember their place is
Betwixt rib and rib to fill up the spaces.
The gluteal muscles give strength to the hip,
While sphinctors compress both the anus and lip.
Behind in a gutter, on your back and mine,
Lie a thick mass of muscles, erectors of spine;
While again, both in man and his cousin the Lemur,
The adductors all cling to the lines on the femur.
The diaphragm crosses the trunk like a wall,
And keeps up your heart if it's given to fall.
(N.B.—The last phrase is not quite anatomical,
But a fellow to rhyme must at times do the comical.)
I've no wish, my dear friends, that you'd quote me *verbatim*,
The examiner might fancy you'd next want to "bate" him.)
In the thorax above are the heart, lungs, and pleura,
With aorta and ducts coursing down 'twixt the crura.
Beneath you have pancreas, liver, and spleen,
With coils of intestine oft laried between.
Not forgetting the stomach, duodenum, and colon
(My "sowl," how we'd puzzle the lawmaker Solon).
I hear some one mutter a hint to be smart,
Here goes. A "post-mortem affair of the heart."
This organ, my friends, you're aware, sends the blood
Right over the system in one endless flood,
Through arteries, so tortuous, down to the tissues,
Where it's caught up again by the veins at its issues,
And carried by them back again to the heart,
You'll see it all mapped out in—somebody's chart.
Auricle, ventricle, each right and left.
And before and behind is a fissure or cleft;
Within are seen valves to stay regurgitation,
I'll show them some day by a clear demonstration.
To ten points the clock—my colleague Doctor Jones
Will lecture to-morrow, at noon, on the bones.

—E. J. B.

THE INTERNATIONAL MEDICAL CONGRESS MEDAL.—The Secretary-General, Sir Wm. MacCormac, writes us that there are still a few of the medals which were struck in commemoration of this great gathering in London, to be had at the nominal sum of half-a-guinea, should

any member of the profession desire to possess himself of this souvenir of a never-to-be-forgotten Congress. Applications for these should be at once made to the Secretary-General's address, 13 Harley Street, London, W.

CHEMISTS' AND DRUGGISTS' (IRELAND).—W. L. M. asks: 1. Has any person who was practising as a chemist and druggist in Ireland before the passing of the Pharmacy Act of 1875 could now get registered as a chemist and druggist under Clause 31? 2. What is the address of the Registrar, and the amount of fee for registration?

[1. There is no registration of chemist and druggist in this country. Clause 31 was permissive with the Council, and they decided upon having no chemists and druggists. If anyone was in business before the passing of the Act his rights are reserved, but it is illegal for a new man to start as a chemist and druggist, even if he does not compound. 2. Mr. Fennell, College of Physicians, Kildare Street, Dublin.—Ed.]

FARMAR AND SEALEY FUND.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—It will be remembered that when the reports of the disaster at Majuba Hill on the Transvaal border reached this country public attention was called to the admirable manner in which certain medical officers and men of the Army Hospital Corps had distinguished themselves by their efforts to assist and protect the wounded under the peculiarly trying circumstances of that sad occasion. The gallant conduct of Corporal Farmar, A.R.C., was particularly brought to notice in the official despatches, and this non-commissioned officer has since had the special honour of receiving the Victoria Cross at the hands of Her Majesty the Queen at Osborne. When Corporal Farmar and another man of the Army Hospital Corps, Private Sealey, who had also made himself conspicuous by his attention to the wounded, and who, like Corporal Farmar, had been severely wounded himself while dressing them, reached Netley, it was found that both men had become incapacitated by the effects of their wounds for active manual exertions in the future. With the permission of the Director General of the Department, a subscription was then started by some of the medical officers, and officers, non-commissioned officers, and men of the Army Hospital Corps, with a view to supplement the Government pension which the two disabled men would receive in regular course on their discharge from the service; and my object in now writing is to state that this Fund, which at present amounts to £78, must shortly be closed. In the meantime, any additional subscriptions to the Fund may either be sent to the address of Surgeon-General Shelton, Head of the Medical Branch, 6 Whitehall Yard, who has kindly undertaken the trouble to collect subscriptions, or to myself, and I shall, with your permission, report hereafter the total amount of the Fund, and the manner in which it has been distributed.

I am, Sir, your obedient servant,
THOS. LONGMORE, S. GL., R.P.,
Prof of Mil. Surgery.

Netley, Oct. 10th, 1881.

P.S.—As the wounds of both Corporal Farmar and Private Sealey present some features of surgical interest, I send a short report of them. [These reports will be found on page 342.—Ed.]

Vacancies.

- Abbeyleix Union.—Medical Officer. Salary £80. Election, Oct. 25.
Birmingham General Dispensary.—Resident Surgeon. Salary, £150, with an additional allowance of £30 per annum. Applications to the Secretary before Nov. 14.
Bradford Infirmary.—Dispensary Surgeon to visit patients at their homes. Salary, £100, with board. Applications to the Secretary before Oct. 25.
Bristol General Hospital.—House Surgeon. Salary, £100, with board. Applications to the Secretary by Nov. 5.
Manchester Dispensary for Sick Children attached to the General Hospital.—Visiting Medical Officer. Salary, £150. Full particulars of the Secretary.
National Dental Hospital College.—Dental Surgeon and Lecturer in Dental Surgery. Candidates must possess the I.D.S. Eng. Applications to the Secretary, 149 Great Portland Street, London, W., by Oct. 25.
Rathfrum Union, Annamore Dispensary.—Medical Officer. Salary, £120. Election, Oct. 22.
Richmond Hospital, Surrey.—House Surgeon. Salary commencing at £80, with board. Applications to the Secretary before Oct. 22.
St. Thomas's Hospital, London.—Assistant Physician on the Staff. Fuller information on application to the Secretary.

Deaths.

- CURTIS.—Oct. 7, at Alton, Hants, William Curtis, M.R.C.S., in his 76th year.
HUGHES.—September 30th, Dr. Thomas Hughes, Oranmore, co Galway.
MAHAFFY.—Oct. 8, at Maidenhead, Berks, Surgeon-General E. Mahaffy, M.D., C.B., late of H.M. Bombay Medical Service.
MERRITT.—Oct. 2, at Beckford, Gloucestershire, William Gwillim Merrett, M.R.C.S., late of London, aged 87.
MURPHY.—On September 1, after a few days' illness, at Fort Labore, India, Surgeon-Major Robert Murphy, Army Medical Department, younger son of M. E. Murphy, Esq., of Limerick.
RAWSON.—Oct. 12, at Barrowville, Carlow, Thos. J. Rawson, M.D., aged 72.
SEXTON.—Oct. 11, at Hong-Kong, China, Septimus Sexton, M.D., Staff Surgeon, H.M.S. *Maggie*.
SIMPSON.—Oct. 18, suddenly, in Scotland, George A. Simpson, M.D. of Highgate, London, aged 36.
THOMPSON.—Oct. 3, suddenly, at 22 Hardwicke Street, Dublin, William John Thompson, M.D., M.R.C.S.E., aged 75.
WHITING.—Oct. 8, in London, suddenly, of heart disease, John Whiting, M.R.C.S., Surgeon of British India s.s. *Chryseus*.

STIMULANTS IN WORKHOUSES.—II.

THE BEER ALLOWANCE TO HEALTHY INMATES.

By NORMAN KERR, M.D., F.L.S., London.

In many workhouses it is the custom to give an allowance of beer, or other alcoholic liquor, to paupers who are not sick, while employed at various kinds of labour in "the house." An indoor pauper, for example, has to clean a few windows every day,—a task so arduous, a labour so severe, that many Boards of Guardians have deemed it requisite to support the strength of the hardly wrought, healthy inmate, by a pint of stout daily. This practice at once raises the question as to the need for the use of alcoholic drinks in health, and has nothing whatever to do with the administration of alcoholic liquors to the sick poor in the treatment of disease.

Are intoxicating liquors, then, to persons in ordinary health, a necessity, or a luxury? With the light that has of recent years been thrown upon the nature and effects of alcohol, there ought to be little difficulty in solving this problem. The living human frame is constantly losing substance, heat, and force. For any article of diet to be a necessity of healthy existence, such food, or such drink, must aid in repairing one or more of these losses.

Can intoxicants supply material to the body? They cannot. Containing no nitrogen, they cannot present us with flesh. Neither can they give us one drop of blood, one nerve cell, or one particle of bone. By the interference of alcohol with the natural functions, the elimination of effete matters from the body may be retarded, and, by the accumulation of these impure products within the economy, we may increase in bulk. This is not health: it is a diseased condition. No sound material does alcohol contribute to the healthy human organism.

Can alcohol supply us with fresh stores of heat to replace the loss that is ever taking place during life? There is no evidence to show that it can. The results of a vast number of experiments, made in all conceivable circumstances, go

to prove that, after an evanescent rise, the temperature goes steadily down. It is true that the surface temperature may be increased; but the internal temperature is *pari passu* decreased—the heightening of the temperature on the exterior being at the expense of the temperature of the interior. Our Arctic heroes found out the truth of this long ago, those who like Sir John Richardson best endured the extreme cold, recognising their extraordinary power of endurance to be the reward of their total abstinence.

If alcohol furnish us neither with healthy substance, nor with vital heat, can it not yield us new supplies of force? The excitement usually occasioned by alcohol is often mistaken for genuine power, but it is well known to physiologists, that the muscular strength is thereby lessened. Carefully conducted experiments have conclusively demonstrated this. So thoroughly alive are the commanders of ocean going vessels to the depressing influence of alcohol on the nervous system, and to its potent influence in the impairment of muscular power, that, when in severe weather they offer the inducement to their crews of a glass of grog, they take care that the reward is not served out till the immediate work is accomplished.

May, however, alcohol as a liquid, not yield us the fluid we are ever rapidly losing, and which is so essential to the due consistence of our tissues, the preservation of our personal identity, the conveyance of the plastic elements, and our natural automatic cleansing process. For all these indispensable objects, alcohol is valueless; not only so, but every addition of it to the fluid which alone can serve all these wise purposes, can be regarded as nothing but an adulteration.

Such is the verdict of science. And her testimony is corroborated by the evidence of experiment. The experience of some 10,000 men in our Indian army, of some 15,000 members of Her Majesty's forces at home and abroad, and of a vast multitude of persons of both sexes in every rank and condition in life, and in all climes, bears indisputable witness to the truth. Nothing can be clearer than that alcohol is not a necessity of healthy life. It is pleasant undoubtedly, once the taste for it has been acquired. It drowns care, and brings for a time the solace of oblivion to the suffering and the sorrowful. It is thus not a necessity

but a luxury—a luxury which cannot be enjoyed without being paid for, by a favoured few hardly at all, by large numbers at a very high price.

Alcohol, then, being but a luxury, always to be paid for, and rarely if ever indulged in except with some risk, is it right that paupers who are not ill should be supplied with this unnecessary and dangerous luxury, while many of the ratepayers, who have to bear the cost of these parochial luxuries, have a hard struggle to pay their rates? How many struggling taxpayers are there on the verge of pauperism, who cannot afford to purchase for themselves the luxuries they are at present called upon to present to fairly healthy paupers. In some workhouses this practice has been discontinued with most satisfactory results. In the parish of St. Marylebone, London, for example, £300 a year has been saved for the last six years, with no detriment to health, and with great benefit to the discipline of the house.

It may be said that this is the medical officer's business, and that all the responsibility for the beer allowance to inmates who are not unhealthy lies on him, his signature being essential to the confirmation of the allowance by the Local Government Board. This is, in a sense, true, but the necessary signature of the medical officer in such cases is, so far as he is concerned, purely formal. If it is the custom to give this allowance of intoxicants to paupers not sick, the medical officer is expected to sign the book as a mere matter of routine, and it would be difficult, if not impossible, for him to withhold his signature.

That the medical officer is not responsible for this practice may be seen from the following extract from a Glasgow paper:—"Bailie—gave notice of motion that all spirituous liquors supplied, other than those given by the medical officer's orders, shall be marked in a book to be kept by the governor, date, quantity, and name of party so supplied."

The manner by which this beer allowance to paupers not sick is legalized, is clearly shown in the following newspaper reports of proceedings at meetings of the Halifax and Westminster Boards of Guardians. Halifax—"Mr. —, in moving that no beer or other spirituous liquor of any description be allowed to any but sick paupers, and in all such cases only by special order of the medical officer, said the doctor informed him that hitherto the visiting committee had had power to order beer for able-bodied paupers in the house, but the sheets had been taken to him (the doctor) at the end of every quarter and he had initialled them. The very fact of the doctor initialling the sheets made the payment for the beer legal." Westminster—"The doctor was prepared to show the Board a large packet of orders written by the master and matron calling upon him to give porter to some inmates employed in some occupation in the workhouse. The medical officer would be very glad if they relieved him of entering all these names in his book. Mr. R — asked whether all the people whose names were on the list did work? Mr. B — replied that most of them did, and the others were under the doctor."

The following report of a part of the proceedings at a meeting of the Paddington Guardians affords also a clear exposition of the state of matters in many other workhouses:

"Dr. — was examined before the committee, and it appeared there were certain rules which the doctor found in existence which gave inmates over 60, and those working in the wood shed and in the laundry, a claim to the beer. The committee recommended that they should discontinue the issue of the beer in that old way, and allow it to be given only medicinally.

"Mr. F — said he understood it was illegal to give beer without a medical certificate, and he would like to know whether in Paddington beer was given according to the medical requirements, or because the people were over 60 years of age.

"The Chairman—There were 212 persons having beer in the house not being necessitated by an infirmity order.

"Mr. D — said the guardians for a long series of years

had been acting illegally, and they should stop it at once.

"Mr. F — said he had communicated with guardians of other Boards, and he found it was not usual to give beer except upon a medical certificate. In fact, it was illegal to do so.

"Dr. — said the present system filled the medical officer's books with cases that ought not to be there."

That this practice has not been confined to England and Scotland would appear from the following newspaper extract with reference to an Irish workhouse:—

"At yesterday's meeting of the South Dublin Board of Guardians it appeared that porter and whiskey were allowed to their inmates besides the sick and lunatics." This meeting took place some years ago, and whatever the practice formerly, I am informed by the master of the workhouse in question that healthy paupers engaged in work do not now get stimulants of any kind. Dr. Evory Kennedy, J.P., in his report on stimulants to the guardians of the South Dublin Union in 1878, testified on the authority of the clerk, that "intoxicating stimulants were dispensed to healthy servants, for various duties in the ward and about the workhouse premises, and not ordered by the medical officer."

Carefully looking over the House of Commons Return of 21st of March, 1871, one cannot help admiring the comprehensiveness of the pretexts on which the beer allowance has been granted to able-bodied paupers. Private families have constant trouble through the drinking habits of women who are occasionally employed to assist in washing; but many English unions appear to have thought it needful to treat their washerwoman to a more or less generous supply of malt liquor. In one union beer is given to washerwomen, cooks, scullery maids, extra night nurses, and whitewashers. In another, the baker and the laundress also partake of the daily luxury. In a third, the stokers, the pantrymen, the carpenters, and the sitters up with the sick come in for a share of the grateful beverage. In a fourth, the tailors are not, as in the first three instances, left out in the cold. In several unions the shoemakers, the furnace men, the engineers and the gardeners are also included in the beer ration. One union extends its liberality to all employed in mechanical work, and in the kitchen. Another gives stimulants to "old people and others who may be engaged as wardsmen or in household work." At a workhouse in the North of England, 1,386 pints of beer were supplied to the indoor paupers who were employed in labouring in the field and in the garden. The exercise of pumping water by two men was rewarded by a daily ration of a pint of ale each. The gallantry of two unions is evidenced by one, which gave no alcoholic drinks as part of their diet, allowing women ale on washing days; and the other allowing gin instead of beer to the nurse. In a workhouse not 40 miles from London, several inmates, employed as nurses, were allowed one pint of beer daily, and one had 4 oz. brandy.

The guardians of the West Derby Union, Liverpool, appointed a special committee on stimulants in 1871, which committee, after extended and elaborate inquiry, strongly recommended the discontinuance of the supply of ale and porter to able-bodied paupers, on the ground of this allowance being condemned by the orders of the Local Government Board. The committee also urged the impolicy of the beer ration, as tending to keep alive the taste for drink in those who, for the most part, had been impoverished and ruined by its use. They contended that if the pauper received a full and proper supply of good nourishing food, no labour should be required from him beyond what his natural strength, unaided by stimulants, would enable him to perform.

That the allowance of intoxicants to healthy paupers is contrary to the intention of the highest poor-law authority, is evident from the consolidated orders of the Local Government Board, as set forth in the following articles. Art. 107—The paupers shall be dieted with the food and in the manner set forth in the Dietary Table which may be prescribed for the use of the Workhouse, and no pauper

shall have or consume any liquor, or any food or provision other than is allowed in the said Dietary Table, except on Christmas Day or by the direction in writing of the Medical Officer, as provided in Article 108. Art. 108—Fourthly, that the Guardians may, without any direction of the Medical Officer, make such allowance of food as may be necessary to paupers employed as nurses or in the household work; but they shall not allow to such paupers any fermented or spirituous liquors on account of the performance of such work, unless in pursuance of a written recommendation of the Medical Officer.

So impressed have many Boards of Guardians been with the cogency of the arguments against the beer allowance to paupers not under treatment by the medical officer, presented by myself (at the Annual Conference of Metropolitan Poor-law Guardians, 1876) and others, that in a considerable number of parishes the allowance has been discontinued. Amongst the workhouses where no intoxicating drinks are supplied, unless for strictly medical purposes, are Manchester, Sheffield, St. George's in the West, St. Marylebone, and St. Pancras, London, Liverpool, Newcastle-on-Tyne, Gateshead, Chester, Wrexham, and Bridgewater.

In Manchester, Mr. Steinthal informs us, it was decided that all allowance of beer for work done by pauper inmates should cease, and that tea and coffee should be given instead. Several men and women left the house in disgust, but paupers were immediately found willing to take their places without having to resort to paid officials. The cases of drinking in the house ceased, quarrelling among inmates greatly diminished, and good order was more easily maintained. It is important to note that the health of the inmates in no way suffered. In an adjoining workhouse a similar resolution was adopted, but no substitute for beer was offered. Yet no difficulty was found in making the change, while a good result followed.

At a recent meeting of the Rugby guardians Mr. Henley, the Government Inspector, said he put the sick on one side as they were in the hands of the medical officer and the guardians would hardly interfere. But as regarded other classes of inmates it was a totally different matter. Every person in the house should work according to his or her ability, but receive no reward, directly or indirectly, for any work done. Therefore, it was perfectly clear that if stimulants were given by way of fee or reward, as they were given to men in the hayfield, it would be illegal. The only persons who might have them were those under the medical officer, and then only those he considered required them. He did not think himself that these should be given to nurses or washerwomen, while in the case of persons recently confined, the medical officer would certify in each case if he thought they required them. He (Mr. Henley) published some time ago a large sheet, showing the comparative expenditure in the way of stimulants, and how it had been abused for some time, and the result of this was that the allowance was discontinued in many places. It was then found that people often discharged themselves upon the abatement of the beer, a result most desirable, for it could be perfectly well understood that skulking fellows, if they could get a pint of beer in the workhouse, would rather go there than work for anybody else.

The effect of the authoritative allowance of liquor is to confirm the belief of workhouse inmates in the supposed strengthening and nutritious influence of beer and other kinds of strong drink. Surely, the faith in this English superstition, to quote Mr. Gladstone's happy phrase at the annual meeting of the Coffee Tavern Company in 1879, is implicit and widespread enough already, without the prejudice and acquired taste of those who are supported by rates levied on the industrious and thrifful, being consolidated by a more or less generous supply of alcoholic luxuries. The result of this questionable practice is seen in the insubordination and disturbance not uneldom occasioned thereby, and the unblushing drunkenness of so many indoor paupers on their day out. Some little time ago, the Sheffield guardians were discussing a statement publicly

made that 40 paupers had returned to the house drunk during the Christmas holidays. Though the master said that had been the quietest Christmas they had ever spent, it turned out that on Boxing day above 21 male paupers came back at night inebriated, and 16 did not return at all. At Bristol, not long ago, in reply to a question as to the cause of the backward state of the poor rate collection, the chairman of the Board of Guardians stated that the ratepayers would not pay because the guardians spent the money in wines and spirits. This declaration from the chair was elicited after reference had been made to the conduct of two nurses who had been drunk on a previous day. The chairman regretted to say that drunkenness seemed to be the normal condition of these ladies.

This system of part payment in liquor for work done is vicious in principle as well as disastrous in practice. It admits of no justification. A money payment, Dr. Evory Kennedy suggests, in his comprehensive report to the Stimulant Committee of the South Dublin Union, funded to give the earner a fresh start in life, would be infinitely preferable both for him and the ratepayer. As the Inspectors of the Local Government Board have shown, over and over again, the guardians have no right to get more work out of the pauper than he can fairly perform without the provocation of intoxicating stimulants. If the work be nauseating, a non-alcoholic stimulant like coffee would be much better for the pauper's health and have no demoralising influence. No temptation to the individual, and no disturbance of the peace of the establishment, would follow from an unintoxicating stimulus.

In very few cases has there been a temporary difficulty in withdrawing the beer. At Brighton, in 1873, it was resolved to discontinue the supply of intoxicating drinks except in extreme cases for which they should be specially ordered. To ensure the proper working of this change in the workhouse, it was decided to request the officials to accept a money payment in place of their liquor ration. Eight laundry women struck; but they were punished by the magistrate, and there was no further trouble. In one metropolitan workhouse, the medical officer felt he could not conscientiously legalise this beer allowance to healthy paupers by appending his signature. One of the guardians pathetically bewailed the sorrows of the ill-used able-bodied inmates thus ruthlessly deprived of their intoxicating luxuries, likening the taking away of this drink allowance to snatching away from a child a piece of bread and butter. Though this gentleman indignantly called upon the ratepayers to petition the House of Commons to interfere to prevent this "robbing the poor man of his beer," there was not enough virtuous indignation in the parish to evoke a favourable response. At Kensington Infirmary the doctor had thought it necessary to sign the book, as a matter of form, thinking it desirable for the healthy inmates doing work, to get beer. The guardians requested him not to do so, unless for any individual case requiring liquor for strictly medicinal purposes, a request with which he complied, and no complications ensued.

There will be little difficulty in securing the adoption of an improved system, if only the guardians and the master be gentle, and withal firm. For example, at St. George's in the West, London, the washerwomen, on their allowance being stopped, took their discharge. The guardians were very much alarmed in consequence, but the master, though not in favour of the change, by a little determination carried out the instructions given him, and there was, says Colonel Freenantle, no trouble.

The health of the inmates will assuredly not suffer from the discontinuance of the stimulant allowance to those who are in tolerably fair health. Past experience warrants us in going further and saying that their health will be greatly improved, their activity of body increased, and their enjoyment of life heightened.

A few months ago an interesting report of a successful experiment by Dr. Davies, Medical Superintendent of the Barming Heath County Asylum, showed the good results attained by the discontinuance of the ordinary beer allowance to both patients and attendants. In

March, 1878, the amount was diminished, and the change worked so well, that in November, 1879, he recommended the entire withholding of beer as an article of ordinary diet. Dr. Davies carefully weighed every patient and kept an accurate record, with the result that his opinion was amply confirmed. No unprejudiced person could question the good results achieved. Both patients and attendants were grateful for the change. Dr. Davies found, from the effects of alcohol on the patients under his care, that it was not advisable to supply them with exciting beverages, which had a tendency to prolong their malady, and conduce to a speedy relapse after their discharge in consequence of those inclined to over-indulgence retaining a taste for intoxicants.

A similar experiment at the Abergavenny Asylum is recorded in the 28th Annual Report. Of this experiment the Medical Superintendent, Dr. McCullough, says that skim-milk was substituted for beer at dinner. This alteration had been carried out without dissatisfaction, and with decided advantage. The Commissioners in Lunacy state that while some patients did not approve of the substitution of milk for beer at dinner time, to the larger number of those who were questioned on the subject, it seemed a matter of indifference which beverage was provided. The number of inmates at Christmas, 1880, was 534, and the average weekly cost of wines, spirits, and porter was reduced from £16 4s. 6d., in 1879 to £9 6s. 6d. in 1880.

If, in any exceptional case, alcohol be needed, that is a case for treatment by the medical officer. The character of the inmates will also be elevated, and discipline and order be more easily and effectually preserved. The marked change for the better secured by the absence of strong drink is strikingly shown in the experience of the Plymouth guardians. At a recent meeting it was reported that on Christmas Day, 1879, no beer had been, contrary to the former custom, provided. The result was, that the day was spent most comfortably, and to the satisfaction of all connected with the house. So unmistakable was the beneficial effect of the prohibition in 1879 that the guardians resolved to repeat it in 1880. What a contrast to the disgraceful Christmas dissipation at Sheffield, when twenty men returned to the house at night in a state of intoxication? In view of such evidence, who can object to the entire withdrawal of the liquor allowance to the healthy inmates of our parochial institutions?

NOTES FROM A COUNTRY PRACTICE.

By CAREY COOMBS, M.D. Lond.

SHORT sketches of cases occurring in general practice may be suggestive and useful, I therefore offer the following in the hope that they may interest the reader.

CASE I. Myelitis.—A young farmer came to me on December the 3rd, 1880, complaining of pains in his back which had existed for eight or nine days; he was unable to completely empty his bladder, and his bowels refused to act. On the 4th, he found his dorsal painless, but his feet were numb, and his gait was irregular—ataxic, and he had trouble in getting into bed. The patellar reflex was rather in excess on both sides.

An enema was required to relieve the bowels, and the urine was not passed without the catheter, which was accordingly used twice daily for twenty-one days, the period during which the bladder paralysis lasted. A soft india rubber instrument was employed, as being easy of introduction and not irritating the urethra.

Rest in bed and iodide of potassium in ten grain doses, thrice daily, were the only other remedies used, until the third week, when the legs were faradised. A wire brush electrode was applied to the parts round each ankle where the sensation was defective, for about five minutes every other day for a fortnight. The sensation and co-ordination being perfectly restored, treatment was suspended about

six weeks from the beginning of the attack. There was no reason to suspect syphilis in this case.

CASE II. Pyelitis.—A. A., æt. 24, a generally healthy young woman, a weaver, of loose habits, consulted me on account of severe pain in her left side, feverishness and rigors. From the time I first saw her (April 1879) she passed much pus in her urine. Her disease was complicated by her being five months pregnant.

In June I washed out her bladder with some warm water in which was a little very weak nitric acid, and on the next day (whether the injection brought it about, I cannot say) labour came on and she was delivered of a seven months fœtus. The infant is still living, a miserable rickety child.

After her labour the patient improved as to her general health, but matter passed from the rectum in October on two occasions, and in the urine continually, so that it appeared like dilute pus, and stank horribly. At this stage of her illness, and again a month later, she had a convulsion. In November, the left loin presented a flattened swelling, about three inches across, which was dull on percussion and fluctuated on pressure. As it showed no disposition to point I passed a fine trocar into the tumour over the 10th intercostal space, and procured about half an ounce of pus and some bubbles of pus. From this time the swelling diminished in size, though no fluid of any kind escaped from it after the puncture. But on the day following the puncture, and on two or three subsequent days she vomited purulent fluid of very bad smell, in quantities of five or six ounces. It is necessary to remark that the stomach had often rejected food previously to this last mentioned vomiting. From this period when so much pus was ejected from the abscess in the loin, from the rectum and stomach, there was a marked improvement in the patient's state, her pulse fell from 110 to 90, her skin was cooler, and her appetite returned, and in February of the next year, about ten months from the beginning of the attack she was able to return to her work in a hand-loom; her health has been very good ever since this illness.

CASE III. Long Retention of Ligatures.—A labourer, æt. 56, otherwise healthy, had suffered from caries of tibia for thirty years. The removal of a large quantity of softened bone from the right tibia seemed to aggravate the disease in that leg; on this account one year after the operation I amputated the limb at the knee joint, removing the condyles of the femur. Several ligatures were required, and an abscess formed in the posterior flap, from which one of them came away. This was four months after the operation, and the other ligatures were retained for long periods, the last not separating until the tenth month after the operation. This case is noted as an argument in favour of torsion, though most surgeons who have an operation case at a distance from home feel safer when the arteries are tied.

CASE IV.—A serious injury of the hand occurred to a lad of sixteen. He had charged a gun used for frightening birds away with gravel instead of shot, and when it was accidentally fired, the fragments of stone went through the centre of the palm of his right hand. The middle third of the third metacarpal bone was comminuted, but the hæmorrhage was small, and the wound of exit was less than an inch in diameter.

Some pieces of stone and of bone came away; the only treatment was constant application of carbolic water, and the wound healed firmly in eight or nine weeks. The season was favourable, the accident happened in April, and the hand was kept warm, fulfilling one most important condition in the healing of wounds.

CASE V. Sloughing Parotitis.—The patient was a young farmer, æt. 25, who, though not vigorous, was not the subject of any special constitutional defect. He first consulted me on account of pain and swelling at the angle of the jaw on the right side. Leeches were twice applied within the first week of the attack, constant fomentation with solution of belladonna was employed to relieve the great pain, the most nutritious fluid food, and

cinchona, were given to support the powers of his system. But the parotid gland sloughed, and on the ninth day of his illness his mouth was filled every few minutes with dark and most foetid pus. The whole neck was now swollen and red, and in the hope of preventing extension of the sloughing a free incision was made over the sternomastoid on the affected side, giving out a large quantity of dark brown fluid, and exposing a large ragged slough. It is not important to trace the daily progress of the disease, successive incisions were made as the necrosis of the cellular tissue went lower and lower, and large pieces of dead structures were removed from the wounds. At the time of his death on the nineteenth day, the disease had reached the lower border of the right pectoralis major, the acromion and the sternum.

There was nothing in the symptoms during the first few days of the illness to distinguish this case from one of ordinary mumps, until fluctuation was made out in the tumour.

ANIMAL VACCINATION. (a)

By CHARLES CAMERON, M.P.,

President of the Health Section of the Social Science Congress,

NATURAL cow-pock was so rare that had Jenner depended upon it, his discovery of its protective power could have come to nothing. Happily he discovered that cow-pock could be propagated upon human beings. Had the idea of propagating it on calves occurred to him it would have greatly facilitated his early labours, and have saved him from an accidental contamination of his lymph with small-pox, which nearly proved fatal to vaccination. His practice once established, Jenner had no occasion to change it, for he obtained wonderful results. As correctly summarised by the writer on vaccination in the "Encyclopædia Britannica," in the epidemics of Rotterdam, Montpellier, and Edinburgh, occurring between 1818-23, and described by different contemporary authors, the mortality among a large number of vaccinated persons attacked was only about 1 in 330 cases. On the other hand, among the small-pox cases treated in the London hospitals during the epidemics of 1870 to 1879 three-fourths of the patients had been vaccinated, and of these about one in every 10 died. In Jenner's day vaccination was conducted in what we should now consider a very inefficient manner, and yet the protection it conferred, as measured by the death-rate in cases of small-pox occurring in vaccinated persons, was ten times more efficient than that secured by the most complete form of vaccination practised at the present day; and twenty-five times greater than that afforded by our vaccination good and indifferent. As at present practised, vaccination still afforded a great protection against small-pox, but nothing comparable to that obtained in the early days of the practice. On the other hand, Dr. Cameron quoted from the experience of Belgium, Holland, and the United States, to show that the protection which animal vaccination afforded was even more complete than that recorded by early writers, and this he accounted for by the fact that those who practised it had adopted all the improvements which experience had grafted on the system pursued by Jenner. He accounted for the falling off in our results by a deterioration of the vaccine virus cultivated for thousands of generations on what Chauveau's researches had proved to be an unnatural soil. As illustrating this falling off, he exhibited a table giving an analysis of over 10,000 cases recorded in London in 1852-67 and over 4,000 recorded there in each of the periods 1871-78 and 1877-79. In cases exhibiting marks of cicatrices the mortality had in the first period been 7·6, in the second 8·15, and in the third 8·45. In cases classified as bearing good cicatrices

the figures were respectively 1·8, 3·32, and 4·70; in the best class—those recorded as showing four good cicatrices 0·87, 1·5, and 3·33, and so on, the falling off manifested being most alarming in the best vaccinated class of cases, while the percentage classified as good in each successive period also showed a marked falling off. These facts, Dr. Cameron maintained, were themselves sufficient to call for a change in our system. The motive which had originally given rise to the cultivation of lymph on calves was a desire to avoid all possibility of the inoculation of a loathsome human disease which had been frequently communicated through the ordinary virus. Such mishaps were in this country very rare, but the fact that they might occur, in the writer's opinion, rendered it the duty of the State which enforced vaccination to provide against all avoidable accidents. As to the possible dangers which anti-vaccinators had suggested might attend on animal vaccination, the answer was that when it was practised, as in Belgium, Holland, and the United States, no such accident ever had occurred, and, assuming their theory to be correct, the danger attendant on the operation was no greater than that which lay in every cup of milk or mouthful of meat consumed. No danger from inflammation attended the use of the cultivated animal virus—in fact, there was much less trouble from that than under the ordinary practice. For purposes of re-vaccination animal lymph presented a threefold advantage. It "took" in a greater percentage of cases; universal experience showed that much larger numbers of persons got themselves re-vaccinated when it was available than when it was not, and when required it could be produced in unlimited quantities. This was not the case with humanised lymph, which was always difficult to obtain when the presence of an epidemic rendered an abundant supply most urgent.

Clinical Records.

HUDDERSFIELD INFIRMARY.

Acute Synovitis of Knee, treated by Aspiration of the Joint and Subsequent Application of the India-rubber Bandage.

Under the Care of Mr. KNAGGS.

Reported by Mr. NORMAN PORRITT, House Surgeon.

J. G., a silk dresser, æt. 38, presented himself at Mr. Knaggs' out-patient room, having a swollen knee. He said that nine days ago, he knocked his knee against a projecting wheel, but feeling only temporary pain, he continued to move about as usual. On the next day, he had much pain in the knee, shooting up and down the leg, and in three days afterwards the knee was observed to be swollen.

Examination.—The right knee was puffed out by a large soft swelling, the outline of the patella being imperceptible to the touch. The joint was hot, and there was tenderness on pressure or movement. He was advised to come into the hospital, and on the next day, Sept. 23rd, 1881, he was admitted.

He was put to bed, extension upon the leg used, and immobility of the joint secured and maintained by a back splint. To the joint itself cold lotion was applied; but no perceptible improvement taking place it was decided to aspirate the joint. This was done with antiseptic precautions on Sept. 29th, and four fluid ounces of flocculent slightly turbid serum were withdrawn. The swelling had disappeared after the aspiration, and the previously tense joint was apparently near its normal size, the skin in front of it being rather loose. The limb being still on the splint, a porous india-rubber bandage was wound with considerable compressing force round the limb, beginning just below the tubercle of the tibia

(a) Abstract of a paper read before the Section at Dublin, October 4th, 1881.

and ending near the middle of the thigh. Since his admission the patient had required an anodyne at night, which was given on the evening of the aspiration.

Sept. 30th.—Bandage re-applied, rather slacker than before. The "knee-pain" has been much less severe, and he says he has passed the most comfortable night since admission.

Oct. 3rd.—Improvement continues. Has slept without morphia for last three nights, and there is a distinct diminution in the quantity of effusion in the joint, which has again swollen to half the size it first reached.

6th.—The patella is quite perceptible, both to the sight and touch. The temperature, which before the aspiration, reached 101° each evening, has gradually fallen to the normal height.

7th.—Extension of leg discontinued.

10th.—Bandage discontinued, and the knee was strapped.

12th.—Patient got up.

14th.—Discharged.

Remarks.—The above treatment recommended by Dr. Martin, of America, has in a fortnight's time, restored the acutely inflamed joint of a labouring man to a condition not far from that of the normal and healthy. There was no exercise of patience, whilst the inflammatory symptoms subsided under the use of evaporants and such like; no painting with iodine nor irritation by blisters, cauteries, or issues; no thickening or adhesions left in the joint requiring months to become consolidated or absorbed; no after stiffness nor lameness; but an useful, comfortable limb, enabling the patient to return to his occupation without long delay. The painlessness of the aspiration is also a feature of importance.

ROYAL VICTORIA HOSPITAL, NETLEY.

A Case of Extensive Ulceration of the Thigh caused by the Hypodermic Injection of Quinine.

Under the Care of Dr. G. HARRISON YOUNGE, A. M. D.

THE patient, M. S., was admitted into hospital, May 10th, 1881, with a circular ulcer, about six inches in diameter, situated on the anterior aspect of the right thigh. The ulcer was deeply excavated, and of a highly atonic character, presenting few granulations, and these being very flabby. It was surrounded by a border of bluish glistening skin, half-an-inch in breadth, which resembled in appearance, and in its great tendency to contraction, the cicatricial tissue that forms over the site of a burn. There was a profuse secretion of thin, highly irritating, and foetid pus.

History.—Six months previously, while serving in India, the patient had been attacked by a severe form of remittent fever. As the vomiting was incessant and prevented him retaining quinine when given by the mouth, this remedy was administered by hypodermic injection.

Shortly afterwards the skin around the puncture caused by the needle of the syringe became swollen and of a dark colour. This appearance rapidly extended, and after some days a large slough separated. The ulcer which remained assumed a most obstinate character, and resisted all treatment.

When I saw the patient I tried stimulating lotions, strapping, and skin grafting; yet, when he was removed from under my care, after a period of two months' careful treatment, the ulcer was only partially healed.

Remarks.—The above case is a good illustration of one of the great dangers of administering quinine hypodermically. The irritating properties of the medicine, combined with those of the acid used to dissolve it, have a most destructive action on the tissues. But this is not the only danger when quinine is thus exhibited. Within the last few years there have been several fatal cases of tetanus reported from India, which arose from giving quinine hypodermically. I think, therefore, that I am

justified in concluding that quinine should never be thus administered, or at least only in those cases where it cannot possibly be given in any other form. I believe that if it cannot be given by the mouth the only other safe mode of exhibiting it is by the rectum in the form of enema.

Special.

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

M. BOULLY, nothing daunted by the sweeping attack made by his friend M. Leblanc on the efficacy of inoculation in pleuropneumonia, entertained the Academie de Medicine on Wednesday last, during a full hour, in refuting all the charges brought against him by M. Leblanc, and citing facts which tended to confirm him in his opinion that the virus was susceptible of modifying the above disease when properly inoculated. If the virus be inserted otherwise than in the tail, it will produce a great number of tumours which develop rapidly. He had assisted last week in an official capacity, at experiments made on 25 animals, 13 of which had been already inoculated in the month of February last. These were again vaccinated, but it was observed the next day that the vaccine did not "take," which proved that the system was still under the influence of the primary inoculation, and consequently were proof against the disease.

INCISION OF THE PERICARDIUM.—Professor Rossenstein, of Leyden, has published recently a case of pericarditis with effusion, in a little girl, set. 10. There was no fever, yet the respiration and circulation seemed to be seriously compromised. Rossenstein punctured the pericardium with the needle of an aspirator in the fourth intercostal space, and drew off 620 cubic centimetres of liquid. Although the immediate effect of the operation was favourable, an effusion took place in the left pleura, and 1,100 cubic centimetres of serous liquid were withdrawn. Alarming symptoms set in, which necessitated a second tapping of the pericardium, followed by a considerable quantity of purulent liquid. After a third relapse, incision of the pericardium was determined upon, and with all the antiseptic precautions possible, an incision was made in the fourth intercostal space of an inch and a-half in length. The soft parts were divided layer by layer, and when the pericardium was reached exit was given to a great quantity of pus. Two drainage tubes were afterwards placed in the wound. The results were most satisfactory, the respiration and circulation returned to their normal condition, and at the end of four months the little patient was able to leave the hospital. This fact shows that purulent pericarditis as well as empysema can exist without any appreciable increase of temperature, and without any oedema of the skin, so that the aspirator is the only means of determining the nature of the effusion. Also this observation proves that the fear of finding in the heart vast organic lesions should not deter the surgeon from using the aspirator when considered necessary, as often these symptoms are only due to the functional troubles caused by compression.

INJECTION OF PHENIC ACID IN HÆMORRHOIDAL TUMOURS.—A Belgian *confrère* treats hæmorrhoids by injecting into the tumour by means of a Pravaz syringe, six drops of a solution composed of equal parts of glycerine and pure phenic acid. The pain consists in nothing more than a slight burning, which only lasts ten minutes. In a patient treated in this manner, and who had three hæmorrhoids, one of which, situated in the rectum an inch from the anus, measured the volume of a small hen's egg, it was found that the day following the injection the pile that had been operated upon had almost disappeared, the tumour seeming to be flattened against the rectal wall. A week later the second was injected, and with the same results. Finally, the third and largest was subjected to the same treatment, and in two days all trace of it had disappeared. Of course, the caustic properties of carbolic acid have, no doubt, considerable influence in effacing these tumours, yet the glycerine with which it is combined, must serve another purpose than that of constituting a vehicle for the acid. For it is well known that glycerine has what might be called an hæmostatic influence on bleeding piles, whether taken by the mouth or applied locally. A teaspoonful of glycerine taken three times a day will arrest the hæmorrhage in a very short time.

TAPPING IN HYDROCEPHALUS has never been considered an operation very encouraging, and classical books mention it as a last resource, and in language that does not conceal their doubts as to the success; however, it is refreshing that exceptions to the general rule crop up now and again. The following is one:—A young child, of twenty months, was brought to the Conception Hospital, Marseilles, affected with hydrocephalus, which made its first appearance only eighteen months before. The development of

the skull was rather rapid, for at the end of a year it had acquired the volume of an adult head. The frontal bone was particularly prominent, the sutures were largely separated, and the fontanelles considerably distended, fluctuation was very manifest. The eyes were prominent, but without strabismus. In the absence of any disorder of the sensibility or of movement, which are nearly always encountered in considerable ventricular effusion as in this case, tapping was decided upon as the only treatment indicated. The needle of the aspirator was inserted in the anterior fontanelle, and exit was given to 350 grammes of clear serous fluid, and very slightly albuminous. The head was then painted over with iodine, and the bones which were very movable, were maintained by little splints made by card-board, and kept *in situ* by a few turns of an india-rubber bandage. During the operation the child was slightly agitated and cried a little, which was considered to be the result of the faculty of function restored to the nervous centres by the evacuation of the liquid. A few hours after, vomiting came on, accompanied by a semi-comatose state which was very alarming but of short duration. The liquid was reproduced so rapidly that 150 grammes had to be withdrawn the next day. But from that moment all symptoms of meningo-encephalic irritation had disappeared, and the patient can now be considered as radically cured.

INFANTICIDE has become so frequent in France, that the *France Medicales* considers that the country is in danger of being depopulated. Never was morality at a lower ebb, and never was immorality more openly practised. Illegitimate births attain an exceedingly high figure in one week out of 850 births; over 300 were illegitimate (Paris). The journal quoted calls for energetic measures, demanding either the return of the turn-stile (*tourne*) or that maternal assistance should be given to the mothers of all illegitimate offsprings, and that the paternity should be sought for. The turn-stile was placed at the street door of the Foundling Hospital, the half of it containing a recess was turned towards the street. Into this recess the child was placed, and a bell rung. Immediately the child was turned in without the person who brought the child being observed. In this way the life of many a child was saved which, otherwise would have received an untimely end. But nevertheless it was an incentive to vice, and thus it was abolished.

At a quarterly meeting of the council of the Royal College of Surgeons, Mr. John Croft, F.R.C.S., of Brook Street, Grosvenor Square, was elected a member of the Court of Examiners in the vacancy occasioned by the resignation of Mr. John Marshall.

On Thursday last the body of Mr. H. J. Virgin, L.D.S. R.C.S., who practised as a surgeon-dentist at Oxford, was discovered in the Thames near that City. Several weights were found in his pocket, and there is no doubt that he committed suicide through the state of his monetary affairs. He leaves a large family.

We regret to record the fact that Dr. Norman Collier Maclean, who formerly practised at Bayswater, committed suicide with belladonna on the 8th inst. The deceased had been much depressed for some time previously, and had had sleepless nights. An inquest was held on the 10th inst., when a verdict was returned, "that the deceased committed suicide whilst in a state of unsound mind."

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 27, Bombay 26, Madras 34, Paris 26, Geneva 23, Brussels 22, Amsterdam 20, Rotterdam 17, The Hague 17, Copenhagen 17, Stockholm 14, Christiana 12, St. Petersburg 44, Berlin 23, Hamburg 17, Dresden 25, Breslau 26, Munich 30, Vienna 26, Prague 26, Buda-Pesth 28, Rome 21, Naples 39, Turin 19, Alexandria 47, New York 28, Brooklyn 21, Philadelphia 20, and Baltimore 26. No returns have been received from Lisbon and Venice.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 26, 1881.

FILARIA SANGUINIS HOMINIS.

SINCE the announcement, first made in 1872, that under certain conditions the blood of human beings may be found charged with minute nematoid worms, and that these bear an invariable association with some form of disease of the lymphatic system, the microscopic organisms to which Dr. F. R. Lewis gave the name *filaria sanguinis hominis*, have been a subject of patient investigation by several competent observers. For a considerable period the knowledge gained concerning them amounted to little beyond the facts of their existence and morphology, so that even in 1879, Dr. Cobbold, in the latest edition of his masterly volume on parasites, was unable to assert positively as to the genesis of the *filaria sanguinis hominis*, holding in contradiction to Dr. Lewis that the worm is genetically related to *Bilharzia*. The clinical history of the parasite had, however, even then received a much more complete explanation; and it had been well demonstrated that the mosquito insect was an essential agent in its development. Those patients who suffered from its presence exhibited certain definite symptoms, the most prominent of which had been assumed to be chyluria; and so far it was asserted that chylous urine was an invariable concomitant of the existence of

filariæ in the blood. Moreover, the disease was confined to those climates in which the mosquito made its *habitat*, so that little by little the life history of the worm became unravelled; and, at length, accumulated evidence points to its genesis as dependant on an alternation of generations, in which, however, there still remain more than one link to be discovered. In this country the disease has been wholly unknown, or, at any rate, unnoticed, until the advent of a patient at the London Hospital, in whom Dr. S. Mackenzie speedily recognised the symptoms produced by the presence of the parasites. This patient, a soldier, twenty-six years of age, had lived all his life in India, enjoying excellent health, and exhibiting no signs of the affection now troubling him until he had been some little time in England, having come here during the present year. A month after his arrival, he noticed that his urine was passed in greater quantity than usual, and quickly assumed a milky appearance. A month or so later pain was experienced in the loins and testicles, and almost pure blood was passed per urethram. Hematuria persisted for a few days, when the quantity of urine again underwent large increase, with a return to the milkiness, in which state it has since remained. Dr. Stephen Mackenzie first had charge of the case in August, and during the whole time he has observed it, it has presented all the characters of hæmato-chyluria. The condition of the excretion varies in several particulars at different periods; thus, that passed by day usually contains more blood and fibrin; the night discharge is more milky; the day urine is believed to contain more filariæ than the nocturnal. The especially remarkable features of the case, however, are presented by the characters of the blood; and it must be said that the care and skill displayed by Dr. Mackenzie in connection with it have been the means of obtaining, not only a fresh record of the facts already familiarised by the researches of other observers, but also of eliciting certain hitherto unascertained details of the greatest interest and importance, bearing on the history of filaria disease. During the day time, blood drawn from the patient (and for two months regular examinations of the circulating fluid have been carefully made every three hours) is found, under ordinary circumstances, to be free from filariæ; but in the evening, at about 9 o'clock, these begin to appear, and progressively increase to midnight, when they exist in greatest abundance. At 3 o'clock in the morning they sensibly decrease; at 6 o'clock but a few are to be distinguished; and at 9 they are not to be observed in the blood. This periodicity had been previously noticed and commented on by Dr. Manson, who enjoyed many opportunities of studying the disease in China. The particular discovery made by Dr. Mackenzie relates to the fact that a complete change of periodicity may be brought about by altering the relative times of sleeping and waking. When his patient spent the day-time in bed, giving the night hours to being about and active, filariæ appeared in the blood during the day, and were absent from it at night. Return to the ordinary arrangement was followed by a return of filarial migration to its previous course. These are the salient points in the case; their significance is as yet far from being deter-

mined. Dr. S. Mackenzie described and exhibited the case he has been so fortunate as to have under his care at the last meeting of the Pathological Society, the members of which then enjoyed the rare opportunity of seeing the living worms under the microscope. Beyond a statement of his experiences Dr. Mackenzie did not venture at that time, and it remains for future workers to assign the special pathological importance attaching to the various details.

Drs. Cobbold and Vandyke Carter, who are well-known in connection with the study of nematoid parasites, discussed the case before the Society, but they succeeded in throwing little new light on the mystery still surrounding *filaria sanguinis hominis*. That the worm requires for its due development the services of more than one "host" is now abundantly proven; as also is it that the human being and the mosquito are both concerned in its production. The filariæ of human blood are apparently embryonic forms which are received into the body of the mosquito at those times when the troublesome fly makes its raids upon men. It is, moreover, a curious coincidence that the immature worms should appear in the blood always at the time of evening, when the mosquito is most actively engaged in foraging. We must now, however, in consequence of Dr. Mackenzie's discovery, modify in great measure the inferences hitherto drawn from the coincidence, if indeed it be not further found that too much importance has in the past been attached to the phenomenon. That the mosquito does receive filariæ from its human victim needs no further demonstration, flies gorged with filarious blood having been again and again exhibited. These young filariæ, develop in the mosquito into sexually mature nematoid worms, which are subsequently liberated at the death of their host, the mosquito, which always makes its way to a collection of water to die. Thus far the history is certain; but in what precisely further progress consists, we are as yet unable to tell, since in some way there develops a worm nearly three inches long, the original filariæ averaging 1.75 inch long, by 1.3500 inch in diameter. The free mature worm finds access to the bodies of human beings in a similar way to that by which *dracunculus* gains a hold on its victims. What is the course of events regarding it when once *in situ* in the tissues, is another problem awaiting solution, the series of changes occupying the interval between such mature worms and the hæmatozoa found in the blood of Dr. Mackenzie's and all similar patients, being still unknown to science? It may indeed turn out that in these changes we shall by-and-by find elucidation of the many dark points surrounding our knowledge of the disease in which chyluria is a prominent symptom; and it can scarcely be more than profitless labour to speculate on them in the absence of such information. In this respect the discussion at the Pathological Society was commendable. Dr. Mackenzie taking the lead, those facts only were dwelt upon which are already firmly established, and it was left for a future occasion to enter into pathological details. Some few facts, notwithstanding, are even now worthy of note, about which there is still a suspicion

of improbability. Thus on the invariable or occasional relation of chyluria to filariæ in the blood, some authorities, as Dr. Vandyke Carter, assert that chyluria is produced only in cases where the parent worm is lodged in some part of the urinary tract; others insist on the constancy with which chylous urine is a symptom of the disease; but it should be said that Dr. Carter paid exceptional attention to the subject for a lengthened period, and that his observations deserve the highest consideration. Again, it is tolerably clear that filariæ may exist in the blood without any untoward symptom arising to indicate their presence, a fact difficult to associate with invariable chyluria in such cases. It may even be that Dr. Mackenzie's patient while in India had been infected with the worm, but that not until he became submitted to changed conditions of life in England was a stimulus afforded to its development. How long, and in what manner, the parent worm may exist ere giving birth to the embryonic nematodes, we know not as *flariæ sanguinis hominis* is, as we have said, as yet a mystery, and thus are we without the means of determining what is probably the most important point in connection with the whole question of the disease.

Dr. Mackenzie's contribution is exceptionally valuable in that it is an accurate and reliable record of what he has seen. Its worth is only increased by the avoidance of theoretical explanations, and we feel sure that the result of it will be to lead up to a better and surer knowledge than we yet possess regarding the subject treated in it.

THE ROYAL COMMISSION ON MEDICAL REFORM.

THE early date at which the Royal Commission has resumed its hearing of evidence affords us a most gratifying assurance that the Commission "means business," and intends to be ready for the meeting of Parliament with its programme of medical reform. The alacrity of Lord Camperdown, its chairman, is in delightful contrast with the slothfulness of the General Medical Council, now hibernating. The Royal Commission has commenced its winter's work, as we stated last week, with the examination of the representatives of the Irish Colleges of Surgeons and Physicians, the Irish Medical Association, and the Irish "grinders," and—if these gentlemen told their minds without reserve—we doubt not that the Commission heard much which they did not know before. We shall not know until the Blue Book appears what questions these witnesses were asked, but we hope that it was not forgotten to institute a few straightforward inquiries about Irish sham certificates, about monster curricula intended to be paid for but not studied, and about the credit fee system which diverts the money of the lecturer into the pocket of the apprentice farmer. "The truth, the whole truth, and nothing but the truth," is wanted for the enlightenment of legislators, and no one could give it with more authority than the Irish witnesses of last week, especially the gentlemen who represented the "grinding" interest.

It is, indeed, somewhat surprising to note the appa-

rently blank ignorance of the General Medical Council as to the abuses of the Irish system, and it is difficult to understand why that august body should be so completely uneducated on the medico-educational doings of one of the three medical kingdoms over which it is supposed to rule. Is it possible that not one of the six members of the Irish Branch Council has ever breathed a word in all these years about the Irish schools and hospitals which sell certificates to all comers for hard cash, without requiring even the pretences of an attendance on the courses of study represented by those certificates? Is it conceivable that the General Medical Council has never learned from the Irish members that its recommendations have been for years past treated with silent contempt. If so, it is obvious that the "intelligence department" of the Council is ridiculously inefficient. If not, the Council itself is, by the indifference with which it has treated the disgraceful condition of the Irish system, self-condemned.

OPHTHALMIC TEACHING IN DUBLIN.

THE Irish medico-educational world is just now somewhat disturbed by a contest between those who wish the Irish student to learn something of eye surgery and those who wish to catch and keep students on any terms. A couple of years ago the board of Trinity College and the Council of the Irish College of Surgeons determined on requiring from all students a three-months' course of clinical ophthalmological study. Thereupon the various hospitals of Dublin proceeded to consider how they could comply with this requirement; some of them added special ophthalmologists to their staffs and made special arrangements for teaching the subjects, while others, being prevented by unalterable arrangements from doing this, decided to send their students to one of the special eye hospitals and to pay the regulation fee for them. There were, however, other hospitals which thought it unnecessary either to appoint a specialist or to have their students instructed by one elsewhere; and they met the difficulty simply by dubbing one of their ordinary staff ophthalmologist, and throwing into the bargain with all the other valuable evidences of study granted by them an additional *gratis* testimonium of special education in eye surgery.

To this profitable little arrangement, however, there are one or two objections: The College of Surgeons—in the first place—refuses to accept certificates of special instruction granted by a non-specialist surgeon who has no adequate means of teaching the subject, and it has, therefore, decreed that every hospital which issues such certificates must have eight beds exclusively occupied with eye diseases, an ophthalmoscope room, a special out-patient department, and special days and hours for seeing patients and teaching. In the second place, the hospital teachers are themselves in revolt against the granting of certificates without additional fee. They have, they say, years ago bound themselves in a common compact to charge the same fee all round, and they won't stand any hospital giving the eye certificate *gratis*, not to say without study. A meeting of representatives from all hospitals in Dublin to discuss this point was

held on Saturday last at the College of Physicians, and it produced no satisfactory result. The delegate from Mercer's Hospital was called to explain why that hospital had—in breach of the fee compact—advertised in italics that it would grant the fee without charge; and the reply given was that the hospital had done it and would continue to do it, in which defiance it was backed by Jervis Street Hospital; and the meeting adjourned for a week without achieving unanimity.

We venture to submit that the teaching of ophthalmic surgery to students who may, next year, have to practise it on the persons of the sick-poor is not a question of fees, however important some people may consider that element to be. In our opinion hospitals might be allowed to charge what they pleased for their courses of instruction, if only we could be sure that those courses were honest and adequate; but that is exactly what cannot be hoped for if the certificate is to be only a piece of parchment thrown into the scale to catch idle and impecunious students. No teacher worthy of consideration has ever yet devoted, or is ever likely to devote his time to *gratis* instruction, and any pretence to make such instruction *bonâ fide* must inevitably end in the reduction of it to the category of a sham and an evasion. We are distinctly of opinion that if the medical staff of any hospital is not prepared to admit an ophthalmologist to a share of the pupil fees, or else to remunerate such an officer for his services by a special fee for his certificate, it is impossible that educational justice can be done to the student as regards the speciality within its walls, and no licensing body ought to accept its certificates.

But, whether or not a fee is charged, it is quite evident that in Dublin, colleges must, in future, be vigilant against such evasions of their requirements as have been attempted in this instance. The day of shams, we venture to hope, is past, and if the ophthalmic testimonium is to be merely an addition to the bundle of receipts for money which are, in Dublin, mis-called certificates of attendance, we hope the Council of the College of Surgeons will at once repeal its ordinance, and leave the licentiate to his pristine ignorance of ophthalmology.

Notes on Current Topics.

Manchester Royal Infirmary.

A GOOD deal of regret will generally be felt that the board of management of the Manchester Royal Infirmary are compelled to appeal for special assistance on behalf of the institution under their care. During the last few years a very considerable falling off in the income received by the charity has taken place, the receipts in 1879 having been £24,253, while in 1881 they reached no more than £19,841. In consequence of the serious differences it has been found absolutely necessary to draw on the capital account since June, 1876, £59,972 having been taken from this source to meet current expenses over and above subscriptions. The yearly excess of expenditure over income has been steadily

increasing of late, until now it stands at upwards of £8,000. The management of the infirmary declare that unless increased support is afforded to the hospital to this extent per annum, they will be compelled to close some portion of the building, since it is impossible for them to continue the suicidal policy of living on capital, which has lately been rendered absolutely necessary. Appended to the report is a declaration bearing the signature of Mr. Lund, the surgeon, to the effect that beneficial changes have followed the completion of the alterations commenced some time ago for the purpose of putting the building in a more satisfactory sanitary condition. Pyæmia, erysipelas, &c., which used to be of no infrequent occurrence, are now but rarely seen; but the improvement involved an outlay of £23,000. We trust that Lancashire cotton kings will not long permit the chief hospital in the county to want for funds.

The Action of Digitalis on the Cardio Rhythm.

KAUFMANN has been experimenting afresh as to the action of digitaline on the heart, and the following was his conclusions (*Le Praticien*):—1. That the inhibitory fibres of the heart are paralysed by the digitaline, since under its influence these fibres when excited lose their power of arresting the beating of the heart. 2. That this paralysis affects the peripheral extremities, seeing that the periphery of these nerves is no longer excitable. 3. That the acceleration of the beats of the heart becomes more and more pronounced in proportion as the excitability of the nerves diminishes. 4. That the acceleration reaches its maximum at the moment when the excitability ceases, and that it ought consequently to be attributed to the gradual paralysis of the peripheral extremities of the inhibitory nerves of the heart. 5. That very small doses of digitaline produce a slowing of long duration, whilst large doses immediately produce acceleration without preceding slowing. 6. That the inhibitory fibres paralysed by the digitaline regain their excitability in proportion as the poison is eliminated. From this, in conclusion, M. Kaufmann draws practical inference; when in treatment one wishes to slow the beating of the heart, we should use very small doses of digitaline; we thus obtain the slowing without much consecutive acceleration.

Testimonial to Mr. Cantlie, F.R.O.S.

At the annual students' dinner of the Charing Cross Hospital, held on the 18th inst. at the Holborn Restaurant, the chairman, Mr. James Cantlie, M.A., F.R.C.S., Demonstrator of Anatomy in the medical school attached to the hospital, was presented with a valuable gold watch and a purse containing £20 by the students of the school. The hearty good-will with which the address accompanying the present was received by the students assembled, was a gratifying testimony to the esteem and good-feeling with which Mr. Cantlie is regarded by his present and past pupils. It is always a pleasant sign when such occurrences as this mark the relations between teachers and their classes; and in this case we can equally congratulate the recipient of the testimonial on the evident regard experienced for him by those who contributed to the gift; and likewise the students who made it, on the

excellent manner in which they showed their admiration for one who has done much to help them in their work. The dinner was attended by, among others, Dr. Pollock, Dr. Forbes Winslow, Dr. Henry Green, Mr. Barwell, &c., &c.

Elimination of the Pancreas.

TRAFOYER published a case where the pancreas was eliminated by stool, the individual recovering. Chiari, in the *Wein. Med. Woch.*, 1880, publishes two new cases.

An individual, 38 years of age, suffered from violent pain in the epigastrium, with vomiting; after a few days' remission, he presented all the symptoms of intestinal occlusion, no purgative having any effect. Finally, after a period of alternating diarrhoea and dysentery, the patient found one day in the discharges a cylindrical mass about thirteen centimetres long, which M. Chiari recognised as a part of the pancreas, still having its excreting duct. This mass must have passed by perforation, from without inward, either into the intestinal canal or the stomach.

At the autopsy of a woman who had presented signs of generalised peritonitis, the pancreas was found in the midst of a purulent mass; the middle portion of the duodenum was perforated from without inward, as also the transverse colon. There has been abundant hæmorrhage from the ulcerated pancreatic duodenal artery. No cause could be assigned for these accidents.

An Ancient Pharmacy.

BEFORE pharmacies were thought of the dispensing of medicines was in the hands of the clergy. One of the first pharmacies was in Halle (Prussia). It still exists, and is known as the Lion Apotheke. It was established in 1555 by Wolfe Holzwirth, under the patronage of Archbishop Sigismund, which dignity prescribed at the same time a kind of prohibitive law for the inhabitants of Halle, which ran as follows:—Be it enacted that: No one in our town of Halle openly or secretly prepare or sell confections, tablets, ointments, plasters, fats, or things made with sugar, such as simplicia or composita, decoctions, tiriac, colloquintida, or other substances which belong to the exclusive privilege of the apothecaries.

Œdema Glottidis.

A PATIENT was, on Friday last, brought into Guy's Hospital, who was found to be dead on admission. No reason could be assigned by the friends of the deceased to account for the state in which he then was. He was described as having been found near the hospital, crawling with difficulty along the road; and when interrogated, declared himself to be on the way to consult a doctor, thus evidently indicating that he was suffering acutely. Post-mortem examination made on the body within twenty-four hours, revealed nothing at first sight to account for the sudden death, the chief abnormality apparent to naked eye inspection being œdema of the lungs, the tissue of which organ was otherwise fairly healthy. Heart, kidneys, and liver were normal to all appearances; as also was the brain. Somewhat puzzled by the case, the pathologist proceeded to examine the stomach, on the theory of poisoning. The viscus, however, contained only a pint of alcoholic,

beery-looking fluid, in which were masses of undigested meat; but there was nothing to suggest either an irritant or other poison. A foreign body in the larynx seemed the only remaining possibility; and on carefully investigating this organ, there was found slight œdema of the aryteno-epiglottidean folds on either side, thus at once offering an explanation of the whole event, taken in conjunction with the condition of the lungs and with a slight fulness of the ankles which was subsequently noticed. The case is an instructive one, as showing how easily this cause of death can be overlooked in the absence of distinct œdema of the part, and also as illustrating the rapidity with which post-mortem changes may bring about complete dispersion of the collection of fluid which primarily asphyxiates. Doubtless, had a complete history of the case been obtainable, sufficient evidence would have been forthcoming to suggest the probable cause; and this reference to it may prove serviceable in future instances of a similar kind.

Carbolic Acid for Carbuncles.

DR. J. T. WOODS, of America, gives the result of several experiments with carbolic acid in the treatment of carbuncles. He describes the treatment on a patient suffering with two carbuncles, one on the back of his head, the other below it on the neck. He loaded a hypodermic syringe and, passing the point through the openings and into the sloughing mass in every direction, completely saturated it with the pure acid and awaited results. In a minute all the smarting disappeared, and with it all pain and all sense of soreness. He again charged the instrument and thrusting it through the skin over the other carbuncle, in a variety of places, soaked the whole carbunculous mass beneath the skin, enough of necessity escaping to fully bathe the borders, modify inflammation, and destroy any septic elements then developed. In a few moments all the pain and soreness was gone in this also. The skin over the mass became quickly white, hard, and dead, and in a few days detached, in the form of a slough, the interior mass also becoming rapidly loosened, only requiring the cutting of a few shreds to remove it, when the cavity was found to present a satisfactory appearance and rapidly filled up, leaving an exceedingly small cicatrice. The remarkable feature in this case was that after the complete saturation of the carbunculous mass no pain occurred, the patient going about his ordinary labour without discomfort. Dr. Woods advises the use of the pure acids only, and to complete saturation. Dilution would increase, if not create, danger of absorption of the acid, converting a very simple procedure into a condition of great danger, and insufficient quantity defect the purpose for which it is used.

PHILIP HOYOL, artist, of Breslau, recently committed suicide in the Hampstead Road by burying his face in cotton wool saturated with chloroform.

THE *New York Medical Record* recommends nitrate of amyl as a very effectual remedy in chordee and painful priapism:—three to five drops by inhalation is the proper dose.

Guy's Again!

THE principle on which the ward administration of Guy's Hospital is conducted under the existing *regime*, has more than once served as subject of comment in these pages; and on one occasion we had to draw attention to the fact that the rule by which nurses were called on to administer medicine to patients led to the commission of a blunder very nearly involving loss of life. During the past week a somewhat similar *contretemps* occurred, though fortunately attended with no ill consequences. Though the rule by which nurses performed the duty of giving physic when prescribed does not now obtain, we believe, it yet may be undertaken by lady pupils, and one of these, the daughter of a gentleman renowned in medical circles, handed to a patient in the ward under her, a glass containing carbo-lic oil, in sweet ignorance apparently of the fact that there are essential differences between this substance and castor oil. The incident is instructive so far that it demonstrates the mistakes not only likely, but certain to occur wherever indiscriminate license is granted to novices in the art of nursing. It must, however, result injuriously not only on patients who run the dangerous risks sometimes incurred, but also on the institution where such mistakes are known to be possible; and it offers us one more warning against permitting the perpetration of existing abuses.

The Irish College of Physicians.

As we reported in our last issue the annual stated meeting of this College was held on Tuesday, the 15th, being St. Luke's day. Dr. George Johnston was re-elected President, and Professor Helmholtz, who visited Dublin last April and received the degree of LL.D., *honoris causa*, from the University of Dublin, and the Honorary Fellowship of the Royal College of Surgeons in Ireland, was elected by acclamation an Honorary Fellow of the College. Drs. J. W. Moore, Harvey, Macan, and Nixon were elected Censors; and Drs. Benson, Churchill, and Foot, additional Examiners, to take the place of an absent Censor or Examiner. The additional examiners in the subjects of the first professional examination elected, were Dr. Duffey (in *Materia Medica*), Dr. Nixon (in *Anatomy*), Dr. Pursar (in *Physiology*), and Dr. W. G. Smith (in *Chemistry*). Drs. Churchill and Kirkpatrick were elected Examiners in Midwifery. The outgoing Treasurer, Registrar, Librarian, King's Professor of Midwifery, Professor of Jurisprudence, and representative on the General Medical Council, were re-elected. The President appointed Dr. J. W. Moore Vice-President of the College. The Provost of Trinity College having attended and administered the statutory oath to the Fellows of the College present, they proceeded to elect by ballot to the vacant King's Professorship of *Materia Medica* and Pharmacy, and, *ex officio*, Physicianship of Sir Patrick Dun's Hospital. Dr. Walter George Smith, Physician to the Adelaide Hospital, was elected. Dr. Walter Smith succeeds his father, Dr. Aquilla Smith, in the chair which the latter has recently resigned. He is the author of the well known *Commentary on the British Pharmacopœia*, and of many valuable papers and reports on subjects relating to *materia medica* and pharmacy.

Celluloid.

CELLULOID is a complex product formed by mixing nitric cellulose (proxyline) with camphor dissolved in alcohol, this product is laminated and compressed. From it is obtained a hard, elastic, transparent material, which takes a brilliant polish. By the addition of other materials, celluloid can be rendered opaque, to imitate ivory, ebony, coral, &c. First discovered in 1869, in America, and afterwards manufactured exclusively at New Jersey, celluloid has for some years past been prepared at Stains, near Paris. Submitted to the action of heat, it softens up to 80° centigrade, and then is fit for moulding; it regains its hardness when allowed to cool. Celluloid ought to be preserved from any appreciable rise in the temperature so as to prevent serious accidents, for it is a very combustible body, and should only be stored in small quantities. Its preparation takes a long time, and requires a great deal of care. By the addition of a certain quantity of fatty oil, celluloid can be obtained in a flexible state, and thus rendered useful for collars, cuffs, shirt-fronts, &c., instead of linen, it can be easily and rapidly cleaned. Up to the present time the principal use of celluloid has been the manufacture of toys. Some time ago it was utilised to make the blocks of engravings for printing. The leaves which are used for this purpose are 3 mm. in thickness, they produce very fine and durable blocks. In fact, celluloid is a curious product, which is presented to us in many different aspects, and has various remarkable uses.

Action upon the Fœtus of Medicine taken by the Mother.

USING the microphone, Dr. Kubassow has observed the effect on the heart of the fœtus of medicines taken by the mother (*Dissertation: Russisch. Centralb. für Gynakol.*) 1. Chloroform and chloral-hydrate, he finds, have first a stimulant, then a sedative effect on the fœtus, this last effect being evidenced by the dulness and infrequency of the heart's beat, and the greater quietness of the fœtus; They act within five to ten minutes, chloral more powerfully than chloroform, and especially so if given per rectum, 2. Opium and alkaloids cause prolonged irregularity of the heart's beat in the fœtus, acting more slowly, but for a longer period than chloral or chloroform. Opium acts more powerfully per os than per rectum, 3. Digitalis has also a powerful and prolonged action on the fœtus. Dr. Kubassow believes, from chemical examination, that a dose of chloral hydrate taken by the mother is divided within fifteen minutes between herself and her child, in proportion to their weights. The practical conclusion is, that more than thirty grains of chloral hydrate will be dangerous to the child, if given at once per rectum, or repeated sooner than in half an hour. The same holds for one and a half grains of opium, as tincture, repeated sooner than in an hour.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population, were — Leicester 14, Bristol 15, Portsmouth 16, Norwich 16, Plymouth 16, Leeds 17, Sheffield 17, Dublin 18, Newcastle-on-Tyne 19, Salford 19, London 19, Oldham 20, Sunderland 20, Bradford 21, Brighton 21, Edinburgh 21, Wolverhampton 21, Manchester 21, Birmingham 22, Glasgow 23, Nottingham 25, Hull 26, and Liverpool 27.

The Society for Relief of Widows and Orphans of Medical Men.

THE quarterly Court of Directors was held on Wednesday, October the 12th, the chair being occupied by the President, Sir George Burrows, Bart. The court was unusually well attended. The deaths of two of the oldest members of the society, Dr. Billing, V.P., and Mr. R. C. Griffiths were announced. Two new members were elected. The deaths of two widows were reported, one had been in receipt of grants since 1833, receiving for herself and children the large sum of £2,272, the husband having been a member for only nine years, paying but 18 guineas. Applications were read from 60 widows, nine children and three recipients, from the Copeland Fund, and a sum of £1,250 10s. was recommended to be paid to them at the next court. The expenses of the quarter were £37 15s. The treasurer reporting favourably on the state of the funds, the directors resolved to give the same present this Christmas as last to the widows and orphans receiving grants. An application was approved of from one widow, and a grant of £30 was given to an orphan towards his self-maintenance.

Health of Dublin.

THE monthly report for September of the Medical Officer of Health on the state of public health in Dublin says, that the deaths within the metropolitan area during the five weeks, were 19·12 per 1,000. The deaths within the city were in the ratio of 21·24. The deaths from the seven principal zymotics were, in the whole district, 1·64 per 1,000. As compared with August, the admissions of typhus fever to hospital were about equal; there was a large increase in admissions of scarlet fever cases; a slight increase of typhoid fever cases, and a small falling off in admissions of fever patients.

The following shows the steady improvement which has taken place:—

Death-rate per 1,000 from all causes—

Feb.	March.	April.	May.	June.	July.	August.	Sept.
44·25	34·60	31·78	27·05	23·7	22·37	20·27	21·24

Death-rate from seven principal zymotic diseases—

Feb.	March.	April.	May.	June.	July.	August.	Sept.
4·15	2·45	2·16	·2	1·96	2·1	2·62	1·96

The zymotic deaths in this month and June are the lowest recorded, allowance being made for the increased accuracy in registration which recent legislation has effected.

Dr. Cameron thinks that the improvement in the state of public health in Dublin is, in some measure, due to the important sanitary works carried out in the city during the last two years. It is, however, necessary that the improved cleansing and paving of the city, the shutting of hundreds of old tenement dwellings, the more general use of water-closets in the tenemental dwellings, should be followed up by the erection of a large number of dwellings for the most humble and the most dependent classes of the population. There is a great dearth of dwellings for these classes, owing to the closing of 841 houses and hundreds of single rooms and cellar dwellings since August, 1879.

During September, 42 houses and 38 rooms and 22 cellar dwellings in other houses were closed, being unfit

for human occupation. Orders to close 39 other houses were obtained.

Surgical Society of Ireland.

THE election of Council of the Surgical Society of Ireland, for session 1881-82, will take place in the Royal College of Surgeons, on the first Monday in November. The ballot will commence at four o'clock p.m., and terminate at five. Members of the Society, being fellows of the College of Physicians, or of the College of Surgeons, are alone eligible or entitled to vote.

Candidates are required to send their names to the Hon. Sec. on or before Monday, the 31st instant.

Nocturnal Enuresis of Children.

PROF. GROSS advises the following:— (*Louisville Med. News.*) Strychnia. gr. j., pulv. cantharid. gr. ij., morph. sulph. gr. iss., ferri pulv. ℥j.—to be made into forty pills or powders, and one given three times a day to a child ten years old. They will speedily relieve the irritation of the bladder, especially if conjoined with such measures as a cold bath daily, the avoidance of irritant food and late suppers, the patient lying on the side or belly, not drinking for a few hours prior to sleep, and emptying the bladder on going to bed.

Military Officers on Medical Duties.

FOR the time being, it would appear that so far as British interests in India are concerned, there is a lull to war's alarms in that dependency. True, there are rumours of one small expedition in prospect: its object being, as usual, to punish a Border tribe. But such an expedition is, in itself, of little account; it can at best absorb but a very small number of military officers who have no more important functions to perform than those of "general duty-wallahs." Hence, perhaps, the anomaly of constituting a committee, composed of combatant officers, for the purpose of investigating a purely medical matter, namely, the causes and mortality of cholera in the Punjab. There is, indeed, a medical officer on that committee, but only as secretary. But to all intents and purposes its "executive" composition is precisely similar to that of a council of war, or court martial, court of inquiry, or other tribunal purely military in character, appointed for a purely military purpose. Surely, the officers so appointed must feel that they are altogether placed in a false position; besides the extremely unpleasant circumstance that they are expected to perform a duty, of the qualifications for which they are necessarily ignorant.

Consultation with Homœopaths.

THE autumnal meeting of the South Midland Branch of the British Medical Association was held at Leighton Buzzard.

The following resolution was adopted: "That under no circumstances do we consider it right to meet in consultation any practitioner of homœopathy; and that this Branch very much regrets the remarks on the subject of homœopathy made by the readers of addresses at the last annual general meeting at Ryde."

Poisonous Patent Medicines.

A Miss ASHFIELD recently died from the effects of an overdose of chloral. Deceased was a confirmed invalid, and eccentric. The servant of the deceased and her medical attendant deposed that she was found quite cold and stiff. She was lying with her head on the edge of the bed, with one hand placed over her mouth and nose, which were distorted. Under the bed was a medicine glass, which had been rinsed out, and on a stand by the side of the bed was an empty bottle, which had contained syrup of chloral. Deceased was in the habit of taking chloral, but against express orders. The chloral came from the University Stores, London. She had obtained thence several bottles of chloral. No respectable chemist would sell chloral in such large quantities as deceased purchased it, and without the order of a medical man. The bottles were labelled "Hunter's Solution of Chloral," but without the name of the seller, or the word "Poison." The bottles were covered by the three-halfpenny medicine stamp, and clause 16 of the Pharmacy Act excluded patent medicines from its operation. The Coroner remarked on the unsatisfactory nature of the Act, which permitted poisons to be distributed wholesale by the London stores without any precautions. After a brief consultation, the jury found a verdict as follows: "That we consider further precautions should be taken by persons who sell such articles, and that the bottle should be labelled 'poison,' notwithstanding the exemptions apparently provided by clause 16 of the 'Sale of Poisons' Act; the chloral having been issued as a patent article."

The Entries.

THE entries at the various hospitals for the present Session have now been completed with the following results:—St. Bartholomew's, 164 full entries, 6 occasional students; University College, 106 full, and 41 for preliminary science course; Guy's, 81, and 3 dental students; St. Thomas's, 65 full, 29 occasional; St. George's, 63 full, 3 occasional; King's College, 56; Charing Cross, 38 full, 6 occasional; Middlesex, 33 full, and 21 special students; St. Mary's, 21; Westminster 20 full, 3 occasional; Owens College, 80 full, 6 for preliminary science course; Durham University, 125, 35 of whom are first year's entries; Bristol, 29.

Indian Medical Items.

A COMMISSION, consisting of Colonel Hall as president, Mejors Stephen and King Harman as members, with Surgeon-Major Bellew as secretary, has been appointed to inquire into the causes and mortality of the cholera epidemic which lately passed over the Punjab. This committee has commenced its sittings at Murree, and is now visiting the principal cities of the province. The epidemic, which is known as *choleraic fever*, is still raging at Umritsur. It is generally agreed that it is due to the late excessive rainfall.

A new portable camp filter has been issued to all divisions in the Bengal Presidency, for the use of troops on the line of march and in cholera camps. For the present it is not intended for use in barracks.

THE Governor-General of India has been pleased to make the following appointments to his personal staff:—

To be Honorary Surgeons: Surgeons-General W. R. Cornish, C.I.E., and A. J. Payne; Deputy Surgeon-General W. J. Moore, Brigade-Surgeon J. A. Marston, Surgeons-Major G. Farrell, T. E. Charles, M.D., R. W. Cunningham, M.D., and C. A. Atkins, and Surgeon A. H. Rowe—all of the Army or of the Indian Medical Service. These appointments are similar to those of Honorary Surgeon to Her Majesty the Queen in this country.

Vaccination Fees for Workhouse Surgeons.

THE important case of Dr. Simpson and the Board of Guardians of Dover, was before the County Court judge last week, and decided. Dr. Simpson formally brought an action against the guardians for £38 18s. for 137 cases of successful vaccination performed by him in a period of fourteen months, during which he acted as the house-surgeon to the workhouse. The guardians did not dispute the claim, but they were disinclined to discharge it in consequence of an objection raised by the Local Government Board on the grounds that the appointment of medical officer had not been confirmed by them. The judge gave a verdict for the plaintiff for the full amount.

WE regret to learn that Surgeon-General Donville, C.B., Honorary Surgeon to Her Majesty the Queen, succumbed to an attack of typhoid fever last week at Haalar Hospital. We hope to publish a full obituary notice of the deceased in our next.

NEW YORK is apprehensive of a water famine, and the Mayor of New York has issued a proclamation to the inhabitants calling their attention to the perilous state of things caused by the long drought. The inhabitants are therefore exhorted to practise economy in using water, as, unless copious rains set in shortly, the entire reserve supply will be exhausted in sixteen days at the present rate of consumption.

DR. WALTER G. SMITH has been elected to the King's Professorship of *Materia Medica* in the Dublin School of Physic, and he becomes—*ipso facto*—Clinical Physician to Sir Patrick Dun's Hospital. As the Board of Trinity College has made it an essential that no professor shall hold any physiciancy elsewhere than in Sir Patrick Dun's Hospital, Dr. Walter Smith vacates his office in connection with the Adelaide Hospital. A vacancy in the staff of this hospital is thus created.

DR. A. COPPINGER, resident physician to the Mineral Water Hospital, Bath, having resigned that appointment, after eleven years' service, the patients and servants at the hospital presented him last week with a handsome time-piece, accompanying which was the following address:—"Mineral Water Hospital, Bath.—To Dr. A. Coppinger.—The patients and servants of the above institution beg to assure you, on the occasion of the severance of your connection therewith, of their sincere regret at your departure, and ask your acceptance of the accompanying time-piece, as a small mark of their esteem and regard, with their hearty wishes for your future success."

FROM diseases of the zymotic class in the large towns last week scarlet fever showed the largest proportional fatality in Hull, Nottingham, Sunderland and Leicester; in Hull no fewer than 33 fatal cases of this disease were recorded, making 286 that have occurred since the beginning of July. The 44 deaths from diphtheria included 13 in London, 10 in Glasgow, 5 in Edinburgh, 5 in Portsmouth, and 5 in Birmingham. The highest death-rate from fever occurred in Oldham and Salford. The fatality both of measles and whooping-cough was below the average. Small-pox caused 25 deaths in London and its outer ring of suburban districts, and one in Bradford; no fatal case of this disease was recorded in any of the other large towns.

Scotland.

(FROM OUR NORTHERN CORRESPONDENTS.)

ELECTION OF PRESIDENT OF THE COLLEGE OF SURGEONS.—At a meeting of the Fellows of the College last Wednesday, Mr. Francis Brodie Imlach was a third time elected to fill the Presidential Chair. A more fitting compliment, and one more richly deserved, could scarcely be paid to any man; and the generous tribute paid by Professor Spence to Mr. Imlach's disinterested devotion to the duties of his office met with a hearty and genuine response from the Fellows present. Among the many obligations, mentioned by Mr. Spence, which the College owes to Mr. Imlach, not the least is the almost tender interest taken by the President in the Extra Mural School. The lecture-room of every lecturer in the School has been visited, and a kindly word of encouragement has been addressed to the younger members of the School. Although at times we have been constrained to animadvert severely on some of the doings of the College, yet we cannot but recognise the disinterested devotion to duty which has signalised Mr. Imlach's tenure of office.

EDINBURGH UNIVERSITY COURT.—At a meeting of this Court, held on the 17th inst., the Earl of Rosebery, Rector, in the Chair, it was reported that the committee appointed to dispose of the application of Mr. D. J. Hamilton, M.B., for recognition as a teacher of medicine in Edinburgh, whose lectures on pathology should qualify for graduation in medicine, had directed recognition to be issued in his favour. Mr. William Dittmar, Ph.D., was re-appointed to be additional examiner in Chemistry for the year ending 30th December, 1882. It was ordered to be published that at the stated meeting in January, the Court would proceed to the appointment of the additional examiners in surgery, clinical medicine, and institutes of medicine for the next period of office. Dr. J. D. Cunningham was appointed assistant to the professor of anatomy.

THE LATE DR. G. A. SIMPSON.—This promising and accomplished medical man was interred on Monday, the 16th inst., in Nellfield Cemetery, Aberdeen. Dr. Simpson died suddenly, at Banchory, from heart disease, at the early age of 36. During eleven years he enjoyed an extensive practice at Highgate, London. He studied at the University of Aberdeen, London, Paris, and Berlin; and graduated in 1868 with the highest academic honours. His maternal grandfather was parish minister of Lechel-Cushine; his father was connected with the Indian Medical

Service, and died in India. Dr. Simpson was married to a daughter of the late Professor MacRobin, by whom, and a young family, he is survived.

EDINBURGH HEALTH SOCIETY.—If the public health of Scotland is not soon improved it will certainly not be for want of public medical lectures. Platform oratory of this nature is assuming the form of a mania in Scotland; and one does not know which most to admire—the disinterestedness of the lecturer, or the versatility of their talents. A public meeting, to inaugurate the Edinburgh Health Society was held on the 21st inst., in the Free Assembly Hall, Edinburgh. The object of this Society is to promote the observance of the laws of health in Edinburgh and neighbourhood. There was a large attendance, both lay and professional; but the poor, for whom this Society is intended, were, as usual, conspicuous by their absence. Lord Shand, in the absence of the President elect—Lord Rosebery—was called to the Chair. Professor Douglas MacLagan, Mr. Trayner, Advocate, and others took part in the proceedings.

EDINBURGH—HEALTH STATISTICS.—The deaths in Edinburgh during the week ending with Saturday the 15th inst., were 94, including nine country deaths. This is equivalent to an annual mortality of 19 per 1,000, and is five below the weekly average of last year. Eight deaths from zymotic diseases occurred in the old town, four of them being from diphtheria, and two in the new town, while no death from zymotic disease was reported in the southern suburbs.

FIFE AND KINROSS LUNACY BOARD.—At a meeting of this Board, held at Cupar on the 18th inst., a letter was read from Dr. Fraser, Her Majesty's Commissioner in Lunacy, thanking them for the honour the Board had conferred upon him, but that, considering his official position, he could not accede to the request to recommend a successor to Dr. Brown, late medical superintendent of the asylum. On the motion of Dr. Cleghorn, it was agreed to recommend to a special meeting of the Board that Dr. Turnbull, of Morningside, should be appointed.

THE ROYAL DISPENSARY, EDINBURGH.—In compliance with a request of the medical officers, the directors of the above charity have changed the hours of attendance of the medical officers from two to three o'clock. We regret that the advantages of the dispensary are not more appreciated by students, there being a great falling off in those attending the practical pharmacy department. This is probably owing to the institution by the University, of a practical pharmacy class, practically another means of adding three guineas a student to the professor. As most of the Scotch graduates go south on graduating, the teaching in the university class is a waste of time, for it does not fit them for the duties of an assistant, a most important preparation for practice. Surely, something might be done to make the dispensary pharmacy class more attractive.

EXAMINATIONS AT THE COLLEGE OF SURGEONS.—At the examinations of the College held last week, out of eleven candidates only three passed. As far as we can gather, the examinations were fairly conducted, so that the rejections point to a deplorable want of proper preparation on the part of candidates. Dr. Inglis has resigned his post of examiner, and is succeeded by Dr. Macnair whose chief qualification for the office of examiner appears to be the fact that he is the parochial medical officer for North Leith.

EPIDEMIC OF SCARLET FEVER IN GREENOCK.—Scarlet fever has assumed something like epidemic proportions in Greenock, about 100 cases being at present known to be

under treatment by the sanitary authorities. In the hospital there are about 80 cases, and, as the ordinary fever ward was found insufficient for the accommodation of the patients, an additional ward has been opened for their reception. At first the disease was confined to working class families, but it has since broken out among the residents in the west-end of the town. On an investigation it seems that nearly all the families whose members have been attacked, have been served with milk by a person named James Holms, a farmer in the neighbourhood of the Cloch, in the parish of Inverkip, one of whose households was recently "down" with the distemper. The Sheriff interdicted the selling of the milk from Holms' farm.

Correspondence.

MR. BURDETT ON HOSPITAL EXPENDITURE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue for October the 12th, you published a paper read by Mr. Burdett before the Social Science Congress held in Dublin during the present month, in which it is said that the in-patients at the Leeds General Infirmary cost (I presume in 1878) £3 0s. 4d. per week. As this is such a serious error I should be glad if you will allow me space to say that the cost per patient per week at the period named was about 19s. 4d. not £3 0s. 4d. as stated by Mr. Burdett, I should also be glad if you would insert the following table:—

In-patients under treatment.	Average daily No. of in-patients resident.	Average No. of days in the Infirmary.	Out-patients under treatment.	Total expenditure under all heads.
3,763*	228	23	18,225*	£12,582 5 1

The in-patients cost per week about 18s. This sum is small as compared with many other Hospitals, and is much less than at the Seamen's Hospital, Greenwich, where Mr. Burdett was Secretary-Superintendent till the beginning of this year. It is a most difficult matter to compare hospital expenditure accurately, without knowing precisely the basis of management in each particular case. For instance, in some hospitals, the patients have to provide their own tea, sugar, and butter; the resident staff have to provide their own food and washing. In the Leeds Infirmary, everything is found for the patients and the resident staff. Again, some hospitals are built upon what is known as the *block* plan, others upon the pavilion plan, those of the latter class cost more in working expenses, but they have many advantages in a sanitary point of view. I enclose a copy of our last annual report.

I am, Sir,

Your obedient servant,

THOMAS BLAIR, General Manager,

Leeds General Infirmary,
17th October, 1881.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The importance and the necessity for the most able and experienced physician to read carefully, and to understand thoroughly, the notes of the case before giving his diagnosis, were never more completely demonstrated than by the letter of Dr. Carpenter, which appears under the above heading in your last issue.

If Dr. Carpenter will refer to the abstract of my paper on "Hospitals and the State," which appeared in the *Medical Press and Circular* of the 12th inst., he will find that in order to enable the public to arrive at a just conclusion on the points treated, I endeavoured to give a review of the working of different systems of hospital management at several

* These were all individual cases, not the same people registered several times over during the year.

classes of hospitals during the last five years. In this retrospect I included an abstract from a leading article which appeared in the *Times* on the 13th November, 1877, which was not contradicted at the time, and which contains the particular statement which has filled good Dr. Carpenter with the "utmost astonishment." No one can rejoice more than I do that in Alderman Stone the governors of St. Thomas's Hospital have found a treasurer who has conducted its affairs with discretion, intelligence, harmony, and success. This fact does not in any way invalidate my argument that the system of management at the larger endowed hospitals in this country is not the best system. It simply proves that a capable man, having his heart in his work can, in spite of the many difficulties which are incidental to such a system, conduct the affairs of a great hospital with satisfaction to the medical staff and to the governors.

The error into which Dr. Carpenter has fallen is the more surprising, because you gave the footnote marked "b," which clearly showed that the whole paragraph was merely an abstract, and that it referred to events anterior to the appointment of Mr. Alderman Stone as treasurer to St. Thomas's Hospital.

The letter of a physician to the North-West London Hospital I have also seen, and I beg to assure him that before publishing my paper, and the tables attached to it, I will take care that his hospital is duly noted.

I am, Sir,

Your obedient servant,

HENRY C. BURDETT.

39 Gloucester Road, London, N.W.

THE BATH HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The comments you were pleased to make in your last issue on the anomalous state of things at the Royal United Hospital, Bath, will doubtless have good effect. When I first went to Bath, I inquired of the porters if medical men were allowed to see the hospitals—the Royal United, and Bath Mineral Water Hospitals, and was told, no. I have been practising in Bath more than twenty years, and have not yet seen the wards of the hospitals. Now, my opinion is, that all public institutions should be open to the public, especially hospitals to medical men of the place. It would be of great advantage to young medical men to see cases and operations, cases that would not be seen in private practice; it would give them nerve for operations, and increase their knowledge for treating disease. It would be beneficial to the public, who would be the gainers by their medical attendants seeing the practice of others.

Most medical men would be glad to subscribe to the hospitals, if they had a right to do in Bath, as they can do in London. At Cambridge they send round a notice to the profession of any great operation. I have seen Chopart's amputation of the foot performed there, and never since.

As you have made a movement in a right direction, I hope it will be followed up for a general advantage.

I am, Yours &c.,

FRANCIS P. HOBLYK.

Bladud Buildings, Bath.

THE NOTIFICATION OF INFECTIOUS DISEASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to express my concurrence in Dr. Martin's excellent letter on the Notification of Contagious Diseases Bill in this day's *Medical Press and Circular*. Absence from Ireland prevented my taking part in the recent discussion on this question at the Social Science Congress, as I should have been glad to have supported Dr. Jacob (to whom, as also to the distinguished medical member for Dublin, Dr. Lyons, M.P., we owe so much for their action in this matter) in his opposition to the proposed attempt to degrade the position of the medical profession.

I have no doubt that those who have so actively interested themselves in promoting this Bill are acting in the best faith, and with the best possible intentions, for what they think the public interest. But no amount of respect for the personal motives of others should prevent us from deprecating and

opposing any measure which we regard as impolitic, and which we know to be unjust.

The proposal to compel medical men, *bon gré, mal gré*, to act as sanitary detectives may possibly become law. But it is utterly impossible that such a law could ever be carried into effect, unless medical men themselves consent to undertake the "happy dispatch" of their professional character by the violation of that professional confidence, which has been so unhesitatingly, and heretofore so safely, reposed in them by the public.

As physicians, our first duty is to our patients, and our second is to our profession and to ourselves. That the medical profession has been ever ready to do the State some service needs no demonstration. The record of its unpaid, arduous, and hazardous services in the hospitals and public charities of the country may well bear comparison with those of any other calling. But there is a limit even to medical endurance, and the State can surely have no right to call on any medical practitioner, and more especially on one who is not employed in the public service, to undertake duties which he regards as prejudicial to the public welfare, as well as at variance with his patients' interest, and opposed to his own sense of professional honour.

I rely too much on the wisdom and justice of the legislature to anticipate that such a measure will be enacted. But should it pass into law, I am certain that very few, if any, physicians will be found disposed to give that co-operation (without which, as I have already said, the proposed measure would be practically useless) in carrying out the provisions of a law totally opposed to their sense of duty to their patients and their profession, as well as entirely miscalculated for the purpose for which it is intended.

I am, Sir, yours, &c.,

THOS. MORE MADDEN.

55 Merrion Square, Dublin,
Oct. 19th.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I object to being compelled to notify infectious disease among my patients, not only on the general principle of its being a violation of professional secrecy, but because it would make me a party to carrying out a law in which, as far as I can see, no provision is to be made against a manifest injustice. It is all along covertly assumed, that a person is to blame because he has infectious disease in his house, and therefore it is no matter, though he should suffer penal consequences. One speaker has said, that it would be better a shopkeeper should be ruined, than that his shop should become a centre of contagion. Even you say "the danger to the neighbourhood is of his making." Now, I contend, that the danger is not of the householder's making; that in nine cases out of ten, the disease comes into his household, from circumstances over which he has no control. Nay, if he be a poor man, the public at large, and especially the wealthier portion of it, are responsible for his having to live among surroundings, which cause infectious disease to be rife. It is a glaring injustice to punish people by closing their shops and the like for the public benefit, when the public itself has brought about the conditions which cause the mischief. Any law is most unjust which does not provide for giving compensation whenever loss, by closing a shop, keeping lodgings unlet, and the like, has been incurred through the presence of infectious disease. Such a shopkeeper has as much right to compensation, if his business is injured for the public safety, as a farmer has for the cattle slaughtered to stop the cattle plague. If this principle were carried out, the motive for the concealment of infectious disease would be removed.

Yours &c.,

FIAT JUSTITIA.

CONSULTING WITH HOMŒOPATHS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I believe you need be under no apprehension with regard to the effect on the profession at large of the generous advocacy of liberality to homœopaths inculcated at the Ryde meeting by Dr. Bristowe and Messrs. Barrow and Hutchinson. The heart of the great body of representative men of the orthodox persuasion is still in the right place, according to your views. No fear of the illustrious heads of the medical faculty—such as the titled physicians

of the metropolis—weakly allowing themselves to be persuaded to desist from boycotting and rattening their homœopathic colleagues whenever occasion may offer. Indeed, to my surprise and consternation, I lately discovered that the principles of the Anti-Homœopath League had penetrated even to the hitherto indifferent operating surgeons, for one of the most eminent of these, Mr. Lister, lately refused to hold any professional intercourse with me in reference to a patient to whom I had called him in on account of a dislocated arm, on discovering that I was favourable to the homœopathic treatment. In all my thirty-six years of practice in London I had never been so treated. Indeed, actual Presidents of the College of Surgeons, notably Quain and Ferguson, have repeatedly done the surgical part of the treatment in patients whom I was attending medicinally, and treated me with the utmost cordiality. But, it seems, *nous avons changé tout cela*, that is to say, if I may judge by my treatment by Mr. Lister; and the word has gone forth to operating surgeons to make them also practise the same boycotting manoeuvres to homœopaths as have been always employed by illustrious physicians of the Gull and Jenner stamp. Of course I may be mistaken, and Mr. Lister's anti-homœopathic zeal may be peculiar to himself. He has not been a long time away from Edinburgh—my native town—where medical polemics, as a rule, rage more fiercely than in the metropolis, but he is an eminent man, and perhaps his example may have an effect on the other operating surgeons of London, and then we shall see the edifying spectacle of patients left unrelieved of their broken and dislocated bones, or of their over-distended bladder, until they consent to turn off their homœopathic attendant.

Yours faithfully,

R. E. DUDGEON.

53 Montagu Square, London, 19th Oct.

VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The International Medical Congress of 1881 will always be remembered gratefully if for only one circumstance, and that is because Mr. Pasteur announced at that meeting that *pox pua*. In consequence of that letter I was honoured by a visit from the other authority on this important point, Mr. Badcock, formerly of Brighton, now resident in London at 87 Kennington Park Road. That gentleman was good enough to leave for me a still rarer work written by him on the question of the origin of vaccinia. As it is out of print, I think your readers will gladly see some extracts from it which I now enclose. The work is thus entitled:

"A Detail of Experiments confirming the power of Cow Pox to protect the constitution from a subsequent attack of Small-Pox, by proving the identity of the two diseases, by John Badcock, chemist, Brighton. Henry King, Bookseller and Stationer to the Queen Dowager, 1 North Street, and 44 East Street, Brighton, 1845."

We read in this classical pamphlet in page 11, "Towards the end of the year 1836, I suffered severely from a dangerous attack of small-pox, which happened but a few months after re-vaccination, and my mind having previously been impressed with an idea that the old vaccinia had lost its protective influence by passing through so many constitutions, during the long period of forty years, I was exceedingly anxious to procure some fresh from the cow, for the purpose of having my own children re-vaccinated. On inquiry, I found that the true disease seldom prevails among cattle; and I also learnt, from very excellent authority, that disastrous consequences have arisen from inexperienced persons communicating other pustular diseases of the animal in mistake. The only satisfactory mode of obtaining, with certainty, the true vaccine that presented itself to my mind was, therefore, to inoculate a healthy cow with small-pox matter, as the result of that operation, if any, must be cow small-pox. I must here mention that this method of obtaining vaccine is opposed to Dr. Jenner's theory; for he informs us that the origin of vaccine was a disease on the heel of the horse, called the *grease*." Page 14. "Having, as I have already stated, lost some of my confidence in the old vaccine, and being desirous of avoiding the risk of taking the casual disease from the animal, I solicited some of my medical friends to inoculate a cow of mine with small-pox, but their want of leisure from professional duties disappointed me in that respect, and, after waiting nearly three years, I undertook the experiment myself."

"In the month of December, 1840, I commenced operations on a fine young cow, with small-pox matter taken from a strong healthy girl, and was singularly successful. My own little boy was the first vaccinated from the cow, and from this and subsequent operations I have carefully kept up the supply of vaccine. In these proceedings the utmost caution was observed for the public safety, as well as to make the experiment interesting to the profession. Three days after the inoculation with small-pox, the cow was inspected by medical men, the vesicle was watched in its progress, and the lymph taken in their presence. I also placed all my early cases of vaccination under the inspection of medical practitioners, and a great number of them visited my little boy during the progress of the disease."

"After my success in this experiment, the next was to inoculate a pony with small-pox, but without any result. I was equally unsuccessful with three cows which I inoculated with grease (the reputed source of Dr. Jenner's vaccine), for in all I failed to produce anything like a vaccine vesicle. It was not until some time after the commencement of my investigations, nor, in fact, before I had succeeded in my object, that I became acquainted with the experiment of Mr. Coely, of Aylesbury, made a few months previously, and so beautifully illustrated in the eighth volume of the 'Transactions of the Provincial, Medical, and Surgical Transactions.'

Page 16. "The following extract from a lecture by Mr. Erasmus Wilson confirms the opinion that cow-pox and small-pox are identical:—'We may,' says this clever surgeon, 'regard vaccine in another and its true light, namely, as identical with variola, and consequently the operation are the same with inoculation with small-pox, the only difference being the greater mildness of vaccine, resulting from its transmission through the cow. In this sense it is clear that variolation, after vaccination, is re-vaccination in all excepting in name.'

Page 17, "In a work published by Mr. Pruen in 1807, entitled 'A Comparative Sketch of the Variolous and Vaccine Inoculation,' the opinion of a Mr. Birch is quoted, that 'cow-pox was nothing but small-pox transmitted through the cow.' All these authorities, therefore, favour my view of the question, and tend *à priori* to show that the lymph obtained from vesicles produced on the cow by inoculation with small-pox matter, would cause on the human subject the usual effects of a perfect vaccination. This fact, as I have before stated, I have repeatedly demonstrated by direct experiment."

"I have already remarked that my own little boy was the first human being whom I vaccinated with the lymph which I obtained from the cow. The operation was perfectly successful, and one of the medical gentlemen who had witnessed the development of the vesicle upon the cow, became desirous to vaccinate his child from mine."

"Although I had the greatest confidence in the lymph thus produced, and infinitely preferred it to the old stock of doubtful origin, which appeared to be worn out, yet as it was the first experiment of the kind I had ever heard of, I naturally watched its transmission with some anxiety. My little boy's novel case exacted considerable interest, for more than thirty gentlemen of Brighton and the neighbourhood, including six physicians, visited him during the first ten days."

Page 18. "Notwithstanding the unanimous opinion of all regarding my child's case, I thought it advisable to subject most of the patients of the first and second removes from the cow to the same scrutiny; the results were equally gratifying. Good vesicles were produced, and the children did not appear to suffer more constitutional disturbances than is usual from the ordinary vaccine."

"By the kind co-operation of the profession in furnishing me with frequent supplies of small-pox lymph, I have been able, during the last four years, to repeat this experiment on upwards of ninety cows, and from occasional successful cases, am obtaining fresh supplies of vaccine. The experience I have now had in several thousand cases of vaccination with this virus, and in numerous instances when exposed to small-pox contagion (some of which, as they are remarkable cases, I shall refer to) would justify me in recommending it for general use."

Page 22. "Up to the period of the experiments performed by Mr. Coely and myself, I believe, there is no authentic record of an individual in this country having succeeded in inoculating the cow with small-pox matter; but I have already shown that she may be so inoculated, and that a vesicle thus produced yields a fluid which, being transmitted to the human subject, produces all the appearances which Dr. Jenner has described as the true vaccine vesicle; thereby demonstrating

the identity of the two diseases, and that, notwithstanding the several points of dissimilarity, they are, indeed, the same—that cow-pox is still small-pox which has passed through the constitution of the cow, having lost its *infectious qualities*, but retained its *protective power*."

These quotations, taken in conjunction with the ones I sent from Mr. Coely will, I trust, incite those who are in a position so to do, to try a further set of experiments on the bovine species by means of inoculation with small-pox virus. I know very well that first-class experimenters, such as Chauveau and Sanderson, have failed to get vesicles such as those which Coely and Badoock were fortunate enough to produce; but the extreme importance of the question makes it most essential to continue these experiments much further.

I am, Sir, your obedient servant,

CHARLES R. DRESDALE

17 Woburn Place W., London,
Sept. 6, 1881.

Literature.

ANTI-VIVISECTION ESSAYS. (a)

THIS curious volume is described in a short preface as consisting of three essays, among the authors of which the sum of £200 was divided as a reward for their labours. By whom contributed, or under what circumstances there is nothing to show, but we can very sincerely congratulate the writers of these "scientific and ethical" considerations of vivisection on their good fortune in reaping such a substantial recognition of very common place, and utterly worthless, productions. It might almost be conceded forthwith that any serious examination of the oft-repeated nonsense with which the anti-vivisection bolsters up his charge against the hated man of science, is altogether unnecessary; but unhappily there are still a vast number of the general public ignorant enough to be imposed on, and influenced by the tactics of those who aim at extinguishing research in this country. Such people will always serve as a following of the determined opponents of every intellectual advance, actuated either by ignorance, prejudice, or fanaticism, they lend a ready ear to hysterical declamation of the leaders of a crusade against knowledge. We cannot, however, but regard with keen regret, the spectacle presented by members of the medical profession in voluntary alliance with the enemies of science, and working with them to attain its ultimate destruction. The only satisfaction to be found in connection with this aspect of the anti-vivisection craze, is that its medical recruits have never, so far, been such as had vindicated a claim to speak with authority on the question at issue. With one voice, those who have advanced the cause of medicine, whether by direct experiment, or by inductive reasoning, have uttered condemnation of an agitation founded on a want of a knowledge, or a deliberate concealment of the inestimable benefits conferred on man by experiments on living animals.

Dr. Macaulay occupies 82 pages of the volume before us, with an attempt to prove the inadequacy of vivisection to do ought to advance progress in medicine; and he avails himself very extensively of quotations from numerous authorities in support of his assumptions. In many cases, however, he is very unfortunate, and perhaps in no way more so than when introducing Prof. Owen (p. 12), as reproaching vivisection as a means of demonstration. Dr. Macaulay, and others like him, are too prone to urge *ex uno disce omnes*, and to leave his readers to infer erroneously from disjointed expressions. Possibly the recent full and complete vindication of the claims of vivisection by Prof. Owen will materially alter Dr. Macaulay's opinion of him as an authority on the subject.

The great mistake made by the anti-vivisection fraternity, and one that places them in a ridiculous position with all educated persons, is the assumption they make of superior knowledge on all those points which remain even to trained and competent investigators, matters of mystery. The bold effrontery with which they presume to discuss the *scientific*

(a) "Vivisection: Scientifically and Ethically Considered in Prize Essays." By Jas. Macaulay, M.A., M.D., Rev. Brewin Grant, B.A., and Abiathar Wall, M.R.C.S. 1881. Marshall, Jupp, & Co.

value of researches, the simple description of which they signally fail to comprehend, carries aggravation from the knowledge that it imposes on the credulous public it is intended to affect; but, most of all, do they err in pandering to the silly sensationalism which is the distinguishing attribute of all ignorant persons.

Dr. Macaulay is guilty of all these errors, but most striking, perhaps, is the ridiculous nature of his examination of Dr. McKendrick's illustrations of what vivisection has accomplished. We cannot help a certain amount of admiration for the courage displayed in thus attempting to ridicule the conclusions of a great physiologist on purely physiological problems; but the feeling does not extend to acceptance of the intended refutations. Dr. Macaulay, moreover, will do well if he pursues this line in future works, to learn the correct mode of spelling the names of the authorities he mentions. No doubt it necessitates a good deal of labour, but it will not be thrown away. We had intended to quote from Dr. Macaulay's essay, but space will only admit our doing so with a short passage, which, however, displays the narrow, uncomprehending character of the whole work. "In most cases, the experiments can have no bearing on medical practice. Professors Hitzig and Ferrier may anticipate wonderful results from connecting glyco-genic function of the liver, with violent injury of the brain in dogs; but as a rational practitioner would confine his treatment of diabetes to the subduing of some supposed cerebral lesion" (p. 86.) This is a fair indication of the spirit and knowledge with which Dr. Macaulay attacks experimental physiology.

Mr. Grant is ambitious. He designs his essay to be "a handbook for investigators into the scientific and moral claims, &c., &c., of vivisection." It is necessary only to say of it that its author's preface concludes in these words, descriptive of "*experimental physiology*," viz., "it promised much, and did nothing." The reader of this remarkable clergyman's disquisition on the errors of physiology will find ample confirmation in it of the well-worn adage concerning the rash intrusion of foolish persons where angels fear to tread; and a good deal of amusement will be elicited by a perusal of the clerical author's onslaught on inquiring physiologists.

Mr. Abiathar Wall, in the third essay, "scientifically and ethically" considers "painful experiments on living animals." Mr. Wall is a licentiate of the Royal College of Physicians, Ed., and M.R.C.S.E., &c. The paper is a mixture of religious invocation and silly utterances, sprinkled by professional references justified by the author's qualification probably, but it is no improvement on its fellow. The donors of the £200 will, we trust, find a wiser method of disposing of any further super-abundance of their riches.

Obituary.

DR. McCLINTOCK, of Dublin.

We deeply regret to announce the death of this eminent obstetrician and gynecologist, who expired on Saturday last after a prolonged, and, in its latter stage, very painful illness. At a comparatively early age, and well within the three score and ten of the psalmist, Dr. McClintock passed through a laborious and distinguished professional career, commencing as assistant in the Rotunda Hospital, and assistant secretary to the Cow-Pock Institution. From this he was promoted to the mastership of our great Lying-in Hospital, which he filled with remarkable ability. His term of mastership having expired, he established himself in Dublin, and assumed a leading position in his speciality, in which he enjoyed a large practice; and to the literature of which he contributed on the most extensive scale. His writings are numerous and valuable, and remain a permanent monument of keen observation, great ability, and consummate experience. He was a member of all our local professional societies, and of numerous foreign ones; and the University of Dublin conferred upon him the honorary degree of master of the obstetric art. In the midst of a busy career, and with apparently many years of health and usefulness before him, he was struck down while visiting a patient with an attack of paralysis, apparently of an embolic character. Latterly he appeared to mend, but a relapse extinguished the hopes of his many friends and well-wishers in and out of the profession. Dr. McClintock belonged to a family of very high social position in the north of Ireland,

and was the youngest of three brothers. His elder brother pre-deceased him, but the second is the well-known and distinguished Arctic explorer, Admiral Sir Leopold McClintock, K.C.B. His death will be received with regret by the Irish public.

THOMAS JAMES RAWSON, M.D., of Carlow.

A TYPICAL provincial surgeon has just passed away in the person of the above, at the advanced age of 73. Thomas James Rawson was descended of a good old stock, which had long been located in Glashealy, co. Kildare. He received his early education at Ballitore and Carlow, both of which places were noted for their seminaries in by-gone days; he obtained the license of the Royal College of Surgeons, Ireland, in the year 1830, and then proceeded to the M.D. of the Glasgow University, which degree he obtained two years afterwards. Having qualified, he determined to accept no appointment of a lower grade than a county infirmary, and a vacancy soon presented in the Carlow Institution, and after a sharp contest with a competitor who possessed considerable local influence, he was declared the successful candidate. He was for some time surgeon to the Carlow Rifles, and also to the gaol and workhouse. He was very fortunate in practice, and enjoyed the confidence of rich and poor alike for a period of well nigh half a century. He was a very able surgeon, and possessed a capital nerve, and his opinion was largely availed of in consultations in the adjoining counties. He had a commanding presence, splendid physique, and this, with the charms of a happy manner and humour, made him welcome and marked wherever he went. He possessed a capital eye, and was, in his day, one of the keenest sportsmen of the south. In politics he was a staunch conservative, and an ardent admirer of the late Earl of Beaconsfield. All the same he held his own views, though in a determined, yet in a good humoured way, and never made an enemy by so doing.

Some years ago he contracted typhus in the discharge of his workhouse duty, and about the same time carried scarlatina to a favourite daughter. The slow recovery in the first instance, and the death in the second, made an impression on him which he can scarcely have been said ever to have recovered from. Ulceration of the semi-circular canals of the ears soon afterwards set in, and he suffered considerably from tinnitus aurium and vertigo, so much so that he was obliged to resign practice, which he did in favour of his only surviving son.

The immediate cause of death was passive dilatation of the heart, and consequent dyspnoea and dropsy of the extremities. He retained his consciousness almost to the last day or two of his life, when the urine became suppressed, and he died exhausted and comatose on the 12th inst.

Queen's University in Ireland.—The following candidates having satisfied the examiners received their degrees at the October Convocation:—

DOCTOR IN MEDICINE.—*First Honour Class*: Havelock Henry Charles, Thomas Sinclair.—*Second Honour Class*: George L. Galpin, William Henry Lendrum, Francis McLoughlin, James Pinkerton, David Sempie.—*Upper Pass Division*: Warwick Long Child, Timothy Dilworth, William Walter Gibson, Patrick F. Graham, James W. B. Hodson, John Kennedy, William J. R. Knight, John S. Logan, Robert W. S. Lyons, Samuel Macaulay, William O. Maher, Edward J. Parry.—*Lower Pass Division*: Robert Anderson, Wm. G. K. Barnes, John G. Black, John Blair, Samuel Connor, James Craik, Charles Daly, John Dodd, Charles Dundee, Alexander John Fleming, David Forysth, Henry Harper, Robert Henry, Michael Jennings, John L. Jaquez, Samuel W. Johnson, Walter C. Johnson, Samuel F. Loughheed, Daniel Lynch, Edward McConnell, Thomas S. McConnell, Robert James McCormack, Joseph R. McDonnell, Bettie McFarland, Jeremiah McKenna, W. McMurray, John R. McNeill, William N. McWilliam, James Minnece, Gerald Mitchell, David T. Mouteth, William Arthur Moyuan, William Nelson, David Valentine O'Connell, Arthur O'Keefe, Robert J. O'Malley, George H. Powell, Richard M. Ralph, John Redmond, Archibald C. Robinson, R. Kutterford, David M. Saunders, William D. Sexton, James Simpson, Henry Sinclair, Robert Stuart, Edward James Holmes Sullivan, George M. Thompson, John M. Trimble, Felix O. Vinrace, Charles H. Wheeler, Charles Wiseman.

M.A.S.T.R.S. IN SURGERY.—Robert Alexander, Joseph Anderson, William G. K. Barnes, John Blair, Richard Campbell, Havelock H. H. Charles, W. Naughton Davies, Timothy Dilworth, John Dodd, Alex. Fleming, George Luck Galpin, James Geraghty, Patrick F. Graham, Robert Henry, James W. B. Hodson, Edward Horan, John Kennedy, William Henry Lendrum, J. Smyth Logan, Daniel Lynch, R. W. Steele Lyons, Samuel Macaulay, Robert McCormack, Jeremiah McKenna, Wahab McMurray, John Robinson McNeill, W. O. Maher, James Minnece, Gerald Mitchell, David Taylor Mouteth, William A. Moyuan, James Mullin, John F. J. Mullin, William Nelson, James A. Oakesott, Arthur O'Keefe, David J. O'Malley, James Pinkerton, George H. Powell, David M. Saunders, David Sempie, Henry Sinclair, Thomas Sinclair, William Smyth, Robert Stewart, Jeremiah Sugree, Edward J.

Homes Sullivan, George M. Thompson, John M. Trimble, Felix Coulson Vinrace, Charles H. Wheeler, James B. White, James E. White.

DIPLOMA IN MIDWIFERY.—J. Greer Black, John Blair, Havelock, H. B. Charles, Warwick L. Child, Samuel Connor, Charles Daly, W. Naunton Davies, Timothy Dfiworth, Patrick F. Graham, John Kennedy, William H. Lendrum, J. Smythe Logan, David Lynch, Robert J. McCormack, Jeremiah McKennah, W. Odillo Maher, James Minnieor, James Mullin, James A. Oakshott, David V. O'Connell, Arthur O'Keefe, James Pinkerton, George H. Powell, Richard M. Ralph, John Redmond, David M. Saunders, David Sempie, Henry Stielar, Edward J. Holmes Sullivan, David Taylor, George Matthew Thompson, James B. White, James E. White.

King and Queen's College of Physicians.—At the October Examinations the following obtained the Licence in Medicine and Midwifery of the College:—

MEDICINE.—George Abbott, Francis George Bonyage, Mark Andrew Brennan, Patrick Joseph Dempsey, Walter William Stockton Jones, Charles Louis Lumley, Francis Edward McFarland, Vincent John Magrane, Lyster Andrew Noian, Daniel M. O'Connor, Charles Parsons, John Alexander Cairns Penny, John Tuthill.

MIDWIFERY.—George Abbott, Francis George Bonyage, Walter William Stockton Jones, Charles Louis Lumley, Vincent John Magrane, Lyster Andrew Noian, Charles Parsons, John Alexander Cairns Penny, John Tuthill.

The following Licentiates have been admitted Members:—

James Chalmers Cameron (George Cochet Chevaye (Surgeon-Major, Indian Army), George Nield Cooper, Thomas O'Dwyer Russell, Richard Baker Smith, George Westby.

NOTICES TO CORRESPONDENTS.

MR. SERBE (Leipzig).—The Directory in question contains all the hospitals, infirmaries, dispensaries, and medical institutions in the country.

MR. SPARKES (Kensington).—The subject selected for the next Astley Cooper Triennial Prize is "The Pathology and Pathological Relations of the Disease known as Osteo-Arthritis, or Chronic Rheumatic Arthritis." There is yet more than a year before essays need be sent in. Further particulars will be found on reference to our columns, Dec. 1, 1890, page xiii. The value of the prize is £300.

MEDAR BALVANTRAS VINCECK SHASTREE (Bombay).—The author referred to in your letter has been dead some years.

QUACKERY AS AN INVESTMENT.—A correspondent sends us a clipping from a local paper in which is evidenced—a fact but too well known to the regular practitioner—the enormous gains made by quacks, as contradistinguished to legitimate practice. A few days ago an estate was put up for auction and the quack outbidding all others, purchased the property for £10,000. The same quack is understood to be paying income-tax on £4,000 a year; not a happy illustration that "honesty is the best policy."

E. S. (Portlengone).—A student who has matriculated in the Q.U.I. will not be required to pass the matriculation examination of the Royal Irish University, but must pass the First Examination in Arts at the end of his first year.

MR. SIDNEY DAVIES.—Cases received with thanks. They are put in hand for early insertion.

MR. CHIPPENDALE will find all the information he desires in our "Students' Number," Sept. 21st, and in the subsequent number (Sept. 28th) containing chapter on "Student's Books and Reading."

S. S., MEDICAL OFFICER.—(1) When it is desired to build a dispensary residence the guardians must set forth in memorial to the L.G.B. their propositions and their reasons, and the L.G.B., before giving consent, must specially inquire. The medical officer should, of course, be consulted by the guardians, as he is specially interested, but it is not legally necessary that his opinion should be asked. He can, of course, with great force make representations to the L.G.B., who will certainly not oblige him to pay for, and live in, an unsuitable house. (2) A licentiate in midwifery is not entitled to hold office as medical attendant on the constabulary, or in any other public capacity, and, if he is so acting, an appeal should be made to the Irish Medical Association.

MR. BISSENDEN is thanked for his kindly interest.

DR. J. A. R.—The subject is scarcely ripe for discussion; information is being sought in various channels so that it may be treated exhaustively, and we trust with a useful result.

A LAY READER.—We do not prescribe in these columns; yours is a case which any qualified medical man could treat successfully.

DR. D. asks: (1) Is there any rule as to the number of years a dispensary medical officer must serve before he could be qualified for the appointment of Local Government Inspector, or how the appointments are made? (2) What is my remedy, as a dispensary hack, if I can get red tickets cancelled. Can I legally recover a fee from the issuer of the ticket?

[1. There is no special qualification for a Poor-law Inspectorship. A dispensary doctor has no peculiar claim, nor will any period of service give him a title to the appointment. 2. Fees can be recovered from the issuer of a cancelled ticket if it can be shown that he has negligently or wilfully issued a ticket to an undeserving person. There would be no difficulty about proving this if—as is usual—the ticket were not filed up by the issuer but only signed by him. The recipient may also be sued if it can be shown that he obtained the ticket by false pretence.—ED.]

DR. W. H. PEARSE.—Letter received as we were at press, shall appear in our next.

MR. F. A. C. H.—Probably in our next.

MR. H. THOMAS.—We know of no institution in the United Kingdom answering exactly to the requirements of your letter. Write to the Secretary of the National Hospital for Epilepsy and Paralysis, Queen Square, London. Possibly your case might be considered.

DR. M. P. J.—Many thanks.

THE SOCIETIES.

HUNTERIAN SOCIETY.—This (Wednesday) evening, at 8 Mr. Stevens will show a Tumour of the Brain.—Mr. T. E. Adams, "On Injuries to the Arteries of the Lower Extremities."

ABERNETHIAN SOCIETY (St. Bartholomew's Hospital).—Thursday, Oct. 27, at 8 p.m., Mr. Bowly, "On the Treatment of Wounds."

QUEEN'S MICROSCOPICAL CLUB.—Friday, Oct. 28, at 8 p.m., Ordinary Meeting.

CLINICAL SOCIETY OF LONDON.—Friday, Oct. 28, at 8.30 p.m., Mr. T. C. Dent, "On a Case of Strangulated Hernia (Littré's) or Partial Enterocoele."—Dr. Churton (Leeds), "On a Case of Cholesterolin-containing Fluid in the Pleura."—Mr. Keover, "On a Case of Stricture of the Pharynx and Oesophagus, with special reference to Gastrostomy and Oesophagotomy."—Dr. Stephen Mackenzie, "On a Case of excessively High Temperature."

Vacancies.

Bath Eastern Dispensary.—Resident Medical Officer. Salary, £150. Applications to the Hon. Secretary, 10 Beaufort Buildings, by Nov. 1.

Dental Hospital, London.—Assistant Surgeon. Full information of the Hon. Sec. at the Hospital, Leicester Square.

Drogheda Union, Termonteen Dispensary.—Medical Officer. Salary, £110, and £80 as Medical Officer of Health. Election, Nov. 8.

Middlesex Hospital.—Surgical Registrar. Full information of the Secretary Superintendent.

Monmouth Union (Wales).—District Medical Officer. Salary, £40, with the usual extra fees. Applications to the Clerk of the Union by Nov. 4.

South Devon Hospital.—House Surgeon. Salary, £80, with board. Applications to the Hon. Sec. at the Hospital, Plymouth, by Nov. 7.

Appointments.

FREEMAN, H. W., L.R.C.P. Lond., M.R.C.S.E., Surgeon to the Royal United Hospital, Bath.

FRY, J. B., L.R.C.P. Lond., M.R.C.S. Eng., Medical Officer of Health to the Swindon Urban and Rural Sanitary Districts.

HALBY, W. H., L.R.C.P. Ed., L.R.S. Ed., Medical Officer for the Wakefield District of the Wakefield Union.

HAMILTON, D. J., M.B., F.R.C.S. Ed., Pathologist to the Royal Hospital for Sick Children, Edinburgh.

HEWITSON, J., M.B., C.M. Ed., House Surgeon to the Royal Maternity and Simpson Memorial Hospital.

HOAR, C., M.B., C.M. Aber., Medical Officer for the Fifth District of the Battle Union.

KELLY, H. J., M.D. St. And., M.R.C.S., Medical Officer for the Castle Bromwich District of the Aston Union.

KIDD, F. H., M.B., C.M. Ed., House Surgeon to Great Yarmouth Hospital.

MURPHY, J. B.A., M.D., Consulting Surgeon to the Monkwearmouth and Southwick Dispensary.

Ogilvie, Dr. G., B.Sc., M.B., Physician to the Hospital for Epilepsy and Paralysis, Portland Terrace, London.

OZANNE, F. N., M.R.C.S., House Surgeon to the Weston-super-Mare Hospital and Dispensary.

Births.

CORFIELD.—Oct. 19, at 10 Bolton Row, Mayfair, W., the wife of Professor Corfield, M.D. Oxon, of a daughter.

FAULKNER.—Oct. 27, at 8 Coleridge Road, Finsbury Park, the wife of J. Faulkner, M.R.C.S., of a son.

MANDERS.—Oct. 17, at Yorktown, Surrey, the wife of Horace Manders, F.R.C.S., of a son.

STRITCH.—Oct. 10, at 24 St. Kevin's Parade, Dublin, the wife of George Andrew Stritch, M.D., Charlestown, co. Mayo, of a son.

Deaths.

BARNARDO.—Oct. 17, at Birkdale Park, Southport, Isabelle Florence, the beloved wife of Dr. F. A. Ernest Barnardo, aged 24.

BROSTER.—Oct. 20, at the Naval Hospital, Haslar, Edward R. Broster, Fleet Surgeon R.N.

COWAN.—Oct. 19, at Holles Street, Cavendish Square, London, Jessie, widow of J. Moffat Cowan, M.D., of Edinburgh.

DAY.—Oct. 13, at Hambrook Lodge, Ultracombe, Edwin Day, M.R.C.S., late of Court House, Hambrook.

DOMVILLE.—Oct. 21, at his residence, the Royal Hospital, Haslar, Wm. Thos. Domville, C.B., M.D., Inspector-General of Hospitals and Fleets, Honorary Surgeon to H.M. the Queen, aged 57.

DREW.—Oct. 10, at his residence, Clogher Head, John Drew, M.D.

GWILLIM.—Oct. 14 at the residence of his son-in-law, at Burton-on-Trent, William Gwillim, M.R.C.S., aged 89.

MAWHINNY.—Oct. 20, at his residence, 128 Rathgar Road, Dublin, suddenly, Thomas Mawhinny, M.D., son of the late Dr. Mawhinny, Belfast.

MCCLEINTOCK.—Oct. 21, of heart disease, Alfred Henry McCleintock, M.D., LL.D., ex-President of the Royal College of Surgeons, Ireland, second son of the late Henry McCleintock, of Dundalk, on his 60th birthday.

RAWSON.—Oct. 12, at Barrow-Ville, Carlou, Thomas James Rawson, M.D., aged 73.

SMITH.—Oct. 8, at Sheffield, Charles Smith, B.A. Cantab., M.D. Edin., aged 87.

WALSH.—Sept. 13, at Thayetmeyo, British Burmah, Thos. Pakenham Walsh, Surgeon A.M.D., late of Athlone, aged 24.

VALUE OF RECENT INVESTIGATIONS IN THE TREATMENT OF DISEASE. (a)

By **MATHEW CHARTERIS, M.D., F.R.C.S. Ed.**

Professor of Materia Medica and Therapeutics in the University of Glasgow; Physician to, and Lecturer on Clinical Medicine at the Glasgow Royal Infirmary.

In consequence of the interest taken by the public in medical matters, the profession, said Professor Charteris, is now every day asked—"Have you utilised recent investigations in treating the diseases of every day life?" In endeavouring to answer this question he showed that disease, in so far as it generally attacks mankind, may be fairly and legitimately divided into two great classes:—1. Acute zymotic diseases; 2. general diseases and diseases of individual systems. The diseases of the former class are intimately connected with the investigations of the present day. They have been known certainly in all time, but until lately they have been but little understood. They were huddled together promiscuously. Their origin seemed mysterious. They were distinguished simply by their eruptions, their course, and their fatality, and such a classification, and such a conception, frustrated their sanitary prevention, and often rendered nugatory all care, and skill, and hope. We live now in a different time, and we have stripped off much of the mystery which surrounded their course. We say that they are dependent on particular lowly organisms, that these organisms entering into the system, produce and reproduce themselves in numbers infinite and possibly definite in form. True, we cannot catch the individual germs in which these diseases originate. We cannot place them on the microscopic slide and say, "Lo! there the germ, there the embryo of the race's fatal enemies." But that they do exist no one attempts to deny, for it is the only logical conclusion to be drawn from the history of

(a) A Lecture delivered at the opening of the Winter Session of the University of Glasgow on October 25th.

the maladies. Their etiology, based on definite facts, is now known beyond the professional pale, and has become the household information of every well-educated and intelligent man. The knowledge is also imparted that, while sanitary science has done much to destroy their virulence and impair their epidemic type, it cannot and never will be able to prevent their quasi-epidemic or sporadic character. The further question also is asked—"How may these germs be destroyed when they have gained an entrance into the system?" The answer might be made that diseases so engendered tend to exhaust themselves. Nature rebels against such unbidden and unwelcome guests, and we aid her efforts by careful hygienic surroundings and judicious diet. We attend, as Sir W. Jenner happily expressed it, to the little things connected with the sick bed, and we await with confidence the result: we trust to Nature.

The question of general fever was then discussed, and the means by which it may be lessened, either by the administration of potent drugs whereby the life of the fever-producing germs is destroyed, or by the direct withdrawal of heat by baths at a regulated low temperature. The action of quinine in malarial fever, and of salicin and the salicylates in rheumatic fever, was then noticed as illustrating the advance of therapeutics in late years. Such answers, then, may be given by the profession to the public about the progress of art in diseases which come home with startling force to peoples and communities. They show the affinities of the rightly-applied medicines and therapeutic methods of the present day. They indicate the principles on which they are given, and these principles are based on well-defined scientific lines. The idea is communistic, for it has the imprimatur of men of every land. The progress is recent, but it is great, and it bids us hope for more. The field is vast, but the labourers are many, and judging from what has been so rapidly accomplished, we may confidently anticipate with Binz, of Bonn, "that pharmacology, interpreting the etiology of infectious diseases, may yet discover specific antidotes for each" or, with Huxley, state "that it will become impossible to introduce into the economy a molecular mechanism which, like a very cunningly contrived torpedo, shall find its way to some particular group of living elements and cause an explosion among them,

leaving the rest untouched." With regard to diseases not dependent on germ life, the position of the profession is different. On the investigation of remedy *versus* disease—the crucial point on which the question turns—this may be considered as generally conceded, that every remedy must be adjudicated upon in connection with the natural march of the malady it is given to cope with. If this be slight and harmless, if nothing will go wrong, if ordinary care and common sense be exercised, then we cannot attribute extraordinary merit to any drug selected and prescribed. A recital of drug cures in circumstances like these, is unnecessary, when a candid explanation of, and intelligent sympathy with, the patient's state is the best, most truthful, and in the long run most paying recipe. But in dealing with other maladies not so trivial in their nature, nor so innocuous in their course, which are met with in practice every day, and where life, it may be, hangs in the balance, the physician is false to the traditions of his art who can only confess his incapacity, who knows nothing and suggests nothing. To the sick man this conduct is death. To the friends and to the public it is cool and heartless cynicism. To the impartial critic it means "medical suicide," for he sees that if the policy of expectancy is carried to its legitimate conclusion there is a sapping of the foundations of therapeutic faith. There is a lowering of the public interest in scientific inquiry. There is no use in "having doctors at all." Such a doctrine is properly fatal to the position of the profession in the eyes of the public. It is necessarily false to the best interests of the profession, and besides it is not in accordance with present facts. The acquaintance with pharmacology is based on intelligent premises. We endeavour to test the actions of medicines by the methods of research inaugurated by Morgagni, and followed up by his successors in the present day. It is needless here to state what these methods are. It is sufficient to aver that in the eyes of men most competent to judge they are excellent. They have led to a most correct appreciation of the value of individual remedies, for they have determined how each drug acts in health in relative parts of the body; what it specially affects, what it leaves untouched.

Its exactitude so far cannot be questioned, and the knowledge so acquired is applied to special forms of disease with a confidence we had not before. Thus it has narrowed a field of particular drugs. It has loosened the hold of empirical remedies. It has dismissed much of the polypharmacy which overshadowed vague and unseemly mixtures, and obliterated the triumphs apt to be assumed by incongruous ingredients. It makes prescriptions simpler and less fortuitous in their scope. Therapeutics takes up a position which is critical but not antagonistic to its ally. It acknowledges that physiology is not medicine, and that we cannot trust to it alone; for we must recollect that the most significant testing-ground for medical agents is the hospital ward and actual practice. It states that the action of a medicine may be accurately described so far as it affects a healthy human being or animal. Its influence on digestion, on the circulation, on the respiration, and the nervous system may then be unquestioned. Looking at what has already been accomplished by the cordial working of these two methods, I know I can truly say that of no other disease, unless pronounced hopeless by its nature, which could not be benefited by medical aid, meaning by this not the nurse's attention, but the physician's skill. When we contrast the bleakness of the prospect which stretched before anyone who a hundred years ago surveyed the therapeutic future, the triumphs of vaccination against small-pox, of chloroform in painful surgical operations, and of the alkaline bromides in epilepsy, these and others to which I might allude, are undoubted evidences of solid progress.

We are recipients of a trust, and he who is faithful to this will cherish it without seeking to deface the landmarks on which it rests. The cardinal point of our profession has ever been the giving of medicines in agree-

gates sufficient to produce physiological action, for without this there can never be therapeutic gain. If we keep this steadily in view, we find in the whole history of medicine no encouragement given to us by the career of those schismatics who have left our ranks. By what they afterwards accomplished they have done nothing. They can do nothing, for their infinitesimal quantities are contrary to every principle which science reveals and practice accepts. In every case where medicine has left its mark on disease no feeble policy has guided the hand. It has ever been strong, and vigorous, and active. To future graduates of medicine I would say, carry the hope of progress with you into the work of your after life, and you will feel yourselves loyal sons of men whose names are dear to every student's heart. Deal gently with the weaknesses of the old masters, as revealed in their writings, and with no scornful hand lay bare their errors in judgment and discrepancies in treatment. They failed in much, but they achieved much, and in the dim and shadowy past in which they lived, remember that their lights were feeble as compared with yours. Seek not to destroy the belief in the *Ars medicandi* which they helped to rear with great labour, and which they nourished with faithful care. "The proper study of mankind is man," and man sends for you to study him, not in the glow of his physical strength and pride of intellectual might, but in the day of his danger and hour of bodily weakness. He does so in the hope that you may do him good, and not that you may regard him simply as an instructive and interesting case of physical or mental decay. Remember this in the time of your pupilage, and when you have passed from the threshold of this University into the busy pursuits of your after-life, and so reflecting and so acting, your student days will be true and earnest, and your future career sustained by the rich reward of merited success. Place before you no other standard, however seductive the prospect, than the desire to diminish the suffering and extend the term of the troubled years of those who have trusted themselves or theirs to your honour or your skill.

REMARKS ON DISSOLUTION OF THE NERVOUS SYSTEM, AS EXEMPLIFIED BY CERTAIN POST-EPILEPTIC CONDITIONS.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P., F.R.S.,
Physician to the London Hospital, and to the National Hospital for the Epileptic and Paralysed.

(Continued from page 70.)

SECTION XII.—The Nature of the Positive Elements (continued) Anatomically Considered.

ANATOMICALLY considered, the negative elements—to return to them for a moment—are (Section IX.) losses of adjustments of the organism, as a whole, to the environment in the order, according to the "depth" of the dissolution, from the most special and complex of them towards the most general and simple. Correspondingly the positive elements are anatomically considered *retentions*, and often over-developments, of more general and simple adjustments of the organism as a whole (a) to the environment

(a) It occurs to me as possible that the expression, "adjustments of the organism as a whole," may be taken to mean that all parts of the body, arms, legs, eyes, mouth, &c., are acting at once "upon the environment." This is as much a misunderstanding as if it were inferred from a common use of the term environment in the above, that I meant that every part of the patient's universe was being acted on. During a voluntary action (say that I pick up a pin) there is a movement which is an outcome of—is the then *termination* of—activities, however slight most of them may be, of the whole organism; and so there is whilst I am thinking of doing it. In *this* sense "the organism as a whole" is engaged during picking up the pin. Otherwise the pronoun "I" in the proposition, "I pick up a pin," is meaningless. The "I" stands in that context for what is physically the organism represented as a whole, and for what psychically is the person subjectively. And if "I" is meaningless,

than those in health, and still in the order, according to the depth of the dissolution, from the less special and complex towards most general and simple adjustments—down, in deep coma, to adjustments, some of which, as the circulatory, appear to be of parts of the organism one to another. (All adjustments are, strictly speaking, of parts of the organism to one another.)

The expression, "towards more general adjustments," requires some qualification which will be made later when we speak of Partial Dissolutions.

SECTION XIII.—*The Nature of the Positive Elements (continue I).*—*The Positive Element cannot be said to be always Abnormal from Over-activity.*

In the third sentence of Section X. I said of the positive condition that it was "often abnormal" by over-activity, because I cannot prove that the nervous arrangements, lower than those exhausted, are in all cases—as I really suppose them to be—over-active. They may perhaps be left in their ordinary state of activity or readiness for activity. I will now consider the positive condition, and partly clinically, with the hope of dissipating the vagueness of "most often;" in other words, I shall try to show why in some cases the positive condition is not, or is but slightly, hyperpositive.

We have not only to consider (taking here for illustration the second post-epileptic condition, that of actions) the particular things done, and the degree of speciality and complexity of the actions, but whether they are slow and unfrequent or quick and frequent. (a) Whether, that is to say, they are the outcome of a normal, or of a nearly normal, condition, or of a highly-raised activity of the lower nervous arrangements. We speak of the "rate of the actions." (b) They differ in different cases vastly in this way. There are at one extreme cases in which the post-epileptic patient's conduct is, so much as there is of it, almost normal in rate. The patient cannot be declared to be too busy or over-active. Thus, a child after a slight epileptic seizure, may do nothing, but may do simple things when told, such as shutting a door. Then at the other extreme there are cases of furious post-epileptic mania, in which the actions are very quick and frequent. The post-epileptic maniac

"pick up a pin" is so too. This part of the proposition stands for what again is physically the organism represented as a whole, and for what is psychically the person objectively. A fault of popular psychology is that it does not give full and true value to pronouns. It is for this reason that it is so tautological. Instead of saying, "He has a sensation," the common expression is, "He is conscious of a sensation," as if "he" were not a pronoun standing for a person—for one who is conscious. The duplication, subjective and objective, is sufficiently expressed by the simpler proposition; it means a sensation in relation to all our other mental states, and also a sensation referred to this or that part of us. To say the organism, as a whole, is specially adjusted to the environment—adjusted to specialities in the environment—is to speak of the physical side of what is psychically expressed in saying, "He does this particular thing." During a voluntary movement there are, at any rate, activities of some of the highest nervous arrangements—of some of those, that is to say, each of which represents the whole organism—the highest nervous arrangements are the whole organism, so to speak, potentially."

(a) The meaning of some words in the text may be made clearer by quoting what Sanderson tells us authors say of some characters of the pulse:—"1. As regards the number of pulsations per minute, the pulse is said to be frequent or infrequent—*pulsus frequens, pulsus rarus*. 2. As regards the time which seems to be occupied by each beat, not including the interval between it and its successor, the pulse is said to be slow or quick—*pulsus celer, pulsus tardus*."—*Handbook of the Sphygmograph*, p. 13.

(b) A man, after a slight epileptic fit, mixes cocoa in a dirty gillipot used for the cat's food, with a mustard spoon, which he must have gone to the cupboard to obtain (he remembered nothing of these doings on recovery). This action was a special and complex one. (It was in accord with what was arranged before the fit set in.) A man after a fit lies rapidly sprawling, kicking and shouting, on the floor. This is a simple and general action. Besides recognising the differences in speciality and complexity by these two post-epileptic actions, we should note the "rate" of the doings. Those of the latter patient are at a greater rate

is the most furious of all maniacs; the fury implies great "rate" of his actions. The hypothesis I have formulated is that the degree of activity of the lower nervous arrangements—and consequently the rate of the actions—varies directly, not according to the "depth" of the dissolution, but according to the time in which the dissolution "shallow" or "deep" is effected—according to the time in which "control is removed."

The "deeper" the dissolution the more general the actions; the more rapidly the dissolution is effected the greater is the rate of the actions. Some seeming, but not real, qualifications have to be made on these two statements.

The full complexity of the question raised in the preceding paragraph has not been laid out; it is a very complex one. By anticipation I will now state, and yet very briefly, an hypothesis as to differences in the effects of epileptic discharges of different severities, with special regard to the "depth," degree, and duration of the post-paroxysmal exhaustion effected by them; and consequently with regard to the generality, rate, and duration of the permitted actions. We must begin with the epileptic paroxysm, although what we have directly to deal with in this section is the post-paroxysmal condition, the condition remaining when the epileptic discharge answering to the paroxysm is over.

In Section VI. I said that the expression "severe" applied to epileptic paroxysms is vague; and so then, of course, is that expression applied to nervous discharges which produce the paroxysm. We have to consider not only the quantity of energy liberated, but the rate of its liberation. My belief is that a more rapid liberation of energy gives rise to nerve currents of greater force—that is, to currents capable of overcoming lines of greater resistance—than does a slower liberation of an equal quantity of energy. If so, then from the more rapid liberation there will be wider spreading of currents, and consequently convulsion of greater range. The highly unstable cells of the "discharging lesion" being a "fulminate," when discharged overcome—that is, discharge—normally unstable—that is, healthy—cells, collateral and lower. There is a primary discharge (of cells we likened to a fulminate), and then a secondary discharge of healthy cells physiologically connected with those primarily discharging. The more rapid the primary discharge of the "fulminate," the more of the normally unstable cells are overcome—the wider the secondary discharge. In other words, from a "severer" discharge—meaning one giving rise to currents of greater force—the spasm is greater in Compound degree than that from a "slighter" discharge. I mean that there is not simply more spasm, but greater range of spasm also. (See later on Compound Degrees of Paralysis.) There is, I believe, less spasm locally, but there is more altogether.

Nothing said in this Section implies the belief that nerve impulses travel at different rates. A rapid discharge means many impulses travelling in a short time—a great "quantity of motion" in a short time. A quantity of energy liberated in a short time gives rise to currents of greater force than does an equal quantity liberated in a longer time. Thus the terms "force" and "energy" are not used convertibly. This must be borne in mind when the term, "rapid discharge," or "rapid liberation of energy," is employed.

The expression, "lines of resistance," is used. What a nervous discharge can do depends not only on the force of the current developed, but also on the resistance met with. In the same way we have not only to think of nerve fibres as connecting centres, but as keeping them apart—the fibres resist as well as conduct. (a) Neglecting for the present nerve fibres, nerve cells are not only "energy reservoirs," but parts offering resistance. Thus the middle cerebral motor centres (I mean Hitzig and Ferrier's

(a) Sydney Ringer is the first physician who, so far as I know, has pointed out the importance of recognising resistance offered by nervous elements.

centres) stand betwixt the highest motor centres and the spinal (and higher homologous) motor centres. The primary discharges in the cases we speak of ("epilepsy proper") are of parts of the highest centres. It is only when the resisting cells of these middle centres are overcome that their energy is added on to that of the primary discharge—to that of the discharge of what we called the fulminate; ultimately the lowest motor centres are overcome, the muscles are gained and put in spasm. Observe there is a great multiplication of energy as the process "goes down." Of course currents spread in the highest centres also, when some part of these centres is discharged and they spread according to the different resistances offered. One difference betwixt *le petit mal* and *le grand mal* is, I suppose, that in the former the lower cerebral centres are not overcome (except for some cells representing some small muscles), and that in the latter they are. When the lower centres are not overcome, the currents, I suppose, spread more in the highest centres; hence in some cases of *le petit mal* there is complete loss of consciousness for a short time, with but little peripheral effect. (a)

Thus we may understand more clearly that a more sudden and rapid discharge leads to convulsion of greater range than does a deliberate and slow discharge. The currents developed from a rapid discharge spread in more ways, not only in lines of least resistance, but in lines of greater resistance.

Now for the hypothesis as to the condition after the discharges. First, for the negative element of the after conditions. There is exhaustion where the discharge or the current developed "has been." After a rapid discharge the exhaustion of nervous elements has been more suddenly established, it is more widespread, it is slighter in degree, and is more transitory than after a slower liberation of an equal quantity of energy. If so, the difference betwixt the exhaustion produced by the two is a difference in compound degree. We have on the one hand (1) suddenly established; (2) widespread ("deep"); (3) slight; and (4) transitory exhaustion, against, on the other (1) slowly established; (2) limited ("shallow"); (3) more nearly complete and (4) lengthy exhaustion.

Now for the positive condition "under," so to speak the negative condition; that is, the condition of the nervous arrangements next lower than those exhausted. We mean physiologically lower. I think that in the former case the positive condition is more hyperpositive (control being more rapidly removed), the outcome of it is in actions of greater rate, in more general actions (the dissolution being deeper), and that it is more transitory, the exhaustion being slighter. In the latter case I suppose that the positive condition is more nearly normal; that the actions are more nearly normal in rate, less general in character; that they continue for a longer time.

SECTION XIV.—*The Nature of the Positive Element (continued).—Its Psychological Side.*

In Section IX. we spoke, when considering the negative elements, both of the negative psychological state, and of the negative physical state corresponding to it. We should attempt a similar distinction in the positive elements.

It is manifest that in the positive element of the first degree there is a psychical state with a correlative nervous

(a) The reader will note that we speak of three motor centres of different grades of evolution. 1. Highest (the motor substrata of consciousness, or of most vivid consciousness). 2. Lower (Hitzig and Ferrier's centres). 3. Lowest (Spinal and higher homologous motor nuclei). In this we do not follow what I may call the geographical division into spinal cord, medulla oblongata, pons varolii, &c. (As already mentioned, the "cerebellar system" is ignored in this work.) The highest and lower motor centres, if not the lowest centres, are, I consider, only chiefly motor. Later on I shall speak of three chiefly sensory centres. I wish now to mention explicitly that this double order of centres is not supposed to correspond to our three degrees of post-epileptic conditions. In the first and second degrees, at any rate, the highest centres are engaged; in the second both the highest and the lower and lowest. Only some of the nervous arrangements of the highest centres are supposed to be exhausted in any of the three degrees.

state; the patient on recovery remembers his "dream," knows at least that he had some mental state.

As to the positive element in the second degree (of actions) there is the difficulty we have several times mentioned (Sections v. and VIII.) We say that the patient in this degree has "loss" of consciousness. On the arbitrary use of this term we commented in Section v.; for our present purpose it is enough to say that the patient, on restoration, remembers nothing of what he did. Yet this unconscious patient acts elaborately, and his actions are sometimes purposive-seeming. Whether there is a psychical state during, and corresponding to, such actions, is a question on which there will be differences of opinion. (See Section VIII.) That there is activity of some of the highest nervous arrangements, however many of the others are *hors de combat*, is, I think, not doubtful.

As to there being any sort of consciousness, however rudimentary, attending, I mean correlative with, the nervous activities, the outcome of which are the "vital" operations in the third degree, there will be but little difference of opinion. I express no opinion. But that either some mental state, or activities of some of the highest nervous arrangements, or some kind of condition persists in a few cases during coma, is, I think, probable (Section III., footnote a); for an operation, interrupted by the comatizing lesion, is sometimes re-begun on recovery, or, perhaps I should say, on partial recovery; indeed, it may go on in a fashion during part of the coma. (a)

(To be continued).

A NOTE ON VACCINATION AND RE-VACCINATION.

By WILLIAM BERRY, M.R.C.S. Eng., L.R.C.P. & S. Ed.,
Hon. Surgeon Royal Albert Edward Infirmary, Wigan.

INSUSCEPTIBILITY of vaccination is not much believed in either by the vaccination inspectors or public vaccinators, and during an experience of eight years in private practice, I can bear out this belief. I have seldom been called upon to certify that a child is not susceptible after having been vaccinated three times as required by the regulations for such a certificate, and my experience of two cases recently would certainly lead me to think that such a certificate should rarely be given.

My first instance is that of a child, seven months old, allowed by the parents, who objected to vaccination, to be delayed till compelled by the vaccination officer to submit the child for vaccination. I was requested to obtain calf lymph which I did, and vaccinated the baby the day I received a well charged point. I took good care to rub the lymph well into the scarifications, and on the eighth day, to my chagrin, nothing could be seen to mark the seat of operation; I now obtained a second point, and this was also unsuccessful. I was now asked to sign the certificate of insusceptibility, but objected, and left them to receive another request from the vaccination officer. In a few weeks, therefore, I was again requested to perform the operation for the third and last time. My faith being shaken in "pure calf lymph" I took a tube of fresh human lymph, and was rewarded on the eighth day by a fine crop of vesicles. The father of the child assuring me I had not used calf lymph this time.

My second example is that of a fine healthy babe, which was first vaccinated from a tube of lymph I had had from the National Vaccine Institution twelve months before, as I was anxious to begin a fresh stock of lymph, this failed. A second time I used a tube of lymph got at the same time as the last, and from the same institution, this also failed. The third time I wrote and got from the Vaccine Institution another supply, one tube was sent me

(a) Perhaps the term coma may be thought illegitimate when applied to cases where there are any sort of actions beyond "vital" movements, if the latter are to be called actions. But some elaborate actions, such as twirling a moustache, may go on in a man who is, for the rest, fatally comatose.

this also failed. I wrote and asked for another tube, and vaccinated for the *fourth* time, this also failed. I now got a tube of calf lymph from an agency in London, and this failed also. This being the *fifth* time I had performed the operation unsuccessfully. Not being satisfied I vaccinated for the *sixth* time from the fine vesicles of a healthy child, and was rewarded on the eighth day with three very fine vesicles.

These two cases, especially the last, are to my mind almost proof against the non-susceptibility of vaccination, and for the future I shall be exceedingly doubtful, if ever called upon to certify after a third vaccination. It is remarkable also that this is the first time, that lymph supplied from the National Vaccine establishment, has failed.

With regard to re-vaccinations, at the commencement of this year I had a remarkable run of success, and ample proof that re-vaccination should be resorted to oftener than it is, and more especially, if we are threatened with an epidemic of small-pox.

As medical officer to a college of pupil teachers, I re-vaccinated 29 pupil teachers, varying in age from 13 to 21 years, many of whom had very good marks of primary vaccination—23 were successful, or 79·3 per cent. I may here remark that three-fourths of them had vesicles equal to those of primary vaccination. I next vaccinated 12 boarders, ranging in age from 4 to 12 years, out of these 11 were successful, or 91·8 per cent. Fifteen mistresses and 2 assistants were next vaccinated, these varied in age from 30 to 55, some of whom had been re-vaccinated a few years previously—6 were successful, or 35·3 per cent. I re-vaccinated 10 private patients, and all were successful.

Therefore, out of a total of 68 re-vaccinations 50 were successful, or 73·5 per cent. In my first lot of 58 cases I had to make the lymph go as far as possible, one tube having to serve for nearly half a dozen people. I used a little cold water for dilution.

Many of the cases had very large vesicles, with an inflamed areola, which, however soon subsided after the use of a bread poultice for a day or two.

STIMULANTS IN WORKHOUSES.—III.

THE OFFICERS' BEER RATION.

By NORMAN KERR, M.D., F.L.S., London.

An inspection of the Parliamentary Return of 1871 brings to light the honourable position occupied by the officers of the union of St. Anstell, Cornwall, who are stated to be all total abstainers. At Eton, though the master was allowed ale, we are told he did not drink any.

In some unions, the official and healthy inmate proportion of the whole alcoholic expenditure is very large. The West Derby Union in the Special Report of 1871 inform us that, while the cost of alcoholic liquors for the sick was no more than £500, the corresponding outlay for officers, and inmates not under medical treatment, was as much £390.

An analysis of the Parliamentary Return reveals the fact that there was no expense at all for liquor to officers in the English counties of Northumberland, with twelve unions, and Westmoreland, with three unions. Neither was there in the Welsh counties of Anglesey, with two unions; Cardigan, with five; Carmarthen, with five; Carnarvon, with four; Denbigh, with three; Merioneth, with four; Pembroke, with three; and Radnor, with one workhouse.

In several counties, there was only a minority of the unions expending money on beer for the official staff. In the county of Cornwall there was but one union of the thirteen so doing; in Cumberland one union of the nine; in Durham there were three of the fifteen; in the West Riding of Yorkshire four of the ten; and in the North Riding three of the sixteen.

In England there were 171 unions which spent nothing for beer or other liquor for the officials, against 413 which gave the beer ration. In one union the schoolmistress and nurse had half a bottle of wine daily instead of beer.

Of the 171 providing no beer, a number gave a money allowance instead. The following are the particulars of such from the Parliamentary Return:—A money allowance, of which the amount was not specified, was given in the unions of Forehoe, Henstead, Loddon and Clavering, Mitford and Launditch, and Meriden; £2 a year was the amount of the grant at Chester and Williton; 1½d. a day at Yeovil; and 2d. a day at Calne. It is 1s. a week at Newent, Liverpool, Barrow-upon-Soar, Spilsby, Melton Mowbray, Radford, Thame, Malmesbury, and Rotherham. £3 a year was allowed at Ellesmere; and 1s. 9d. at Saffron Walden and Guildford.

In Wales only twelve unions provided liquor for their officers, thirty-three unions supplying none. Of the latter the Parliamentary Return gives the particulars in only one instance, that of Cardiff, where the officers of the workhouse and schools were allowed a money payment of 1s. 3d. weekly.

In the House of Common's Return, on the motion of Mr. Whitworth, of alcoholic stimulants used in the Irish workhouses during 1880, out of the 163 unions included in the Return 87 are reported as having supplied no intoxicating drink to the attendants.

Since the date of the Return for 1871, in a considerable number of unions the officers have asked for and received a money equivalent in lieu of the beer. At Brighton no fewer than fifteen of the resident officers and servants engaged in the Industrial School sent in a statement to the effect that they were total abstainers, and requested a grant of money in place of the drink they did not consume. At Banbury the guardians have resolved to allow the master and other officers £4 per annum. During the discussion of the question at Banbury it was stated that in Solihull union the master received £6 a year, the matron £3, and the nurse £3. In Manchester several officers receive milk at their own request, instead of ale and porter.

In only one case which I am acquainted has there been a really pathetic and touching appeal for beer by an official, though a few similar petitions, not quite so heartrending in their terms, have been made. I allude to what the press called "the singular application" to an English board of Guardians in 1880 from the schoolmistress of a union workhouse. This worthy lady applied for an allowance of beer or for 1s. 3d. per week. The beer, she urged, was necessary on account of her health. Will it be credited that neither of these requests, for the "necessary" physic or its value in money, was granted?

All may not be agreed on the propriety of sweeping away altogether the beer allowance to officials, though there are many unions where neither beer nor an equivalent in money is given. But no abstinent or non-abstinent ratepayer, or other person interested in parochial affairs, can possibly object to the officers, in unions where there is a beer allowance at present, being offered the alternative of either an unintoxicating or a cash equivalent. Everyone must acknowledge the fairness of conceding to such officers as cannot conscientiously drink ale, or do not care for it, a money or other equivalent in kind equal in value to the beer to which they are at present entitled. This is a simple act of justice, and cannot but commend itself to all. Not once, but many times, have guardian committees and Poor-law officials strongly urged the propriety of adopting the recommendation of the Special Committee of the West Derby Guardians in 1871, viz., "With respect to the supply of ale and porter to nurses and other officers, we strongly recommend that a money equivalent be granted in place of the daily allowance to such officers as may be inclined to accept it."

Permit me to conclude with the expression of the firm conviction, that procedure in this direction will have the strong and hearty concurrence of the Local Government Board, whose official staff (one of whom, Sir Hugh Owen, has recently been rewarded by Her Majesty for his long and efficient Poor-law services) have all along spared no effort in impressing the importance of this question on the various boards of guardians throughout the land.

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Three Cases of Gout.

Under the Care of Dr. DYCE DUCKWORTH.

Communicated by Mr. SIDNEY DAVIES, B.A.

I.—*Gout in a Sailor.*—Alfred B., *æt.* 63, came to the out-patient department of St. Bartholomew's Hospital on May 8th, suffering from a severe attack of gout in several of his joints. He had been for forty-five years at sea, and was a master mariner when he left his ship, having become incapacitated by the gout. Being, in consequence, reduced in circumstances, he went into the union infirmary for a time. No history whatever was obtainable as to gout or rheumatism in any of his ancestors or relations. One brother, older, has never suffered. He used to drink bottled beer and Holland's gin in moderation when at sea. His first attack of gout occurred fourteen years ago, while he was sailing on the coast of Africa, within four degrees of the equator. The pain seized him about midnight in the great toe. Two days after it went to the ankle. After the attack had lasted a few days it left him for a space of two years. Subsequently the attacks came about every year, and, latterly, three or four times a year. The hands were first affected six years ago, the elbows and knees four or five years ago, and the shoulders and hips since that time.

When he presented himself, the patient had a pallid anæmic appearance. His hair was grey, his teeth strong, and well enamelled. There were no tophi in the ears, or anywhere else. The mucous membranes were pale, uvula large; tongue pale, coated with a thin yellow fur. Hands much deformed; carpus deflected to the ulnar side. Fingers of rather a "paranip" type. Extremities of the ulnae much enlarged. Knuckles everywhere enlarged. Right hand œdematous, puffy and swollen. He was not troubled with cramp in the legs. There was visible pulsation in the brachial arteries. The heart sounds were clear. There was thickening of the bursa over the right olecranon. Urine 1015, acid, contains a trace of albumen, but no sugar. The patient has had no previous illness but "fever." He stated that he slept well, but had to get up three or four times in the night to make water. He was ordered the following prescription:—

Pot. iod., gr. iij.;

Syr. ferri iod., ℥ss.;

Tr. nuc. vom., ℥x.;

Aquæ ad, ℥j. ter die sum.,

and lin. sinapis co. to apply to the affected joints.

When he presented himself at the hospital he had been in continual suffering for six months.

On May 28th he came, and said he felt much better. The medicine was discontinued, and he was ordered

Lin. saponis co., ℥vij.;

Tr. iod., ℥ss.;

to be mixed and applied to the joints instead of lin. sinapis co.

On June 4th he was again improved. Anchylosis existed in many of the phalangeal joints of both hands, only the fore-fingers and thumbs could be opposed, so that the grasp was very imperfect.

August 3rd.—Continues free from pain.

II.—*Gout in a Sailor.*—Peter W., *æt.* 78, came to the Hospital on April 6th to seek relief from an attack of gout, chiefly in the left hand. He had lived at Padstow and at Plymouth, and was formerly a sailor. He was married, and had six children, one had died, four were girls, and the eldest son was living, aged 58, was formerly a sailor, and suffered from gout.

The patient was a man of healthy appearance; his head was bald and shiny; he had no arcus senilis, and was nearly edentulous; the teeth which remained were yellowish; eyes glistening; the nails were striated. There was a well-marked tophus on the left ear, and a doubtful one on the right. The uvula was long and glossy; the skin of his hands smooth and shining.

The first attack of gout seized him in the left great toe eighteen years ago. On the occasion of the second attack his left wrist, instep, and right middle finger were involved in the disease.

The last joint of the right middle finger was much enlarged. The fingers were straight. The bursa over the right olecranon was full of presumably uratic deposit.

The patient did not suffer from cramps, nor from headaches. His urine was acid; sp. gr., 1024; contained a trace of albumen.

Three years ago he began to have attacks of "leadness" at the end of the ring finger, passing to the other fingers, and to the wrist, accompanied by burning pains, alleged to be constant. He was rendered miserable by them, and the discomfort kept him awake at night. The tongue was large; heart sounds clear. The vessels had the hardness of senility. He was ordered the following prescription:—

Pot. bromidi, gr. viij.;

Pot. citratis, gr. xv.;

Dec. chinchonæ pal., ℥j. ter die sum.;

Conf. sulphuris, ℥j. p. r. n.

April 9th.—Patient's right hand has been swelling since the 6th, and is affected with much pain, but it is not like ordinary gout, accompanied by œdema. The pain in the left hand is the same. Medicine changed to

Tr. colchici sem., ℥xv.;

Mag. carb., grs. x.;

Aq. menth. vir., ℥j. ter die sum.

13th.—The right hand is relieved. Ordered

Ung. veratriæ (B.P.) ad manum sinist. applic.

Rpt. hst. colchici.

27th.—The veratria gives no relief. Ordered

Lin. chlorof.

Pit. col. co. c. hyoscyam, gr. x. p. r. n.

Pot. cit, gr. xx.;

Inf. gent. co., ℥j. bis die.

III.—*Acquired Gout—Chronic Interstitial Nephritis.*—William Geoghegan, *æt.* 61, fur-skin dresser, came to the out-patient room complaining of weakness and pain in the left side. On examination no physical signs were found in the chest. But there were tophi in the ears; the joints between the first and second rows of phalanges were enlarged; the fingers were straight, and the hands in the same lines with the arms. There was slight œdema in the legs. Over two of the phalangeal joints were deposits (doubtful tophi.) The urine was acid; sp. gr. 1018, no albumen. Pallor and œdema of eyelids.

The patient stated that he had the first attack of gout six or seven years before, in the left great toe; he woke up one morning with pain and swelling there. The attack lasted six weeks. It was followed in eighteen months by another attack, which affected the right wrist. The fingers were attacked afterwards.

Patient had lived in England for forty-five years. When in Ireland, his native country, he used to drink whisky and water, and a little beer; since he came to England he had drunk chiefly beer. None of his relatives, as far as he knew, had ever suffered from gout. He was ordered *haustus quinæ c. ferri* of the Hospital Pharmacopœia, with mag. sulph., gr. xv.

Remarks by Dr. Dyce Duckworth.—Two of the foregoing cases were in the persons of sailors. Gout is certainly less common in sea-faring men than amongst landmen. There must be a reason for this, and if we could learn exactly what is the cause of this exemption, we should be better conversant than we are with the nature of gout. In both of these cases the patients were advanced in years. Dr. Duckworth could only recall one instance of a man who lived almost constantly at sea, a master mariner, and who was under forty years of age, who suffered from attacks of gout.

In the first case, a severe attack came on at sea, and in the tropics. The man was then forty-nine years of age. It was a "classical" attack of podagra, seizing a big toe-joint in the middle of the night. The patient could trace no hereditary acquirement of the disorder. He had drunk moderately

bottled beer, and a little Holland's gin while at sea. He presented no appearance of having been an excessive drinker. No evidence could be obtained of uratic deposit in any part. Would it be proper in such a case, therefore, to question the truly gouty nature of it?

We must suspend judgment as to the presence of urates, but we must accept the belief of Mr. Jonathan Hutchinson, which clinical observation and post-mortem research both support, that gouty arthritis may be independent of uratic deposition. And, in like manner, joints may be seriously disorganised and incrustrated with urates without any ordinary manifestations of gouty arthritis, such as pain, inflammatory signs, &c. We recognise gout by its type, by what it does, and by what it does not do. The points in this case which declare for true gout are, the occurrence of the disorder in a male of certain age, in a certain joint at a very definite period; further, the recurrence of other attacks at intervals, the arthritis not being of progressive character, and the deformities unaccompanied with those bony outgrowths which are so significant of osteo-arthritis. The supervention of renal affection in that form, so often met with in the gouty, and the other physiological features, all point in the direction of gout, and not in that of rheumatic or other arthritis.

The second case was in a man of 73, who had formerly been a sailor, afforded a history of the first attack when he was 55 years of age. He appeared to have been a temperate man. His son, also a sailor, evidently inherited his gout from him. Tophi were present in this case, and the occasional symptom of "dead fingers" occurred in a very annoying degree. The arterial spasm is noted to be somewhat more common in those who are goutily disposed than in other individuals. No relief was gained for the distressing sensations in the left hand; veratria and chloroform liniment were unavailing, and the patient returned to the country at the end of three weeks. Old people bear pain badly, as a rule, but I cannot doubt that relief might have ensued from full doses of bromides given early in the evening.

The third case affords an example of what is far from uncommon, viz., the acquisition of true gout by an Irishman, who alters the mode of life, and takes up his residence in London. This man had lived forty-five years in England, and had adopted a sedentary occupation, and taken to beer-drinking. Gout is known to be extremely rare in Ireland and Scotland. Evidence is forthcoming, however, that since porter-drinking has become more common in Dublin than it was formerly, there is a decided increase of true gout amongst the lower orders.

The reasons that led to suspicion of chronic interstitial nephritis in this case were, the low specific gravity of the urine, the œdema of eyelids, and the glistening conjunctivæ, together with the swelling of the lower extremities. The existence of albumen is not necessary to certify this diagnosis in the presence of so many plain symptoms associated in a case of chronic gout.

Special.

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

CYSTIC TUMOUR ON THE VULVA.—At the Société de Chirurgie, M. Despres communicated an observation of a little girl, 8, who was brought to him for menorrhagia. On examination he found at the vulva a tumour of the size of a nut, occupying the opening in the hymen, and almost completely obliterating the meatus. The tumour was detached by the ligature. Examination proved it to be a cystic tumour containing black blood. M. Despres considered it to be one of those vesicular vascular polyp very rarely observed amongst little girls in France.

COXALGIA.—M. Verneuil wished to draw the attention of the Society, upon an accident that he had observed in the course of coxalgia, and which was never mentioned sufficiently, in text books he meant, that particular kind of relapse after apparent cure of the disease. He cited the following case as typical:—Five years ago he had been called to see a young girl affected with coxalgia of a benign form. He put the limb in an immovable apparatus, and the cure was very tedious. However, fifteen months ago he was able to pronounce the cure as complete. Both limbs were exactly of the same length, and there was but a very slight degree of stiffness in the articulation. Six months after-

wards he was called to see the child again, and he found considerable deformity in the affected side; a marked shortening and flatness of the gluteal region. There was no swelling, no pain, nor any trace of inflammation. M. Verneuil diagnosed, contrary to the opinion of other medical men, a paralysis of the psoas sartorius and abductor muscles, which proved to be the case; as chloroform being administered, he was able to correct the deformity. The child was again put into an immovable apparatus, and faradisation employed. The results were admirable. These facts led M. Verneuil to find in the muscular system the physiological explanation of the two periods of coxalgia. As is well known, in the first stage there is abduction, rotation outwards, and apparent lengthening, and permanent flexion, all such as would give contraction of the gluteal muscles, and the psoas. In the second period, on the contrary, there is abduction, rotation inwards, and shortening. The articular inflammation extends to the capular muscles, the inflammatory contraction of the psoas causes permanent contraction, that of the glutæus medius and minimus, to lengthen with abduction. After a certain time these muscles become atrophied and lose their strength, then the inflammation extends further, to the abductors and the sartorius, which produces rotation inwards, and shortening. Bearing the above facts in mind, electricity should be employed to strengthen the muscles.

TREATMENT OF ABSCESS OF THE BREAST.—Dr. Pagnet, of Lille, adopts the following rules in the treatment of abscess and phlegmon of the breasts:—As soon as fluctuation is recognised, he makes a puncture with a broad bladed bistoury without incision. More frequently he multiplies these punctures, and afterwards by pressure and constant washing out of the abscess by antiseptic lotions, he succeeds in effectually emptying the breast of all purulent matter in a very rapid manner, and without leaving any apparent trace of the operation.

INJECTION OF COLD WATER.—The injection of cold water, even when used therapeutically, does not seem to be free from danger, as a case reported by the clinical professor of the hospital at Limoges would prove. A man entered the hospital to be treated for a simple gastritis, and washing out the stomach with cold water was ordered and performed. After the third operation the patient had a violent shivering fit, and the next day signs of pneumonia in the left lung were observed. On the sixth day the man died, and the autopsy showed the existence of inflammation of the parenchymatous tissue of the lung in its whole extent, while the right lung was found to be greatly congested. A similar case occurred in Paris at the hospital Tenon. A man, 66, was admitted for a simple chronic gastritis. After trying in vain different remedies, washing out the stomach was ordered, but in this case, warm water was used. After the fourth washing or *lavage*, he was taken with a shivering followed by high fever, pneumonia of the left side declared itself, and terminated fatally on the fifth day. This last case would show however, that the danger cannot be wholly attributed to the degree of temperature of the liquid, but to the operation itself.

In the *Annales de Gynécologie*, M. Tarnier recommends the following procedure for exploring the mucous membrane of the rectum for fissures, &c., in women. The index of the right hand is introduced into the vagina, and bent in the form of a hook; the pulp of the finger is pressed gently from above downwards, and outwards against the recto-vaginal wall, so as to make it come out by the anus covered by the rectal mucous membrane, and thus fissures, ulcers, and hæmorrhoids, can be easily recognised and dressed. This operation is very easily practised in women who have borne children. The pain is slight.

The *Gazette Hebdomadaire* has published a series of letters from medical men, who are with the troops in Algeria, from which it would appear that the sanitary state of the troops is deplorable, and that means placed at the disposal of the medical men are entirely inadequate, and in some cases the ambulance department is wanting in everything; medicines, clothing, beds, &c. Upon these facts, the Minister of War ordered a report to be drawn up by the Surgeon in Chief of the expeditionary forces, and this report seeks to contradict the statements contained in the *Gazette Hebdomadaire*, but the political journals here are not inclined to put much faith in it.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 28, Bombay 29, Madras 38, Paris 24, Geneva 22, Brussels 20, Amsterdam 21, Rotterdam 18, The Hague 20, Copenhagen 15, Stockholm 19, Christiana 16, St. Petersburg 40, Berlin 23, Hamburg 22, Dresden 25, Breslau 27, Munich 30, Vienna 23, Prague 25, Buda-Pesth 27, Rome 24, Naples 35, Turin 18, Alexandria 35, New York 29, Brooklyn 28, Philadelphia 24, and Baltimore 27.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 28TH.

The President, JOSEPH LISTER, F.R.S., in the Chair.

Mr. C. T. DENT ON

A CASE OF STRANGULATED HERNIA (LITTRÉ'S) OR PARTIAL ENTEROCELE.

After remarking that the term "Littré's hernia" had now acquired rather a loose significance, and that several varieties had been described since M. De Littré's original article, the author narrated the case of W. G., *æt.* 37, a phthisical, emaciated man of intemperate habits, who was admitted into St. George's Hospital in February, 1881. The patient had never noticed any rupture till the day before admission, when he observed a tender swelling in the left groin. Two days previously he had vomited after taking food. The day after admission he vomited again after taking some milk, and the bowels acted several times. The swelling was the size of a small Tangerine orange, and slightly tender. No impulse; tongue dry and red; marked distress. The diarrhoea continued, and while he was being put under ether he passed a quantity of fluid feces. The hernial sac was greatly inflamed and thickened, and the parts so matted together that careful dissection was necessary. On dividing a slight constriction the hernia was felt to go back; the sac was not opened. The tissues were so lax that the entire sac was readily displaced beneath Poupart's ligament. The symptoms were relieved for the first two or three days, but persistent diarrhoea then set in and proved fatal on the sixth day. Post-mortem—Extensive disease of the lungs was found. The hernia proved to have consisted of a portion only of the circumference of the jejunum; a dark semigangrenous ring corresponding to the constricted part was seen on the gut. Extensive enteritis of the ileum was found, which may have accounted for the diarrhoea. The case resembled those described by M. De Littré in that there was no intestinal obstruction, faces passing freely; in that hicough was absent, the vomiting not persistent or stercoraceous, and the abdomen was not distended. It was peculiar in the following points: (1) It occurred in a man; (2) The jejunum was involved; (3) The hernia must have existed for some time without being noticed; (4) There was no diverticulum or sacculatum of the gut, which on post-mortem was found at a considerable distance from the sac. In conclusion, the author advocated the removal of great part of the hernial sac when, as in this case, it is thickened, inflamed, and ulcerated, and the closure of the neck of the sac by deep sutures.

THE PRESIDENT suggested that the absence of constipation in this case might be consequent on the partial obstruction of the gut; obstinate constipation, however, was not commonly met with in omental hernias, and those of the cord also. He remembered one case in Edinburgh Infirmary in which all the symptoms of a femoral hernia existed, but when explored there was found only a mass of fat, constricted by Gimbernat's ligament, which was divided. The patient subsequently dying, and post-mortem examination showing this to be the only obstruction.

A VISITOR remarking on the question whether the sac should be opened and the bowel exposed, said that in King's College Hospital Mr. Wood was in the habit of sewing up the orifice of the sac in such cases, and dissecting away the parts below the ligature, and that the practice was a good one results attested. He thought peritonitis might be incurred through the operation recommended by Mr. Dent.

MR. HAWARD thought Mr. Dent's object in leaving the sac open was to favour the escape of fluid from it, and not from the peritoneum, this being an argument for opening the sac. He considered it very undesirable to return into the peritoneum any inflammatory product escaping from the opened sac. By opening this and sewing up the edges support would be given to the hernia, but the lower part should be cut away, or left freely open for the escape of fluids, &c.

MR. HOWARD MARSH commented on the truth of Mr. Hutchinson's explanation that peritonitis in these cases is always due either to the escape of fluid into the peritoneal

cavity, thus necessitating the utmost caution to prevent such a misfortune, or the operation itself. He himself had never seen a case to which this reasoning did not apply.

MR. DENT urged that the existence of even profuse diarrhoea in these cases did not contraindicate operation. He had mentioned opening the sac in reference to the one case only. A drainage tube was necessary for the relief of possible effusion into the wound; he did not intend to hint that peritoneal suppuration was thereby to be relieved.

DR. T. CHURTON (Leeds) on

A CASE OF DOUBLE HÆMORRHAGIC PLEURISY, WITH FORMATION OF CHOLESTERIN.

A man, *æt.* 38, of originally good constitution, always temperate, not syphilitic, had in 1876 a wide-spreading axillary abscess, the discharge from which lasted six months, as a result of a wound on the left hand. His health was never perfect after this time, and in 1878 he became positively ailing, was short of breath, and lost flesh. He had no cough, no hæmoptysis, and scarcely any pain in the chest. He gradually got worse until June 1880, when he was admitted into the Leeds Infirmary. He then complained of loss of appetite, wasting to the extent of 20 pounds in 12 months, occasional vomiting, pain in the right side and between the shoulders. Complete dulness on percussion was found in both axillary regions; respiratory sounds, fremitus and resonance were greatly diminished or absent. The dulness was of irregular outline but sharply defined. On exploratory puncture in the left axilla a brown greasy fluid (exhibited) was obtained. It was composed of red blood cells, frayed at their edges, and scales of cholesterolin in great abundance in a highly albuminous but not spontaneous coagulating plasma. There appeared at this time to be only a very small quantity of fluid on this side, but on aspirating the right side in the fourth space, after failing to get anything in the fifth space, two ounces of a dark red fluid were withdrawn. This also contained cholesterolin crystals in abundance, the patient's temperature was normal. There was no disease of other organs. For the next twelve months the left side gave very little trouble, it was aspirated once (Aug. 10, 1881) during that time, one ounce of the same kind of fluid as before, but lighter in colour, being obtained. The right cyst, however, refilled again and again, and the fluid was more deeply reddened then at first. Aspirations were performed on July 4 (four ounces); August 10 (sixteen ounces); November 22 (twelve ounces); December 23 (quantity not recorded); March 3, 1881 (eighteen ounces); May 4 (quantity not recorded). Up to this date his general health had improved, he ate and digested food well, could walk about and do light work easily, especially after each operation; but now, remaining in hospital with a view to the abolition of the pleural cyst by any possible means, but unfortunately, or as it may prove fortunately, became involved in a quarrel with a nurse, and while in a nervous and agitated state drank some cold water, which caused immediately a feeling of chilliness throughout his whole body. He became feverish and slightly delirious. On June 23, thirty ounces of fluid now containing pus-cells though still glittering with cholesterolin, were withdrawn from the right side. On July 2, forty ounces were removed, and on July 10, as the fluid had again accumulated, and the temperature reached 103°, an incision was made at Dr. Churton's request, by Mr. W. H. Brown, the House Surgeon, in the right chest, seventh space, posterior axillary line. Thirty-eight ounces of similar fluid (specimen shown) escaped; the temperature fell to 99° within three days, but then again rose to 103°. Dr. Churton then discovered that there was a recent accumulation of fluid upon the left side and twenty ounces of clear but cholesterolin-bearing fluid were thereupon withdrawn. The patient did not, however, improve. Pulse 120, resp. 23, temp. 102°. He fancied poison was being given to him by various people, and left the hospital on July 19. At home the large drainage tube in his right chest fell out, and he then considerably improved. He continued to take quinine and steel. On Sept. 10 he had pulse 110, resp. 24, temp. 99° (evening). He was still unable to walk across the room. There was a little clear fluid on the left side (explored); no cholesterolin in the pus from the right side. The wound was fistulous and valvular; there were signs of gradual expansion of lung on both sides; a probe passed through the fistula seemed to reach the right lung at once. He went to Bridlington for a month; there he gained six pounds in weight, and otherwise improved so greatly that he could walk a mile. He returned on October 17. Unfortunately the narrow pus-channel became blocked, and he lost ground. On Oct. 27 the following note was made: Pulse 120,

resp. 27, temp. 102°; discharge of pus re-established; he is walking about. The dull area in the left axilla has diminished almost to nothing; a needle passed in at the dullest spot above the seventh rib found nothing. This part of the chest does not in him move in respiration; for this reason apparently there is little respiratory murmur in the lower axilla; fremitus and resonance are found here, but are not nearly so distinct as on the front of the chest, where also the breath sounds are, as they have always been, intensified. The right side is resonant throughout; respiratory sounds, though feeble, are unmistakably heard in the axilla and elsewhere; fremitus and resonance are distinctly present. Two or three ounces of inoffensive pus (without cholesterolin) flow from this side daily. There are no râles. He has some phlegm and occasional expulsive cough. While at rest he has no subjective discomfort. He is going to Scarborough for a month. The author believed that chronic pleurisy had caused the formation of a thick false membrane over a part of the lung (on each side); that blood-cells had escaped by diaporesis into the cyst thus formed; that the false membrane had at length undergone fatty degeneration, having as one of its final products cholesterolin. Dr. Mehn (*Archives Générales de Médecine*, Sept. 1881) asserts (p. 277) as the outcome of very numerous observations that cholesterolin in crystals is never met with in fluids which have not been encysted at least, six months. In this case it was once found in fluid from the left pleura, which had almost certainly not been there many days; moreover, a shred of membrane derived from the left pulmonary pleura which blocked up the aspirating needle was found to consist of small cells and cholesterolin crystals in almost equal quantity. Although Fraenkel states (Ziemssen's *Cyclopaedia*, vol. iv., p. 670) that when pleurisy appears simultaneously on both sides it is commonly of tubercular nature, and moreover (p. 614), that relapsing hemorrhagic pleurisy generally stands in more or less close connection with the eruption of tubercles, yet, having regard to the facts that the patient had continued in fair health and with a normal temperature for a whole year, while frequent aspirations were being practised; that the left chest had become almost normal; that an apparently accidental empyema on the right side had not been fatal; that the part of the right lung formerly compressed had, probably from the suppuration and disintegration of its thick false membrane, been able at length to re-expand to a great extent; and that since the empyema the patient had in every way greatly improved at the seaside once (and might therefore reasonably be expected to do so again), Dr. Churton did not despair of his ultimate recovery.

The PRESIDENT said it would be satisfactory if physicians would narrate their experiences of cholesterolin in the pleural fluid.

Dr. S. MACKENZIE generally considered that blood in the fluid obtained by tapping the pleural cavity indicated the existence of cancer.

Dr. DOUGLAS POWELL inquired if the corpuscles in the fluid obtained were much disintegrated. It was important to ascertain whether the pus consisted of dead cells in such cases, or were genuine living pus cells, which were of much more serious meaning. He had never observed cholesterolin in pleuritic effusions. Might not the substance be due to fatty changes set up by the influence of abnormal corpuscles. He did not think the blood-staining of fluid necessarily indicated cancer, nor that it was of high diagnostic importance.

Dr. T. WILLIAMS considered the most interesting points about the case were the production of cholesterolin, and the fact that the two pleuræ secreted different fluids. The condition of the liver should have been investigated. It was unusual in his experience for lungs long bound down to rise again in the way described by Dr. Churton. Tubercle was not incompatible with an absence of high temperature. He had met with it in cases where there was absolutely no rise at all.

Dr. HENRY GREEN and Dr. SYDNEY COUPLAND added their testimony to the fact that blood might be found in aspirated fluid drawn from non-cancerous patients. Dr. Coupland instanced two cases in proof—one, an old man, died of pyæmia; the other recovered. In neither was cholesterolin found in the fluid. He doubted the propriety of speaking of "living" pus.

Mr. PARKER asked if the abscess in the side described in the paper preceded the pleurisy?

Dr. CHURTON—Yes.

Mr. PARKER—Then might not a connection exist between the two conditions, the one influencing the other?

Dr. SILVER suggested that the cysts might have originated from pressure of fluid in a confined portion of the pleura.

The PRESIDENT said it was interesting to note the rapid formation of the cholesterolin. It was usual to find it only in very old collections of fluid, as in long-standing hydroceles, e.g.

Dr. CHURTON had intended to argue the production of the cholesterolin from the lining membrane of the lung, and not from the fluid, if it were true that in its production time was an essential element. The corpuscles were disintegrated and frayed at the edges. The liver had been carefully examined in response to the suggestion contained in the nature of the fluid first drawn off, but there was never any indication of hepatic disease. The non-tubercular theory was not founded entirely on the low temperature observed, but chiefly on the absence of any wasting during a lengthened period. The relation of the disease to previous suppuration had been considered, but as two years of health had elapsed he had not been justified in eliminating this cause.

Mr. REEVES on

TWO CASES OF MALIGNANT STRICTURE OF THE ŒSOPHAGUS IN WHICH GASTROTOMY WAS PERFORMED, WITH SPECIAL REFERENCE TO ŒSOPHAGOSTOMY IN NARROWING OF THIS TUBE.

After narrating the two cases, he pointed out how, having done gastrotoomy in deference to the wishes of his colleagues, he should proceed to act in any suitable case of stricture of the œsophagus. He said that the most recent information showed that malignant obstruction was most common in the upper part of the tube, occurring in that situation in about half the cases, and although a much larger number of observations were needed to arrive at a correct conclusion, still there was sufficient justification for the rules he wished to lay down, which were the following:—1. That because of the great mortality after gastrotoomy, and also because of the more frequent occurrence of malignant stricture in the upper portion of the tube, œsophagostomy is by far the preferable operation. 2. That even in cases where the stricture is as low down as the manubrium sterni (its depth rarely being very great), œsophagostomy is indicated as a preliminary or exploratory operation, and if it be found that the little finger or sound cannot be got through the narrowing, gastrotoomy may be performed. 3. That if it result that the opening in the œsophagus have been made below the stricture (as in most cases would be desired), the operation can be completed by stitching the mucus membrane to the wound, edges, and the stricture may, if thought proper, be dilated through the opening either at the time of opening or subsequently. 4. That if diseased œsophagus be reached, and no opening into it can be made through healthy walls, then it may be carefully performed, either by the finger or the thermo-cautery. 5. Œsophagostomy has been many times done, œsophagostomy several, and never have these operations caused any grave, local, or general symptoms, or—as operations—led to the death of the patient, whereas gastrotoomy has proved most fatal. 6. The operation should be done on the left side of the neck, and a sound, if possible, be passed, that of Vacca Bolinghieri being the best. The skin incision should be rather nearer the mid-line than that for ligature of the common carotid, and should extend from half-an-inch above the episternal notch to the level of the upper border of the thyroid cartilage. The surgeon should stand on the left of the patient, looking obliquely down and across his or her body. A tube with a funnel-shaped end should be passed, tied in place, and nourishment administered as soon as the tendency to vomit caused by the anæsthetic has passed off. It is necessary to make the opening in the walls with a sharpish stab, to prevent the loose mucous membrane being pushed before the knife. The edges of the wound may be stitched up, and care taken that no food gets into it. 7. The operation should be undertaken before the patient's strength is much exhausted, and even before obstruction is complete, because frequently attempts to swallow produce spasmodic suffocative dyspnœa, as in the first case related. 8. In severe cases of simple, fibrous, or of syphilitic stricture in the tracheal or upper thoracic portion of the tube, œsophagostomy is indicated, as then the operation might be curative, as well as palliative.

The discussion of this paper was deferred on the motion of the President, in order to afford opportunity to Dr. S. Mackenzie to read his paper, several country members being specially present in town on account of it.

Dr. GOLDING BIRD promised to open the discussion on Mr. Reeves's case by bringing before the Society a report of five similar cases operated on by him in the past year.

Dr. STEPHEN MACKENZIE ON

A CASE OF EXCESSIVELY HIGH TEMPERATURES.

The patient was a woman, *æt.* 42, who thirteen years before had met with an injury to her leg, which was followed by a persistent ulcer. Necrosed bone had on occasions been removed, and amputation of the limb previously recommended. The patient came under the care of Mr. Rivington in 1878, when the left thigh was amputated at the lower third. She was re-admitted on February 25th, 1879, for painful affection of the stump, which was red and inflamed. It was thought to be erysipelatosus, and she was placed in the isolation ward. She had some rigors, followed by pneumonia at the right base. On March 17th her temperature was found to be 108·8°, and twenty minutes later 111; a quarter of an hour later, 105·8. On the following day, two thermometers, one in each axilla, gave 110·6 and 111. On many occasions very high temperatures were taken—as high as 108 and 111 between February 20th and April 22nd. On April 21st, Mr. Rivington opened the stump antiseptically, and removed a piece of bone. After this, with the exception of the day following the operation, the temperature did not exceed 102. The case took an ordinary course, and the patient was discharged cured in August. The pain did not at once leave the stump, and convalescence was slow. The patient was re-admitted, under Mr. Rivington, on October 21st, 1879, for pain in the stump. Another piece of bone was removed. The stump remained painful, and pain and distension of the abdomen, with vomiting, were complained of. It was for these symptoms, and to investigate the peculiarly high temperatures, that the patient was transferred to Dr. Stephen Mackenzie's care on December 31st, 1879. The patient was then thin, but not unhealthy-looking. The abdomen was distended and tender, but no tumour or bone detected. The stump was erythematous. The patient frequently vomited. It was elicited that the patient had taken opium for about twelve years. No important peculiarity, other than the above, was noticed until January 13th, 1880, when she was stated to have had a slight rigor, and temperature was found to be 109·2. The pulse was 72, and the respirations 24. On January 14th the temperatures were—at 1 p.m., 108; 2 p.m., 108·2; 4 p.m., 107·4; 5 p.m., 108·5; 7 p.m., 109·6; 8 p.m., 106·8; 9 p.m., 102·6; 11 p.m., 106·4; 12 p.m., 113. On the 15th—3 a.m., 113; 4 a.m., 113; 5 a.m., 111; 10 a.m., 107·2; 12 a.m., 111·6; 2 p.m., 112·2; 4 p.m., 114; 6 p.m., 109·2; 8 p.m., 110·2; 10 p.m., 113·3. These are given as examples of the thermometric records. On January 16th the highest temperature was 114·2; on the 17th, 105·8; on the 18th, 112; on the 19th, 136·6; on the 20th, 108; on the 21st, 109·2; on the 22nd, 120·8 (the highest recorded). Probably many of the readings would have been higher, but the thermometer did not, as a rule, register higher than 111 or 113. On the 23rd, 116·6 (temp. in axilla, 105, in rectum, 99, in mouth, 98); on the 24th, 111·4; on the 25th, 111·2; on the 26th, 116·8; on the 27th, 110·6. After this date the temperature was irregular, but did not exceed 103 until April 6th, when 113 was recorded. Ten minutes after this last observation a thermometer in each axilla gave 99 in each. On April 10th, temperature, unwatched, 104, watched 99. On May 11 another high temperature was recorded. When a thermometer was placed in axilla it registered 110. Taken five minutes afterwards by the nurse, who watched her, it was normal. The same thing was repeated many times. With two thermometers in the same axilla, considerable differences were observed. From May 24th to July 3rd, when she was discharged, the temperature was about normal. Throughout the time she was under observation, Her general condition remained much the same; but the vomiting ceased, and the abdominal pain was not complained of. There did not appear any important constitutional disturbance. When the high temperatures were recorded, the pulse at such times was usually between 70 and 80, and the respirations between 20 and 30. Discharged September 24th. The patient was re-admitted on

August 16th, 1880, complaining of epigastric pain, abdominal swelling, and vomiting. High temperatures were again observed. On August 19th, a temperature of 110 was recorded. A fresh thermometer was immediately placed in the axilla, and the temperature found to be normal. On September 18th, the readings of two thermometers in the same axilla gave 105·5 and 101. On no occasion, when thermometers were held in the axilla, or the patient closely watched, were the excessively high temperatures observed. The patient has been visited within the last few days; her general condition was the same as when she left the hospital; her temperature was not taken. The author expressed his belief that the temperatures were *fictitious*, and on the following grounds:—1. The patient was a neurotic woman, and "an educated hospital patient"—*i.e.*, knew the importance attached to high temperatures. 2. That when on one occasion the temperature was taken simultaneously in mouth, rectum, and axilla, the temperature in the mouth and rectum corresponded, and were normal; whilst that in the axilla was six degrees higher. 3. That when two thermometers were simultaneously placed in the same axilla there was as much as from one to four and a half degrees difference. 4. That there was no correlation between the high temperatures, the pulse, and respirations. 5. That on no occasion when the thermometer was held in the axilla, or the patient closely watched, was an excessively high temperature obtained. When accused, subsequently, of causing the high thermometric readings, the patient absolutely denied the charge. The author stated that he did not wish to imply that all the recorded cases of similar high temperatures were of the same kind. The fact that some cases, recorded by good observers, were believed to be genuine, rendered it desirable that a fictitious one should be exposed to put all on their guard in their investigation.

Mr. J. W. TEALE (Scarborough), who had recorded the first case of the kind in the Clinical Society's Transactions, November, 1875, was inclined, with Dr. Mackenzie, to doubt the reality of the majority of recorded cases. The patients are, as a rule, hyperæsthetic and neurotic, a development of the latter half of the nineteenth century, Dr. Mackenzie's case differed from his own in that no importance was attached to the high temperature at the time; and also in that the patient was a healthy woman, ignorant of the significance of thermometry, being, moreover, incapable by reason of her injury, of manipulating the instrument. He suggested that a committee should be nominated by the Clinical Society to observe the progress of any future case recorded, and which should be at once communicated to them. He would undertake to send immediate information of the fact should any recurrence of the phenomena take place in the patient formerly observed by him. He had obtained the report of a case in which temperatures of 133° and 127·6° were said to have been reached.

Dr. MAHOMED mentioned a case under Dr. Watson and himself at Guy's Hospital, and whom Dr. Habershon had treated for anæmia without any indications of unusual temperature having been noticed. During her later residence in hospital, however, extraordinary readings were obtained from her, and in several instances the observations were made in the presence of several of the staff. On one occasion the instrument registered 102°, 106°, and 115°. Even when the thermometer in the axilla registered 128° her body did not feel unduly warm, and the surface thermometer never showed a high degree of heat, nor was the non-registering thermometer driven to any unusual height. It was eventually discovered that this patient utilised the respiratory movement as a means of driving up the mercury. She was an excitable girl, but never confessed to the fraud although many occurrences induced the belief that she was shamming. Friction of the bulb of the thermometer between the finger and thumb for ten minutes would, said Dr. Mahomed, force up the index, as also would breathing on it through folds of linen.

Dr. T. WILLIAMS asked if any observation had been made on patients during the hours of sleep?

Dr. GEORGE HARLEY said that Wunderlich had recorded a case in which one hour before death the temperature of the body was 112°, and one hour after death 113·8°. This also reminded him of a girl in University College Hospital who died from pericarditis in winter, and fifteen hours afterwards, when on the post-mortem table, the corpse was abnormally hot; the chest smoked when opened and the heart was

uncomfortably warm to the touch. It was always, he continued, extraordinary to observe the great fluctuations in temperature which sometimes accompany disease, but are never associated with health; and the circumstances attending existence in polar and tropical climates where the body temperature maintains the same average heat presented a fact of a marvellous kind in the same relation. In a girl there were great variations; and Goodrich recorded a case of brain softening in which the temperature of the patient was 130°. It was an error to regard all variations of temperature as due to the same cause. He would, with the permission of the Society, put his opinion on the subject in the form of a paper, on which, together with Mr. Mackenzie's report, discussion might take place.

The PRESIDENT, having thanked Dr. Harley for his proposal, accepted it on behalf of the Society.

Mr. RIVINGTON thought Dr. Mackenzie had taken a correct view of the case, that, viz., it was one of fraud. He himself had delayed adding notes to the report of the case already published because it was then incomplete. He believed the patient had tampered with the stump, several indications suggesting this during her stay in hospital. He would not, however, conclude that all cases of high temperature were fictitious.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Et c. Hauteseuille, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILKINER and ROGERS; Philadelphia, by Dr. BRINTON, post free in advance, 5½ dollars (£1 2s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order

ADVERTISEMENT SCALE.—Whole Page, £5 0s. 0d. Half Page £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth Page, 12s. 6d.

Small Announcements of Practices, Assistances, Vacancies, Books, &c., of Seven lines or under, 4s. per insertion; 6d. per line beyond. Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, NOVEMBER 2, 1881.

THE ROYAL COMMISSION ON MEDICAL REFORM.

THE list of Irish witnesses which we gave last week was supplemented since our last issue by the hearing of the testimony of the following gentlemen:—Dr. Richardson, for the Medical Defence Association; Dr. Redfern,

on behalf of the Queen's University; Dr. Collins, for the Irish Apothecaries' Hall; Mr. Tomes and Mr. Edgell for the Dental Association; Rev. Dr. Haughton, on behalf of Dublin University; Dr. Greenwood, for the Victoria University; and Professors Struthers and Young for the Aberdeen and Glasgow Universities.

We understand that the Commission has now wound up its evidence, and that its members have been asked to send in their individual recommendations in order that a report may be prepared as soon as possible.

So far as the examination of witnesses has enabled us to form a judgment respecting the probable nature of that report, we anticipate that it will probably contain two propositions—first, that the General Medical Council must be reconstructed, and reduced in number if possible, and that provision must be made for increased representation of the profession at large, and for curtailing the influence of the licensing bodies which is now dominant in the Council. Secondly, that a State examination should be created, following upon and superior to the qualifying examinations of licensing bodies, and that these should have no validity as licenses to practice, or titles to be entered on the Medical Register, but should be simply qualifications preliminary to the State examinations.

This proposal for establishment of a State examination would naturally occur to anyone as a ready and reasonable means of settling the apparently irresolvable differences of opinion and interest between licensing bodies. But, on closer examination, it will be seen to provide no remedy whatever for the abuses which the Commission has been created to deal with, and we, therefore, hope that the report of the Commission will not contain any such proposal. The chief incentive to a lowering of the educational standard of the medical profession is at present, admittedly, the competition for fees amongst licensing bodies. These institutions have, speaking generally, displayed unmistakably their readiness to sell diplomas to all comers at the highest possible price and on the lowest possible educational terms, and they have been deterred from engaging wholesale in this traffic solely by the consideration that it would spoil their market to sell too cheap. They have recognised the wisdom of keeping up appearances and trying to retain *prestige* by rejecting the utterly ignorant claimants for their licenses, and thus competition has had a certain beneficial effect. Now, if a State examination were erected as the sole portal of admission to the profession, this wholesome competition of *prestige* would cease at once, because no collegiate license would have any value as an evidence of professional education. It would not, in the least, matter to the student what license or degree he took, inasmuch as it would be only a formal permit to present himself for the “Staats Examen.” Therefore, he would—as a matter of course—buy the very cheapest and easiest qualification he could find in the medical market, and—having obtained the necessary passport to present himself for the State examination—would then set to work to learn his business before offering himself for that examination. Moreover, it would be the interest of the licensing body to make licentiates on any terms, because it would have to depend chiefly for existence

upon the granting of its Fellowships and other higher medical distinctions, and the greater the number of its licentiates, the greater would be the demands for its higher degrees.

For these reasons we believe that an independent State examination would greatly stimulate low-class competition amongst licensing bodies, and increase the evils which it is intended to remedy.

But there is another reason why we hope that the Commission will not adopt the proposal of a State examination.

We wish to see a Reform Bill passed next session, and with this object we desire that a practicable measure, which will not evoke unnecessary opposition, should be placed in the hands of Parliament. If the Royal Commission recommends conjoint examination, as proposed by Mr. Hardcastle's Medical Reform Bill of last Session, it will achieve what is to all intents and purposes a State examination, and its recommendation will have the support of the profession and of most of the licensing bodies. If it proposes an independent State examination it will arouse the bitter and persistent opposition of every licensing body in the kingdom, and will not have the active co-operation of the profession at large. There would, we think, be no chance of the passing of such a proposal unless the Government undertook to force it through Parliament as a party measure, and, therefore, as we anticipate that the attempt at such legislation would result in no legislation at all, we earnestly hope that the Report of the Royal Commission will not take this line.

A MODEL FEVER DEN.

THERE is a certain class of writers and thinkers who are never weary of declaiming against the uselessness of much, if not all, the preventive sanitation that has been the outcome of recent decades of work and teaching. These persons are divisible into two great classes accordingly, as they are influenced by ignorance, complete or partial. The completely ignorant, that is, fanatical section, incessantly prate of the uselessness, and it may be the impiety, of interfering with traditional dirt, and the ills it carries in its wake; as it was in the past let it be in the future they say; they deprecate as sacrilegious any attempt to alter or improve what served the purposes and needs of their ancestors, and blinding themselves to the argument of facts, refuse to see any improvement in the condition of their country effected by hygienic surroundings with which the bygone centuries were unfamiliarised. Such beings it were idle to discuss with; they cannot be reached by demonstration; they cannot be influenced by proof. The second party of obstruction, however, occupies a different ground. Calling to aid certain fundamental truths respecting epidemics, they distort them in the bearings on scientific questions involving the theories of disease, and unable, or unwilling, to enlighten their own ignorance by further study of the problems before them, they dogmatise on points about which the pioneers of preventive medicine are concerning themselves, and particularly in regard to the question of epidemiology. More than one well-

known name will occur to our readers as examples of those here referred to, and in defence of the stubborn obstinacy with which they adhere to profound convictions on the etiology of epidemic outbreaks, it unfortunately happens that events from time to time occur to give them a semblance of reason. Yet the assertion that improved sanitary arrangements in dwellings and towns may not be depended on to remove even all the melancholy consequences that frequently arise in our midst to mock the endeavours of health reformers, has no force for the well-informed physician. He is at once able to allot the proper degree of importance as disease producers to unhealthy surroundings, and with power to pursue in its details the plan approved by scientific reasoning for their removal, can confidently predict the destruction for the future of the deleterious agency.

A striking proof of this is just now afforded in London itself, and in one of the wealthiest parishes in the metropolis. In Marylebone there has recently been exposed a fever den of the worst possible type: a collection of houses utterly unfit to be the abode of human beings, and so constructed, or rather, so ill-constructed as to constitute a breeding place for fever of the most malignant type. Since August last fourteen cases of typhus have been removed from four houses in Charles Street, Lisson Grove; and in all no less than thirty cases have arisen in the limits of this devoted thoroughfare. As a matter of course, examination of the houses reveals an utterly disgraceful condition of insanitation, four of the dwellings being described as resting on a bed of black, filthy sewage, from five to six feet in depth. This state of things is necessarily of no recent occurrence, and we scarcely feel surprised to learn that the state of the houses in this neighbourhood evoked the expostulations of the sanitary officer long before the present epidemic spread its ravages round. It always happens in great cities that population is most confined in the least appropriate spot, and in this respect Charles Street, Lisson Grove, offers no exception. We learn that in one room five and six inmates had their home in many cases, while the whole street of thirty-three houses gave abode to four hundred and twenty-three persons. Thus densely crowded they were subject to most favourable conditions for the immediate and destructive spread of any epidemic fever; and that terrible havoc has been committed among them the records of the week convincingly attest.

The state of matters in the "model parish of Marylebone" is something more than a dark disgrace to the metropolis; it is a very present danger to the whole of London, for even now we cannot with any certainty declare that there is a district in London that may not contain all the conditions needed for the full development of a specific poison once received in it. Hence it behoves everyone to have the utmost care for his own well-being, not only by insisting on the thorough purification of a now infected region, but by demanding the adoption of preventive measures in every situation where possible danger may be lurking. In spite of opposition and denial the germ theory of disease is par and parcel of the professional creed of every educate

practitioner; and with the recognition of its influence on the spread of infection goes also a knowledge of the means whereby the progress of the latter may be checked. It almost appears, however, that in Marylebone itself endeavours at prevention are liable to be hindered by mere considerations of a monetary character, and that the question of landlordism may arise to bar the introduction of drastic measures such as can alone be trusted to effectually cleanse the fevered neighbourhood. Local authority is seemingly powerless to order the changes imperatively demanded, and beyond the immediate pressing duty of local disinfection which it is incumbent on the parochial officials to see carried out, no steps can be taken such as would involve the complete destruction of a pestiferous neighbourhood. This cannot but be regarded as a serious matter, and one on which the public voice may rightly demand to be heard, and the requirements formulated by it be attended to. If local powers are impotent to command the alteration and improvement rendered necessary, then surely this is an occasion for invoking imperial aid, since a people's health is at stake as against an owner's rights. We need not, however, discuss this point here, our object being to insist on the pressing obligation there is to so act as shall ensure the impossibility of a repetition of the dread visitation which so recently passed over the parish of Marylebone. It will be well, too, if the warning conveyed by this epidemic is accepted in time, and a thorough cleansing of the numerous dens which serve as so many potential centres of infection in the city of London follow the exposure brought about in Marylebone. In pursuance of a plan with this end in view all minor considerations must give place to the paramount public interest, for so long as such spots exist in our midst so long are we subjected to the dangers of sudden pestilence. Accumulated filth is ever potent to serve as an important factor in the development of diseases; there needs only the introduction of the germs of ill to ensure the rapid spread therefrom of irresistible evil, and the prevention of such occurrences is the first and most important duty of health officers. How far these latter have failed in the fulfilment of their task, and how far this cause is blameable with the recent outbreak is a question that must some time be answered. It is a difficult and a dangerous matter to discuss it in its details now, but later on we trust it will receive full and fair attention. At present there is enough to do in remedying the mischief already incurred.

AN ANTIDOTE FOR SNAKE-POISON.

THE inconvenience and uselessness of discussing medical questions in lay journals are well illustrated by a letter on a supposed newly-discovered antidote for snake-poison, which appeared in the *Times* on the 28th ult. The writer of this letter, a Brazilian, wishes to claim for Dr. J. B. de Lacerda, of the Laboratory of Experimental Physiology in Rio Janeiro, the merit of having shown that permanganate of potash effectually counteracts the pernicious effects of snake-poison on the animal economy, and in order to do this, he quotes three cases

in which Dr. Lacerda's antidote was employed, and in which its efficacy was, he thinks, conspicuously and conclusively demonstrated. The first case is that of a negro labourer on Captain Rezende's coffee estate, who, having been bitten by a snake just above the ankle, displayed all the characteristic symptoms caused by snake-poison, until his master injected into him a little of the solution of permanganate of potash, when he recovered so rapidly and completely that he was able to return to his work next day. The second case is that of a negro at Barra de S. Joas, who was bitten by a jararaca, a most venomous snake, and who was insensible, with a swollen limb, and bleeding from the nostrils when carried to the engine house, where Mr. Lehmer, the manager, injected permanganate of potash with the effect of restoring him, almost instantaneously, to sound health, so that in four hours he went back to work. The third case is that of Mr. William Broadbent, of the Santos and Jundiaby Railway, who was bitten in the left hand by a jararacussu, also a very poisonous snake, on the 22nd of August last, and who escaped with nothing worse than a little inflammation on having permanganate of potash twice injected into his hand. "I presume," says the Brazilian, having finished his narrative of these cases, "that the foregoing evidence is conclusive enough," and no doubt many of the readers of the *Times* will think so too, and conclude that the snake may now hide its diminished head, and finally sheath its fangs, its vile arts having been effectually circumvented. But it is just here that medical experiences intervene, and recommends caution and a suspension of judgment. We do not mean to assert that the permanganate of potash is not an antidote to snake-poison. The well-known antiseptic properties of this agent, its actions as a caustic, deodoriser, and corrective of offensive evacuations, would predispose us to believe that it might decompose snake-poison, if brought properly and timeously into contact with it, just as it oxidises many other unstable organic compounds. But what we do mean to assert is that no proof whatever is adduced by the *Times* correspondent that permanganate of potash is an antidote to snake-poison. The fallacy into which he falls is just that into which so many medical amateurs are betrayed. He assumes that the recoveries in the cases he quotes were attributable to the remedy which was used. But spontaneous recovery from the effects of snake-bite is by no means uncommon, and a little investigation makes it evident that where there has been an appearance of success in the use of antidotes in cases of snake-bite, the favourable result has depended not on the neutralising or antagonistic action of the remedy so much as on the fact that the quantity or quality of the poison was defective. Sir Joseph Fayrer has shown that when spontaneous recovery takes place after snake-bite, or when a reputed antidote seems to counteract the venom, the snake may have been exhausted, or may have wounded without inoculation, or with the inoculation of a quantity of poison insufficient to cause death. Dr. Weir Mitchell has pointed out that there is in the rattlesnake an arrangement of sphincters round the fangs which enables it to bite without shedding any poison. Even when the snake-poison is undoubtedly introduced into the circulation, the rapidity and severity of its effects will depend in great

measure on the age, weight, and constitutional condition of the person bitten, and on the situation of the wound.

A few years ago one of the oldest of antidotes against snake-bites, viz., ammonia, with which Fontana experimented at Florence above a hundred years ago, was re-discovered, and we were assured that its injection into the veins prevented death, and mitigated all the symptoms of snake-poisoning. But several series of experiments since performed have dashed the hopes thus awakened, and shown that ammonia must take its place with Tangore pill, arsenic, quinine, ipecacuanha, Aristolachia indica, and many other drugs which have from time to time enjoyed popular confidence, but which have all failed to stand the test of scientific investigation into their power as antidotes to the poison of snake-bites. Dr. Lauder Brunton in this country has administered ammonia internally, injected it into the areolar tissue and into the veins, in animals to which the cobra poison had been administered, and has never seen any beneficial results. Sir Joseph Fayrer has tried it with as little success on the human subject in India, and Mr. Richards, of Balasore, and Dr. Wilson, of Maradabad, conclude as the result of their observations that the intravenous injection of ammonia is not followed by any diminution of the effects of snake poison.

It must, we fear, be admitted that no antidote to snake poison has as yet been discovered, but the search for such an antidote need not, therefore, be abandoned in despair. On the contrary all recent investigations into the nature of the poison, its absorption, excretion, and mode of action on the nervous system encourage the hope that its lethal effects may yet be effectually obviated; its action arrested and, its virulence broken up. It is the merit of these investigations that they have cleared away confusion and doubt, and made evident the directions in which antidotes and antagonists must henceforth be sought. A careful perusal of these investigations almost warrants the belief that, but for the miserable epidemic of sentimentalism and anti-vivisectional fanaticism which has afflicted this country of late years, and virtually put a stop to original medical research, some sure antidote to snake poison would now be in our hands. We seem to be standing on the threshold of the discovery: a few well directed series of experiments might conduct us to the goal, but these cannot be undertaken, because some silly women and selfish officials shrink from the idea of inflicting pain on a few rabbits and guinea-pigs. And in the meantime upwards of 20,000 human beings perish annually in India alone, in indescribable torture from the effects of snake-bites.

It is sincerely to be hoped that the permanganate of potash may justify the encomiums which a Brazilian passes on it, and prove a trusty antidote to the poison of venomous snakes, but before it can be recognised as such, it must be submitted to the ordeal of scientific trial. The facts adduced in the *Times*, entitle it to this trial, but they do not warrant any proclamation of its saving powers at the present time, especially as previous observers who have employed it have found it inefficacious. In respect to antidotes however, everything depends on the precise time and method of administration, and we may hope at least that Dr. Lacerda has hit on a mode of

neutralising snake poison promptly and thoroughly. It remains for him to prove to his scientific brethren that he has done so.

Notes on Current Topics.

Prolonged Meetings.

It was found necessary on Friday last to move an extension of the hours during which the rules provide for the sittings of the Clinical Society, in order to afford an opportunity to Dr. Stephen Mackenzie to read the paper standing in his name for that evening. This course of proceeding, though not usual, is becoming sufficiently frequent to make it desirable that a definite conclusion for future guidance should be arrived at. In this particular case there was good reason for the irregularity, since several country members of the Society had come to town purposely to take part in the discussion on the "Case of Excessively High Temperature" recorded by Dr. Mackenzie. This fact, however, was known beforehand, as was proved by the motion of the President to prolong the meeting for half-an-hour; and, this being so, it would have been much more satisfactory had the paper of particular interest been taken first instead of last. On future similar occasions this should be arranged, as there are many objections to sudden extension of the meeting hours. As it happened, on Friday there remained, at the time when the debate was ultimately adjourned—a quarter to eleven—barely a dozen members in the room, and previously the numbers had rapidly undergone decrease from the moment when it was decided to prolong the sitting. Ten o'clock is sufficiently late for most busy men to remain at a scientific meeting, and many members of the Clinical Society are probably compelled to make their arrangements for attending it with a view to punctual retirement at the regular hour. Not a few, too, are more or less dependent on the train service, so that even a few minutes' delay in closing the meeting may be productive of inconvenience to them. In all ways it would be best to rigidly adhere to the time fixed, and in cases like that which marked Friday's sitting, special measures should be taken to prevent any need for departing from custom. If the rules of the Society demand that communications shall be taken in the order they are received, such alterations as would enable a change to be made in this respect under exceptional circumstances, will be to the advantage of members. In any case, no permanent benefit can result from frequent repetitions of motion to extend the hour of closing.

Prize Question.

THE Prize Committee of the American Medical Association have selected the following question—"What are the special modes of action or therapeutic effects upon the human system of water, quinia, and salicylic acid, when used as antipyretics in the treatment of disease?" The essays must be founded on original experimental and clinical observations, and must be forwarded to the Chairman of the Committee of Award, by January 1, 1883.

Sewage Farming.

ON Wednesday last a large number of gentlemen interested in the question of sewage disposal were conveyed by special train on to the works of the Native Guano Company at Aylesbury for the purpose of inspecting the process of conversion of sewage into manure, and also to view an exhibition of roots and vegetables grown with native guano. The simplicity and efficiency of the A B C process were well seen by the visitors, the whole of its stages by which the incoming sewage from the town of Aylesbury is removed by precipitation with alum and admixed with charcoal and blood, and clear odourless water is sent away by the outlet stream, being illustrated in the regular working of the system. The effectiveness of the manure as an assistant to the growth of crops was plain in the wonderful samples of beet, potatoes, wheat, mangel, vegetables, &c., &c., collected in the exhibition tent, and for which numerous prizes were awarded in competition. Subsequently, a company of about 300 were entertained at luncheon in the grounds, and speeches were delivered on subjects connected with the agricultural interest in special relation to sewage manure, by the Chairman, the Hon. W. F. B. Massey-Mainwaring, Captain Bedford Pim, and others. A very pleasant afternoon was thus spent, and the party returned to town by 6.30 p.m.

Dwellings for the Poor.

MR. PEABODY'S original gift, of half a million sterling for the erection of model lodging-houses, has now become £720,000. This large increase on the capital of the trustees is stated by the trustees' surveyor to be due to the income from the buildings, the occupants of which include all grades of the working-classes. The entire expenses of the management of the trust, according to the same authority, are under £800 per annum. The mortality in these dwellings—calculated upon sixteen years' experience—has been at the rate of 16.7 per 1,000 per annum, while the general death-rate for the whole metropolis during the same period has been 23.4. According to the surveyor's evidence before the Select Committee on Artisans' Dwellings, the death-rate in crowded districts surrounding the buildings may be taken at thirty or forty to the thousand.

This is all very nice, but we are tempted to ask whether it is not a misappropriation of Mr. Peabody's money to provide cheap houses for well-to-do artisans while the really deserving poor are excluded from the benefits of the charity. There is—it strikes us—no merit in making a profit by using the testators' money for a purpose for which it was never intended.

Fractures in Hemiplegia.

IN a communication to the Paris Hospital Society, published in the *Gaz. des Hop.*, Dr. Debove observes that in his practice at the Bicêtre he had frequent occasion to see fractures in the subjects of hemiplegia, these fractures always occurring on the hemiplegic side, there being every reason to believe that changes took place in such cases in the osseous tissue, rendering it fragile. In one case of chronic hemiplegia, he found that not only the fractured bone itself, but all the bones on the same side, had undergone such change.

High Thermometric Readings.

THE question how far high temperatures recorded in cases of disease are to be regarded as trustworthy indications was raised at the Clinical Society of London on Friday evening by Dr. Stephen Mackenzie, who recorded the history of a patient under his care in the London Hospital. This woman had, for a long time, puzzled the authorities of the hospital by registering most unusual temperatures; in one case 120° having been attained. She was, however, watched for a lengthened period with the utmost care, suspicion having been more than once created by the suddenness with which even very considerable differences occurred in the readings, and the final result has been to convince Dr. Mackenzie that his patient was able to raise the index at pleasure. This explanation has been more than once suggested as the probable one for the phenomena in question; and though there are physicians who maintain the reality of at least some recorded instances, the discussion raised on Dr. Mackenzie's paper, and which stands adjourned to a further meeting of the Clinical Society, will do much good by finally settling the question of antecedent probability, even though it fails to definitely determine whether any, or how much, credence is to be attached to individual cases of unusual temperature.

Emigrant Fees.

THE question of remuneration on account of passengers by emigrant ships is one in which no inconsiderable number of the profession is directly interested. A case bearing on this was brought in the City of London Court last week, Mr. Commissioner Kerr presiding, in which the claimant, a medical man, named Confield, sought to recover from Messrs. Jones, Price, and Co., vessel owners, a sum of money alleged to be due on account of attendance on a number of passengers by one of defendant's ships. Plaintiff was surgeon on board, and had entered into an agreement to be paid so much per head for all the persons attended in his official capacity. Defendants held that this had reference only to pilgrims, of whom a considerable number were being carried to Mecca. The agreement specified that "fourpence per head of the total number of pilgrims was to be charged if they did not exceed 100," but Mr. Confield contended that instead of 100 pilgrims only, his remuneration was to be on all on board, thus including coolies also, many of whom were said to be on board the ship but a few hours. Plaintiff averred that he was retained by ship's articles to attend to all the souls on her, and not on pilgrims simply. Mr. Kerr decided to find for the defendants, however, on the ground that the agreement was specific.

The Collective Investigation Committee of the British Medical Association.

THE Collective Investigation Committee of the British Medical Association are about to appoint a secretary, whose salary is to be £200 per annum, with addition for travelling and other expenses. Applications to be made to F. Fowke, Esq., Secretary to the Association, 161A Strand, before November 20.

St. John's Ambulance Association.

THE Metropolitan District Medical Staff of Examiners and Lecturers of the St. John's Ambulance Association entertained Major F. Duncan, R.A., D.C.L., LL.D. (Director of the Ambulance Department, Order of St. John) at dinner on Wednesday, the 26th of October, at Limmer's Hotel, under the presidency of Dr. Sieveking, who was supported by Sir W. MacCormac, Surgeon-Major Baker, Mr. Steel, and with very few exceptions all the lecturers of the metropolitan districts. About twenty gentlemen welcomed Major Duncan and Captain Perrott, the latter with Sir E. Lechmere, and Mr. Furley having been asked to meet the guest of the evening.

The meeting was private, so that the very excellent speeches of the President, and Major Duncan's reply to the toast are unfortunately lost, except to those who had the pleasure of enjoying a feast of reason such as is rarely offered in post-prandial orations. Letters of apology were read by Mr. Steel from Sir E. Lechmere and Mr. Furley, who were unavoidably absent. The popularity which Captain Perrott, the chief Secretary, shares with Major Duncan, was amply shown by the enthusiastic reception he met with, and judging from the cordiality and *bon-homme* which characterised the meeting we shall not be surprised if the hope expressed by Messrs. Cantlie and Crookshank, who were the hon. secretaries, that the dinner may be annual will be borne out in future.

Indian Medical Service Defence Fund.

THE following appeal has been issued by the committee of this fund :—

2 Storey's Gate, St. James's Park, S.W.

The attention of the Committee has been called to rumours that very serious additional changes in the constitution of the Indian Medical Department are imminently impending. It is of the highest importance that all proposals for such a purpose should be carefully criticised, and instant measures adopted to induce the government to refrain from all changes calculated, either to ultimately damage the Public Service, or inflict unnecessary or avoidable hardship and injury on individuals. The Committee are willing to use their best efforts in this direction, but this must necessarily involve a certain amount of expenditure of time and money; the former, the Committee willingly place at the free disposal of their late brother officers, for the latter they regret that they must appeal to the members of the Service themselves. They venture to suggest, if their labours are to be continued, an additional subscription of one guinea, and that each subscriber should use his personal influence to induce those who have not yet subscribed to aid in the good work. Subscriptions may be paid to the Treasurer, the Secretary, or to the nearest branch of the Agra Bank.

The Fund was organised in February 1880. The Executive Committee have held sixty-six meetings; that owing to the organisation eighty petitions have been presented to the House of Commons, and a large quantity of printed matter, setting forth the grievances of the Service, has been distributed to members of Parliament and the public press. The total amount subscribed has been £700, and the balance now remaining (October, 1881) is £87.

The British Medical Association in its Relations with Homœopaths.

THE official record of the recent meeting of the Committee of Council of the Association affords us the following meagre information :—

The President of Council placed before the Committee the question of the relations of the Association to homœopaths.

Resolved unanimously : That the thanks of the Committee of Council be given to the President of Council for his prompt action in obtaining an unequivocal refutation of the charge made against the Committee of Council, that it had suggested to the readers of Addresses in Medicine and Surgery at Ryde the subject of those Addresses; and that it sympathised with the views on consultation with homœopaths therein propounded.

It was moved : That resolutions expressing the views of the Association on the question having been adopted at three meetings of the Association, such resolutions must be binding on the Committee of Council until rescinded by an annual meeting. The Committee of Council, however, does not interpret such views as calling upon it to expel any member of the Association on account of his opinions.

Whereupon an amendment was moved : That By-law 3 be put into force.

By-law 3.—Any member may be expelled from the Association by a resolution of the Committee of Council, if carried by three-fourths of the members present, subject to confirmation by the next annual meeting, and he shall thereupon cease to be a member, and shall not be eligible for re-election. One month's notice of the intention to propose such resolution shall be given to any member affected thereby.

The amendment having been put from the chair, the same was declared to be lost.

The original motion was then put, and declared to be carried *nem. con.*

It will be observed that the resolution adopted by the Committee of Council does not attempt to give expression to any repudiation of homœopathic principles, or of the Bristowe-Hutchinson doctrine of fraternisation with homœopaths. Such an undecided pronouncement is not either reassuring or satisfactory to those who would wish to see the Association purged from "the unclean thing." On the contrary, the adoption of the inaction policy by the Committee gives force to the suspicion that there are those in authority who would like to be allowed to consult with homœopaths if they dare confess as much. At all events, the resolution of the Committee clearly points to the annual meeting of the members as the occasion for deciding the question, and we hope the Association will not fail to take the hint when next it meets.

Poisoning by Nicotine.

It is reported by the Inspectors of Reformatories in Ireland, that during the year 1880, one boy was accidentally poisoned by nicotine. The evidence taken at the inquest on this boy showed that he was given a quantity of tobacco by his mother when she visited him, and that he was poisoned by the excessive use of the narcotic acting on a weak heart.

The Conflict between the Metropolitan Asylums Board and Local Authorities.

At a fully attended meeting of the managers of the Metropolitan Asylums District on Saturday last, Dr. Brewer in the chair, an important resolution was proposed by Mr. Galsworthy and carried unanimously:— "That, having regard to the interlocutory injunction recently granted by the High Court of Justice, restraining the managers from continuing to use the Fulham Hospital, constructed at the expense of the ratepayers generally, for the purpose for which it was established—namely, for metropolitan pauper patients, irrespective of area—and restraining the use of such hospitals to patients within a limited area, as well as to the injunction granted by the Court of Queen's Bench against the use of the Hampstead Hospital, and to the several threats of further legal proceedings, the managers are of opinion that the time has arrived when the General Purposes Committee should seek an interview with the President of the Local Government Board, and ascertain whether the Local Government Board are prepared to take steps, and, if so, what steps, to enable the managers to carry out their duties according to the spirit and intention of the Metropolitan Poor Act, under which the Metropolitan Asylums Board was constituted."

Education in Otolology.

At the last meeting of the Committee of Council of the British Medical Association, a communication was read from the Otolological Subsection passed at the annual meeting held at Ryde as follows:—

"That a committee be appointed to consider, and report on, at the next annual meeting of the Association, the best means of promoting the study of aural surgery, especially in regard to compulsory examination in this subject by the various examining bodies.

"That the committee consist of the chairman and honorary secretaries of this Subsection; and, with their consent, of all the teachers of otology in the United Kingdom, with power to add to their number. (Signed) URBAN PRITCHARD, M.D., F.R.C.S., Chairman of the Subsection; DOUGLAS HEMMING, F.R.C.S.Ed., E. CRESSWELL BABER, M.B., Honorary Secretaries."

It was resolved: "That the application be adopted, and the committee, as asked for, be appointed."

Tincture of Colocynth in Colic.

In the *Louisville Medical News*, Dr. Lowry states that he has found tincture of colocynth, in ten drop doses every 10 minutes for an hour, and hourly afterwards, a prompt remedy for colic, causing rapid expulsion of flatus and other contents of the bowels.

The Revenue for Patent Medicines.

ACCORDING to a return just issued the number of licences to sell patent medicines taken out during the year ending the 31st of March last was 18,754, for which there was paid the sum of £4,688. The revenue derived from stamps for patent medicines during the same time amounted to £139,762, which represented 17,198,442 stamps of different values.

Preparation of Antiseptic Catgut.

Dr. KOCHER, of Berne, having observed the lasting antiseptic effects of *oil of juniper*, employs it now for the preparation of antiseptic catgut. The same author has lately begun to treat silk in the same manner.

Cremation Abroad.

At Copenhagen, at the last meeting of the Society for Cremation, the Secretary-General announced that the Society numbered 1,400 members, among whom were eighty-three distinguished physicians, and many well-known Protestant ministers. The system adopted does not cost more than from 5s. to 7s. each burial. In Italy, as the result of a series of lectures in various capitals of Europe by Dr. Pimi, new societies have been formed, which now number nine in all Italy, and new crematories have been constructed near Rome, Varese, Pavia, Cremona and Leghorn. In Hungary also measures have been taken to establish societies for cremation.

PROFESSOR MAX MULLER was, on Friday last, elected Curator of the Bodleian Library, Oxford, in the room of the late Professor Rolleston, M.D., F.R.S.

THE annual dinner of the past and present students of the National Dental Hospital and College will be held on the 16th November, at the Guildhall Tavern, when the chair will be taken by the Treasurer of the Hospital.

SURGEON-GENERAL SIR ANTHONY D. HOME, K.C.B., V.C., has been selected to succeed Dr. Crawford as principal medical officer in India on the latter officer replacing Sir William Muir as Director-General of the Army Medical Department.

It is stated that the report of the Commission appointed in 1879 to inquire into the sanitary condition of the cemeteries in and around Paris negatives, generally, the popular belief in the noxious influences of great burial places. The composition of the air in the cemeteries, according to M. Schutzenberger, is not distinguishable from that of arable lands.

THE first number of a new periodical, *The Ophthalmic Review*, is announced to appear on November the 1st. It will be a Monthly Record of Ophthalmic Science, and will be edited by Karl Grossmann, M.D., Liverpool, and Priestley Smith, Birmingham. The first two numbers will contain contributions by Mr. Jonathan Hutchinson and Mr. George Critchett.

By arrival of the Royal West India mail steamer, *Medway*, at Plymouth, on Saturday last, we learn of the continued fatal effects of yellow fever in Barbadoes, Demerara, and Trinidad; and that the two medical men despatched from England some weeks since, in response to an appeal for surgical aid from the authorities, have died of this terrible scourge.

THE Admiralty last week issued a circular by which medical officers are relieved from transmitting to the Director-General duplicates or copies of the service cer-

tificates given to them, as to other officers, by the commanding officers of the ships in which they may be serving.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population, were—Bristol 15, Birmingham 16, Leeds 16, Plymouth 16, Wolverhampton 17, Nottingham 17, Bradford Newcastle-on-Tyne 17, Sheffield 20, Sunderland 20, Manchester 20, Brighton 20, Leicester 21, Portsmouth 21, London 21, Glasgow 22, Edinburgh 23, Oldham 25, Salford 25, Liverpool 28, and Hull 29.

FROM diseases of the zymotic class in the large towns last week scarlet fever showed the largest proportional fatality in Hull, Nottingham, Sunderland and Leicester; in Hull 32 more fatal cases of this disease were recorded, making 318 that have occurred since the beginning of July. The 41 deaths from diphtheria included 21 in London, 9 in Glasgow, 5 in Liverpool, and 4 in Portsmouth. The highest death-rate from fever occurred in Brighton, Hull, London and Salford. The fatality of measles showed an increase in Birmingham. Small-pox caused 16 more deaths in London and its outer ring of suburban districts; no fatal case of this disease was recorded in any of the other large towns.

Scotland.

(FROM OUR NORTHERN CORRESPONDENTS.)

EDINBURGH SCHOOL OF MEDICINE.—INTRODUCTORY LECTURE.—This school was opened last week by an introductory lecture by Dr. Alexander Miller. The lecture was a mixture *ad nauseam* of teetotalism, piety, and medical missionary work, and as such seemed to be much enjoyed by a section of the students present, but whether it will lead to any practical result is more than doubtful. There was a large attendance of lecturers and students.

VACANCY IN THE CHAIR OF NATURAL HISTORY UNIVERSITY, EDINBURGH.—Sir Wyville Thompson is about to retire from the above chair which he has held for eleven years. For the last three or four Sessions Sir Wyville has, through ill-health, been unable to lecture, his place being taken by Dr. Alleyne Nicholson, who has more than maintained the credit of the chair. The chair is in the gift of the Crown, and it is to be hoped that the claims of Dr. Nicholson will not be overlooked. It was only last Session that a magnificent testimonial was presented by the students to Dr. Nicholson. Dr. Nicholson is a most distinguished graduate of the University, and the University cannot afford to again ignore the claims of its graduates as was lately the case with Dr. J. Hamilton.

THE UNIVERSITY OF EDINBURGH.—Several of the classes were opened last week with introductory addresses by the respective professors. The addresses of Professors Grainger, Stewart, and Spencer were largely attended and much appreciated. Professor Greenfield was formally inducted into the chair of Pathology, and then delivered a most telling address on "Pathology, Past and Present." After paying a well deserved compliment to the late Professor Sanders and the former occupants of the chair, Dr. Greenfield went on to point out that the present standpoint of pathologists was a

physiological, or rather biological one, and that a large part of our present knowledge had been gained by experiments on animals. Speaking in this connection of the recently published experiments of Pasteur on splenic fever, carried out at the expense, and with the active encouragement of the French government, he claimed priority of this discovery for England, inasmuch as these experiments only confirmed the results of inquiries which he had conducted at the expense of a private society, and in the face of difficulties created by the law, and which results he had published more than a year before. Dr. Greenfield's address made a profound impression on the students, and it is to be hoped that the feeling engendered by the disappointment experienced on the non-election of Dr. J. Hamilton will be set at rest, and that both students and professor will see their way to work amicably together. Dr. Greenfield has certainly the whole matter in his own hands.

EDINBURGH ROYAL (DICKS) VETERINARY COLLEGE.—Professor Walley, of the above college, delivered last Wednesday in the City Council Chamber an able address on the important work which had been done during the last year, tracing also the rise of veterinary science and the establishment of the Royal College of Veterinary Surgeons. Councillor Russell made some remarks at the end of the address on the absurdity of having to ask the government to allow them to vaccinate a calf, yet compelled them to vaccinate children.

HEALTH OF EDINBURGH.—For the week ending with Saturday the 22nd ult. the deaths in Edinburgh amounted to 98, giving a death-rate of 22 per 1,000. There were 8 deaths from zymotic diseases, of which 6 occurred in the new, and 2 in the old town.

PROFESSOR RUTHERFORD AND THE ANTI-VIVISECTION CRUSADE.—In opening the class on Friday last of the Institutes of Medicine in Edinburgh University, Professor Rutherford took as the subject of his introductory lecture the circulation of the blood, with special reference to the discoveries attained by vivisection. By much speaking the anti-vivisectionists had been heard of late, and had succeeded in making some intelligent persons believe their false report. It seemed that physicians must no longer trust the common sense of the people to see that they were being misled by the enemies of science. They must provide the public with a true account of the manner in which physiological discoveries were arrived at. The circulation of the blood might be taken as a typical case. Harvey had himself stated that it was by vivisection that he had discovered the motions and uses of the heart. He was the greatest vivisector this country had ever known. Harvey was followed in the same strain by the Rev. Stephen Hailes. If he had lived and been asked to conduct an anti-vivisection prayer meeting—he (Professor Rutherford) was sure he would have felt no little sadness at the strange shortsightedness of some of his fellow-Christians. Hunter's experiments on living animals had led him to revolutionise the treatment of aneurism. Professor Rutherford then particularised several discoveries affecting the action of the nervous system in its relation to the heart, which had been made by experiments on living animals, and concluded by saying that he was convinced that if unbiassed minds would only consider what had actually been achieved for medical science by experiments on living animals they would not fail to see the necessity for carrying on in the future that kind of research which had yielded so much fruit in the past.

SELF-SUPPORTING PROVIDENT DISPENSARIES.—Writing to the *British Medical Journal* (Oct. 29th, 1881), Dr. Hey-

wood Smith remarks regarding hospital and dispensary practice, "We have been striving to establish on a proper footing, and to recommend to the profession, provident dispensaries, where advice, such as we have referred to (for that class which intervenes between the well-to-do and the poor, while at the same time retaining their self-respect) could be procurable for a small payment by the artisan class; and I would suggest, with a view of carrying out this principle to its widest extent, that the general hospitals, and especially in their special departments, should set apart some time on two days of the week, when artisans could come and get advice for a small payment. If this plan were inaugurated and carried on by the large hospitals, it would go a great way towards maintaining an independent spirit among that class, and would merit their deserved thanks." The Glasgow Public Dispensary was originated entirely on those lines. Advice and medicine are given on special subjects for a small payment to those able to pay the small sum demanded, while they are entirely gratuitous to the extreme poor. Advantage is largely taken of this privilege by the artisan class, and while affording experience alone (as the institution is still in debt) to the medical attendants, much benefit is conferred on the class frequenting the dispensary. It is desired to make it subserve the instruction of students, and should encouragement be afforded, the medical officers are anxious to deliver courses of lectures on the official subjects treated. Such an attempt deserves well of the community, and we trust that adequate support will be forthcoming, to carry on the work satisfactorily.

THE IRISH COLLEGE OF SURGEONS.

THE vacancy in the Council of the College caused by the death of Dr. McOlinlock, is the object of much competition amongst the Fellows. Mr. Butcher, Dr. Nixon, of Mercer's Hospital, Mr. Baker, Dr. Kendal Franks, of the Adelaide Hospital, and Dr. William Carte, of the Royal Hospital, Kilmainham, issued cards announcing their candidature; but as Mr. Butcher is understood to have been adopted as the representative of the party who are striving for improvement in medical education, we believe that Mr. Baker will reserve his candidature until the general election in June. We are not yet in a position to say which of the other candidates will go to the poll.]

OPHTHALMIC TEACHING IN DUBLIN.

AN adjourned meeting of hospital surgeons was held on Saturday last in the Irish College of Physicians to consider the question of clinical ophthalmology and the fees to be charged for instruction in that subject. It will be recollected that the arrangement which had been entered into some years ago that fees should be equal in all hospitals had been broken through by certain hospitals advertising that they would grant ophthalmic certificates free of charge; the meeting to which we refer was therefore called together for the purpose of restoring unanimity if possible. We understand that after some debate the representatives of the hospitals in question yielded, and an understanding was arrived at that a fee should be charged in all cases.

This decision deserves approval, because it may be interpreted to mean that in future ophthalmic teaching—being paid for—will be genuine, and that the requisite certificate will not be simply one of the shams which often represent teaching in other subjects.

Correspondence.

CONSULTATION WITH HOMŒOPATHS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am sorry to find by your paper of this date that my scientific and most laborious friend, Dr. Dudgeon, has found Mr. Lister unwilling to assist him with his surgical skill.

Ever since my letter appeared in the *Lancet*, three years ago, I have found no difficulty in obtaining, not only surgical, but medical, assistance from the first men in the profession.

In that letter I maintained with Hippocrates, that "some diseases were best treated by similars and some by contraries," and that, therefore, I was not a homœopath but a physician availing myself of any method of cure which seemed to me to be best for my patients.

That the law of similars is a most invaluable guide to the selection of medicines in a very large number of diseases seems to me absolutely certain, and that a continually increasing number of rising young physicians are now availing themselves of this law as a guide in the treatment of disease every one knows.

Very lately I had a letter from the most esteemed and venerated medical authority in Great Britain admitting this.

By this week's *Medical Press* I am sorry to find that medical men in the neighbourhood of Leighton Buzzard are still determined not to consult with homœopaths, although their *confrères* in the north-west of England have declared their willingness to admit any upright medical man to professional fellowship, whatever his views on therapeutics may be; and surely, as medicine is not a fixed science but a progressive art, it is only common sense to seek information regarding this art from all honest and thoughtful men of experience.

It is continually asserted that consultation with homœopaths is an absurdity as there is no common ground to stand on.

As one who has considerable experience of such consultations, I may be permitted to explain how this opinion is in error.

1. Consultations are held generally more to satisfy anxious relatives than in the hope of obtaining new light,

2. Consultations are held for the purposes of diagnosis, but especially for prognosis.

3. The medical substance sought for is the last and least important factor in a consultation.

Such being the case I have always found that, by a little mutual forbearance a medical substance was agreed upon without any difficulty, on the understanding that it was to be continued or given up, in accordance with the opinion of the medical man in charge of the case, after due experiment.

So long as medical men are kindly and honest, and equally desire, beyond all things, the good of the patient, there seems to me no difficulty in consultations between those holding various therapeutic theories.

I am, yours, &c.,

12 Gt. Cumberland pl., W.

GEORGE WYLD, M.D.

Oct. 26, 1881.

Obituary.

DR. HAYDEN, DUBLIN.

THE hope of the ultimate recovery of this distinguished physician, which arose a fortnight since, after an extraordinary rally made by him at the point of death, has, we regret to say, proved illusory, and on Sunday morning last death ensued.

Dr. Hayden was the son of the late John Hayden, Esq., of Parson's Hill, near Fethard, county Tipperary. At an early age he became the pupil of his relative, the late Dr. Hayden, of Harcourt Street, and soon after obtaining his degree of surgeon, in the year 1850, he was elected Professor of Anatomy and Physiology in the Peter Street School of Medicine, where he very rapidly obtained distinction as a laborious teacher. On the establishment of the Catholic University, Cardinal Newman, then the newly-appointed Rector, offered him the Professorship, which he held to the time of his death. He was an ex-Fellow of the College of Surgeons, a Fellow of the College of Physicians of the year 1867, of which institution he was lately Vice-President, and would this year have been President but for his lamented illness. He was also a member of the Senate of the Royal University, and Physician to the Mater Misericordiarum Hospital.

His first anatomical work was a paper on the yellow spot of Sommering, which appeared in the *Atlantic* in 1858, but he had previously published in the *Dublin Quarterly* communications on hydatid and on a method of microscopic measurement. He contributed to this journal in 1866 some very valuable clinical lectures on heart disease, which formed the groundwork for his well-known and admirable monograph on these diseases published in 1875. As a physician Dr. Hayden was very highly esteemed, and his services as a consultant were in constant requisition. In his profession he had no enemies, although he never hesitated to have and to express opinions in disputed questions. He was one of the few who never condescended to professional sharp practice in any form, and who preferred his

honour as a physician and a gentleman to the fees which he might have earned by a less conscientious method of doing business, and his memory is, therefore, universally respected, and his death deeply regretted.

Royal College of Physicians of London.—The following gentlemen, having passed the required examination, were admitted Members of the College, on October 27th:—

Ranking, John Ebenezer, M.D. Oxford, Tunbridge Wells.
Sainsbury, Harrington, M.D. London, 21 Huntley Street, W.O.
Springthorpe, John William, M.B. Melbourne, 49 Manor Park, S.E.
Willcocks, Frederick, M.D. London, 52 Scarsdale Villas, W.

The following Candidates obtained the Licentiatehips on October 27th:—

Bickle, Leonard Watkins, 7 Albert Square, S.W.
Clowes, Herbert Alfred, M.B. Durham, Guy's Hospital, S.E.
Dawson, Rankine, 48 Crosier Street, S.E.
Drysdale, Alfred Edgar, 3 Stamford Road, W.
East, Frederick William, M.B. Durham, 2 Clapton Square, E.
Foley, James Leslie, M.D. Montreal, 17 Horton Road, E.
Gubbin, George Frederick, Westminster Hospital, S.W.
James, Charles Alfred, Dispensary, Stoke Newington, N.
Jennings, Charles Ererton, London Hospital, E.
Macnamara, James Thomas, 19 Paris Road, S.E.
Mark, Leonard Portal, 11 Queen Anne Street, W.
Martin, John Michael Harding, M.D. Brussels, Blackburn.
Miller, Herbert Percy, 86 Stoke Newington Road, N.
Palmer, John, Middlesex Hospital, W.
Ross, James, M.D. McGill, 48 Crosier Street, S.E.
Shearman, Percy Edward, 6 Grove, South Wimbledon.
Twynam, George, 18 Blandford Square, W.
Usher, John Edward, M.D. New York, 89 Argyll Square, W.C.

NOTICES TO CORRESPONDENTS.

DR. ROEBUCK (Leeds).—With pleasure; we have directed our Publisher to send you the necessary wood-cuts.

SCRIPTOR.—We shall be very happy to consider the communication, and if it should prove unsuitable you may rely on its being returned. Unless specially requested, we do not return unused M.S., because to do so would entail considerable expense and labour. The letter is marked for early insertion.

DUBTANS.—We must repeat the reply previously given to you. While sorry for the dilemma you are in, we cannot help thinking you are chiefly to blame.

DR. FRASER.—You are scarcely correct in your surmise, since a public retraction has already been made of the expression you refer to. Our interest in the matter is, that of every professional man anxious for the dignity of medicine. How this will be benefited by a prolongation of the discussion we are at a loss to see.

MR. M. H. J.—More suitable for our advertising columns than for editorial reference.

INTEGRITY.—How, indeed! We see no course open to honest men but that of immediate severance from a body which can tolerate open fraud of the most unblushing description. Thanks for your offer; we have already considered the advisability of such a step, and possibly we may take it immediately.

DR. GORDON.—Many thanks; duly received, and marked for early insertion.

J. H. D.—Consult the "System of Medicine," edited by Dr. Russell Reynolds. It treats the subject more concisely than, and yet equally satisfactorily as, Ziemssen's. If you wish special references, and will write to us again, we will furnish you with them by post.

DR. JOHN McDUGAL (Glasgow).—Your lecture "On the Intimate Nature of Zymotic Poison" is marked for early insertion.

THE HOWARD MEDAL.—The subject selected for competition for the "Howard Medal" (1882), given by the Statistical Society of London, is: "On the State of the Prisons of England and Wales in the Eighteenth Century, and its influence on the Severity and Spread of Small-pox among the English population at that period." The Essays also to present a comparison of the Mortality by Small-pox among the prison population of England and Wales during the Eighteenth Century, with the mortality from the same cause during the last twenty years. In addition to the medal, the Council have again decided to grant the sum of £20 to the writer who may gain the "Howard Medal" in November, 1882. The Essays to be sent in on or before 30th June, 1882.

DR. RUTHERFORD.—If possible in our next.

THE CAMBRIDGE DEGREES.—Professor Annibering requests us to announce that the examinations for the degrees of M.B. and M.C. will begin on Tuesday, December 12. Candidates for the degree of M.B. are requested to send their names to the prolectors of their several colleges on or before Saturday, November 26th. The certificates of candidates for the degree of M.B. are to be sent to the Secretary; and the names and certificates of candidates for the degree of M.C. to the Regius Professor of Physic, Dr. Paget, Cambridge, on or before December 3rd.

MR. C. WILKES.—Interesting, very.

MISS B. R.—We are sorry that circumstances prevent us taking the matter up just now.

MR. THOMAS.—1. Either of the physicians named are competent to take your case in hand. 2. We have never heard it stated that they are extravagant as regards fees, which in this, as in every other instance, depends upon the nature of the case, the attendance required, and the reputation of the attendant.

MR. BURDETT.—We think you have just cause for complaint, and owing to a slight clerical error in your tables, Mr. Blair, of the Leeds Infirmary, should have seized the occasion to make certain statements which he must have known were not warranted by facts.

DR. D. CAMPBELL BLACK.—Your interesting "Notes on Spanish Hospitals from a recent Visit" will appear in our next. Proof shall be sent you in due course as requested.

DR. S. L. M. is thanked for the information which he will see has been utilised in another column.

A SECOND YEARS' MAN.—The three leading text-books are all good and reliable; as you profess a preference for one, you will be quite safe in purchasing it.

MR. W. PARKER.—Regret we cannot reproduce your communication as we totally disagree with the whole tenour of it. The treatment of lunacy with the aid of "artificial gastric juice" may appear satisfactory to your mind, but we fail to see the connection. Further, we could hardly be expected to publish a communication containing the statement that you "cured every one of a hundred cases of cholera with artificial gastric juice when a neighbouring practitioner had forty deaths in the same time."

THE SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.—This (Wednesday) evening, at 8, Dr. J. Matthews Duncan, "On Shortness of the Cord as a Cause of Obstruction to the Natural Progress of Labour."—Mr. N. W. Jastreban (St. Petersburg), "On the Normal and Pathological Anatomy of the Ganglion Cervicale Uteri."

HARVEIAN SOCIETY.—Thursday, Nov. 3rd, at 8.30 p.m., Mr. Edmund Owen, "On the Treatment of Joint Affections in Childhood."
BERKELEY SOCIETY (St. Bartholomew's Hospital).—Thursday, Nov. 3rd, Mr. Macready will introduce a discussion on "The Arterial Hemorrhage."

Vacancies.

Birmingham General Dispensary.—Resident Surgeon. Application to the Secretary on or before Nov. 15.

Bristol General Hospital.—House Surgeon. Applications to the Secretary on or before Nov. 5.

Drogheda Union, Termonfecken Dispensary.—Medical Officer. Salary, £110, and £30 as Medical Officer of Health. Election, Nov. 3.
East Sussex, Hastings, and St. Leonard's Infirmary, Hastings.—Assistant Surgeon. Applications to the Secretary not later than Nov. 11.
Monmouth Union (Wales).—District Medical Officer. Salary, £24, with the usual extra fees. Applications to the Clerk of the Union by Nov. 4.

Royal Picnic Dispensary, 104 Buckingham Palace Road, W.—Medical Officer. Candidates must reside in the district. Applications to the Secretary on or before Nov. 7.

South Devon Hospital.—House Surgeon. Salary, £20, with board. Applications to the Hon. Sec. at the Hospital, Plymouth, by Nov. 7.

Appointments.

ALEXANDER, J. A., L.F.P.S. Glasg., Medical Officer for Knocknashan Dispensary District of the Lisburn Union.

BOOBYER, P., M.R.C.S., Assistant House Accoucheur to King's College Hospital.

CHITTY, A. G., M.B.C.S., Medical Officer for the Berry Pomeroy District of the Totnes Union.

CHRISTIE, J. W. S., L.R.C.P., &c., Assistant Medical Officer to the County Asylum, Stafford.

CROOKSHANK, E. M., M.R.C.S., Assistant House Surgeon to King's College Hospital.

GEORGE, J. W., M.R.C.S., Medical Officer for the Fifth District of the Upton-upon-Severn Union.

WILLIAMS, T. H., L.R.C.P. Ed., Senior Medical Assistant to the Glasgow Town Hospital and Asylum.

Births.

BORTHISTLE.—Oct. 18, at Merrion Lodge, Clonsavan, co. Wexford, the wife of Dr. E. Borthistle, of a daughter.

CARMICHAEL.—Oct. 24, at Pollokshields, Glasgow, the wife of Dr. D. Carmichael, of a daughter, stillborn.

FISHER.—Oct. 27, at Falmouth, the wife of James W. Fisher, M.D., Staff Surgeon Royal Navy, of a daughter.

WEBB.—Oct. 23, at Kingsbridge, South Devon, the wife of W. H. Webb, M.R.C.S., of a daughter.

Marriages.

BOOKER-HACKETT.—Oct. 20, William A. Booker, M.D., of Clonsavan, co. Meath, to Jane Henrietta, younger daughter of Thomas Hackett, Esq., of Castle Armistrong, King's Country.

FULLER-BIRKETT.—Oct. 25, at the Parish Church, Ramsgate, Thomas Warburton Fuller, M.B. Lond., to Florence, only surviving daughter of the late George Birkett, M.D., of Stoke Newington.

Deaths.

DAVIDSON.—Oct. 23, at Coventry, Ellen Deane, wife of Charles Davidson, M.D., in her 80th year.

GARNEYS.—Oct. 21, at Repton, William Garneys, M.R.C.S., aged 64.

GREENHOW.—Oct. 25, at Newton Hall, Pottennewton, Leeds, T. M. Greenhow, M.D., F.R.C.S., in his 90th year.

HARMER.—Oct. 19, William Harmer, for more than forty years Proprietor and Resident Superintendent of the North Grove House Asylum at Hawkhurst, in his 74th year.

HAYDEN.—Oct. 30, at 18 Merrion Square North, Dublin, Dr. Thomas Hayden, Fellow of the College of Physicians, and Professor of the Catholic University.

The Medical Press & Circular.

REMARKS ON DISSOLUTION OF THE NERVOUS SYSTEM, AS EXEMPLIFIED BY CERTAIN POST-EPILEPTIC CONDITIONS.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P., F.R.S., Physician to the London Hospital, and to the National Hospital for the Epileptic and Paralysed.

(Continued from page 382.)

SECTION XV.—Difference between the Negative and Positive Elements.

The negative symptoms are directly caused, answer to exhaustion produced straightway by the epileptic discharge. The positive symptoms are indirectly caused, or, it is better to say, are "permitted;" they answer to increased activity of lower nervous arrangements, uncontrolled by their now exhausted higher.

Let us, partly recapitulating, state the stages of the whole process. 1. First, there is an "epileptic discharge," that is to say, a sudden and excessive discharge of certain nervous arrangements, the cells of which are abnormally highly unstable. These unstable cells are likened to a fulminate. This we call a primary discharge. According to quantity of energy liberated, and rate of its liberation (Section XIII.), is the width and depth of spreading in—discharges of—healthy (i.e., normally unstable), nervous arrangements, collateral and lower; these latter discharges we call secondary discharges. 2. When the epileptic discharges are over the cells discharged (those secondarily as well as primarily discharged) with the associated nerve fibres, also engaged in the paroxysm, remain temporarily exhausted. The exhaustion of them is physically the negative element, answering to what is psychically negative affection of consciousness; the positive element, physically, is over-activity of next lower nervous arrangements, which the epileptic discharge had not reached, and answers to what, in the first degree, is psychically the "dreamy state." (See Section XIV.)

Observe the over-activity during the epileptic discharge is excessive, and, therefore, leaves exhaustion; the over-activity in the positive elements, on the contrary, is only an hyper-normal discharge from "loss of control." In

both there are discharges, but they differ enormously in degree. (a)

As the distinction may not seem very definite, we add that the epileptic discharge is supposed to be analogous to that induced by strychnia poisoning; the discharges during the positive element are supposed to be analogous to those of the lower segment of the spinal cord of an animal after cutting the cord across, there is increased excitability of the lower segment.

SECTION XVI.—Two Aspects of the Negative Element.

Thus we look at the negative element from two points of view. It is, in itself, so much loss; it is for the next lower nervous arrangements a "loss of control."

The lower nervous arrangements are not "goaded on," but are "let go," as the heart is "let go," on cutting the pneumogastric nerve; or, as the lower parts of the frog's cord are when the higher parts are practically removed by a section of the cord.

An illustration may make the above clearer. Were the highest governing people in this country suddenly destroyed, we should have to lament the loss of their offices; the loss of them is the analogue of our post-epileptic patient's negative condition. But we should also have to lament the now permitted anarchy of the now ungoverned people consequent on that loss; the anarchy is the analogue of our patient's positive condition.

So far in this Section we are assuming that the positive element is hyper-positive—that the discharges are hyper-normal. But in Section XIII. we admitted that when "control" is slowly removed the positive condition may be normal in degree, or nearly so; and that the actions may be almost normal in rate, but more general than in

(a) After healthy nervous discharges there is, of course, some degree of temporary exhaustion of the parts discharged, although the word exhaustion, from its ordinary associations, is too strong a word. Negative after images are proofs of degrees of exhaustion a little more than normal. When after looking for some time at a brightly coloured object, we have before our eyes the complementary colour, there is evidently a duplex visual condition, negative and positive; we are blind to the colour of the object we had looked at, so far negative, and we have, positive, independently of anything external, the complementary colour—have it if we go into a dark room; the condition of nervous element for the complementary colour is evidently hyper-positive.

health. I suppose that if, in this country, the highest governing people were slowly removed, the "positive condition" of the rest of the country would not be, or would be only slightly, anarchical. The lower governing bodies would, being then highest, gradually become efficient substitutes for general purposes.

SECTION XVII.—*Two Aspects of the Positive Element.*

We have also to look at the positive element from two points of view. There is the result of what for brevity we may call the "permitted" over-energising of the now uncontrolled and thus over-active nervous arrangements. The outcome of this is the survival of the fittest states in what is left of the nervous system. (The survival of the fittest is the law both of healthy and of morbid mentation and of the concomitant cerebration). But there is more to be said. The over-activity of the nervous arrangements in question is, at the same time, a condition of them to be more influenced by the environment (a), from peripheral parts of the body, or from lowest or lower sensory centres. Just as the activity of a frog's spinal cord below a level of section—a part now uncontrolled—is so increased that a touch on the animal's foot produces abnormally vigorous movements of its leg, so I presume that in the several post-epileptic degrees the now uncontrolled and over-excitable nervous arrangements are more and more easily influenced by impulses coming to them.

What we called the "survival of the fittest" is here the resultant of two factors; (1), of permitted activity of what is already organised in what is left of the patient, and of (2) the influence of external things, or peripheral conditions interfering with, modifying, that activity of that already organised. Moreover, a more elaborate state is produced. Thus,—to take an illustration from a case outside our proper subject—in the "reduced" brain of a drunkard, intra-ocular bodies, which would give rise to what are called muscæ before his eyes were his brain healthy, develop elaborate nervous states; there is "projection" of more compound images; the patient "sees mice, &c." Speaking very loosely, the muscæ "turn into" mice, &c.

SECTION XVIII.—*Two Aspects of the Positive Condition (continued).—Illusions.*

Later on we shall give illustrations from certain post-epileptic states. It is now more simple to illustrate the principle stated in the last section by other cases of insanity. The best plan will be to state more fully the view I take of illusions. By an illusion I mean what would popularly be called mistaking a thing for something else, as in the instance from the drunkard's case; another instance is taking a coat, thrown partly on the seat, and partly over the back of a chair, to be a man sitting on the chair. I do not believe that disease ever directly "causes" illusions, or any other elaborate positive mental states, although no doubt it indirectly causes them. I believe that disease destroys or places *hors de combat* (b), certain nervous elements or regions of the highest centres, and that not only illusions, but all positive mental symptoms (except "crude sensations"), are the outcome of activity of lower non-diseased nervous arrangements of these highest centres. The disease—the pathological change—causes negative functional states, or places elements of the nervous system, *hors de combat*; these negative physical conditions answer to negative mental states. A delirious patient does not "see a rat" "by aid" of diseased "structures," any more than an aphasic says "no," or swears "by aid" of the softened part of his brain.

(a) The "influence of the environment" is really that it induces a "local bodily state," a state of our periphery. A lower sensory centre is one which represents the periphery. The three states, mentioned in the text, are fundamentally of one kind, in so far as they lead to changes in the highest centres.

(b) Perhaps the reader wonders why I do not say "loss of function," instead of using the expression "*hors de combat*." I avoid the expression "loss of function," because I believe that elaborate psychical states cease not only during loss of function, say during post-epileptic exhaustion, but during very excessive function also, say excessive nervous discharges in epilepsy proper; during such discharges there arise only "crude sensations."

All illusions, which are positive mental states, imply of necessity some accompanying negative mental states, answering to what are physically nervous elements *hors de combat* from disease. Manifestly the drunkard spoken of, who "sees a rat," does not "see a musca." The mental condition is obviously duplex, negative and positive, and so, of course, the correlative physical condition is duplex, negative, and positive.

Speaking only now of illusions, I believe them to be the psychical side of what are particular elaborate states in healthy nervous arrangements (although in permitted over-activity from loss of control), produced by peripheral excitations (ento- or epi-peripheral), often very simple ones, or by simple external conditions. Let me illustrate this dictum. I first, however, ask the reader again to bear in mind that all mental states, healthy or morbid, are the survival of the then fittest states during activity of what are the highest arrangements at the time. When produced by a peripheral excitation, &c. (see Section xvii), illusions are the termination of a struggle starting "from below;" they "appear at the top;" in dissolution the nervous system left is "shallower;" "the top" is then lower than normal; there is less of the person, less of the highest nervous arrangements.

We may, with propriety at a clinical conference, say that cerebral atrophy is the cause of a patient's illusions; it would be pedantic to object to the phrase. In scientific exposition we must be as rigidly exact as we can in our use of terms, and then we must say that cerebral atrophy cannot possibly be the cause of a patient's illusions. "Atrophied nerve tissue" is not nerve tissue at all; it is functionally just nothing, and cannot be the cause of anything positive; the positive mental symptoms, the illusions, arise during activity induced in non-atrophic, in healthy, nervous elements of what is left of the patient, at least, in elements capable of functioning. They cannot arise during activity of the atrophied elements, of what is lost of him; that is to say, they do not arise "during activity of nothing." All this sounds like mere barren truisms. But I confidently believe that the distinction is very frequently disregarded.

In the foregoing we are repeating the principle stated and illustrated by a case of "defect of speech," in Section XI, as to duplex symptomatology. Atrophy of the brain is no more the cause of illusions than softening of the brain in the case of an aphasic is the cause of his wrong utterances. (a)

The softening answers to the patient's inability to utter the right words; the atrophy answers to the patient's inability to see things as they are, that is, as he used to see them before the atrophy began. If a man takes a felt hat lying on the floor to be a black cat, it is as certain that, negatively, he does not see the felt hat, as that, positively, he does see a black cat; indeed, this is given in the expression, "he mistakes a felt hat for a black cat." To say that the patient cannot really see a black cat, "because there is not one," is of no avail. His nervous system is not ours; nor if it were quite like ours when he was well, is it so when disease has occurred in it; he sees a black cat; we see a felt hat. The thing outside *rouses in him* the image of a black cat; it *rouses in us* (and in him, too, on his recovery), the image of a felt hat.

There are similar illusions in some peculiar healthy states. In reverie, "we see faces in the fire." There is

(a) Let me instance a stronger case than that given in Section XI. A man after destruction by softening of some part of the left cerebral hemisphere, can only say "no." No one would declare that the destruction of so much of his brain was the cause of his saying "no;" it is the cause of his inability to say anything else. This is obvious enough, but the destination is not thought of in cases of "defect of speech." For the misinterpretation of these cases, popular psychology is to blame. The patient is sometimes said to have "loss of memory for words." If this covers his negative condition, his not saying the right words; it leaves out of consideration his positive condition, his saying the wrong words. I believe this psychologico-materialistic nomenclature is supposed to be justified, because very often the patient quickly and spontaneously corrects his mistakes.

here to use ophthalmological metaphor, temporary relaxation of object consciousness, or speaking more simply, we are dim to our surroundings, to the most special of them I mean. We do not see the cracks and marks in the burning coals. The cracks and marks do not produce the images of cracks and marks in us; they produce faces in us. (a) A simple thing acting on a person who has undergone such temporary normal dissolution, produces in him as it does in those whose dissolution is morbid, more elaborate nervous states; there is greater "irradiation," &c., with concomitant more elaborate psychical states. On the cessation of the reverie, the cracks and marks act just as much, but our very highest nervous arrangements being again in activity, the currents developed by the cracks and marks do not "stay" in the lower nervous arrangements, and spread widely therein, but pass quickly upwards."

Numerous illustrations of the above stated dictum are given in books on dreams. Sleep is a normal dissolution; the dream is analogous to our positive element.

It must not be forgotten that, as has been illustrated, a compound effect is produced. It is not that an external thing, or peripheral condition (the condition of the organism in each is, anatomically speaking, a peripheral one) simply produces a more intense effect, but that it produces also a more elaborate effect.

If the view above taken be correct, it is an error to suppose there to be necessarily particular localities of the brain diseased in any cases of illusions; that, for an example, there is necessarily disease of the auditory (cerebral) centre in cases of "hearing voices." (b)

There is, I submit, some negative condition widespread in the highest nervous arrangements in cases of illusions, and these positive mental states arise during great irradiations in the nervous arrangements left intact.

Visual illusions are commoner than others, partly because vision is the most special, most representative, sense; the nervous highest arrangements concerned will be less organised; they will "give out" sooner under conditions affecting the highest centres uniformly. I think that essentially the same holds good of what are called hallucinations. I believe that they are often really illusions, arising from external conditions, from morbid states of peripheral parts, or of lower sensory centres. They result from irritations propagated up to the highest centres, that is, to the uncontrolled, and thus over-ready-to-act, nervous arrangements left in these centres. When there is general "reduction" of brain, that one patient always "hears voices," and that another always has visions, may depend, I think, on irritations starting from the eyes or from the ear, or from the lowest sensory centres more directly representing those parts, and not necessarily on the cerebral visual, or auditory centres in particular being diseased; the disease is of some nervous arrangements throughout the highest centres, of those centres which represent all parts of the body. Similarly we do not suppose the physiological condition of the cerebrum to be different when a person dreams that he has a spoon in his throat, and on another night, that a cat is biting his finger; we infer that in the former he has a sore throat, and in the latter that he has cramp of the finger. The local bodily states produce elaborate states in the nervous arrangements of the highest centres left capable of functioning, or of being easily roused to function in this normal dissolution.

Yet I do not deny, but affirm, that particular parts of the highest centres represent more especially particular parts of the body, say the eyes or ears. Thus I tacitly admit three factors in the production of the morbid mental states spoken of.

(To be continued.)

THE HISTORY OF DISCOVERIES CONCERNING THE CIRCULATION OF THE BLOOD. (a)

By PROFESSOR RUTHERFORD, M.D., F.R.S.,
Professor of the Institutes of Medicine in the University of Edinburgh.

PROFESSOR RUTHERFORD prefaced his lecture by observing that the beginnings of physiological science were the results, not of curious desire to obtain a knowledge of the workings of the bodily mechanism, but of a necessitous desire to know how its diseased conditions could be understood and cured. Thus it came about that the history of physiology is wrapped up in that of medicine. At the outset when the complex and delicate machinery of the body was unknown, the practice of medicine and surgery was nothing more than a mere groping amidst the darkness of empiricism. By slow degrees the brightening light of advancing science was dispelling that darkness, and placing the practice of medicine upon the sound and firm foundation of well-ascertained facts and logical principles, but there yet remained, and would long remain, many dark places into which light could not be thrown until physiology had advanced far beyond its present standpoint. Going on to speak to the subject of his lecture, he said it had for some time past unfortunately become customary on the part of certain opponents of medical progress to systematically represent that nothing of any value had been learned from experiments on animals. These persons have been heard "because of their much speaking." By the frequent repetition of statements calculated to produce an erroneous impression upon those who had not been educated in biological science, they had succeeded in persuading many intelligent persons to believe their false report. It seemed to him perfectly plain that they must no longer merely trust the common-sense of the public to perceive that they were being systematically misled by the enemies of science. They must trouble themselves more than they had hitherto done to provide the public with a true account of the manner in which important physiological discoveries have been arrived at. He could not, in the course of a lecture, do more than allude to a limited part of physiology, and he had chosen the circulation of the blood, because that was a typical case from which the others might be judged. It was long a prevalent idea among the ancients that the blood of the body was contained in the veins and right side of the heart, while the left side of the heart and arteries were filled with air derived from the lungs, and distributed to all parts of the body to keep it cool. So completely did this idea of blood in the veins occupy the mind of classic writers that even now were anyone on some rhetorical occasion to say—e.g., that Mr. Gladstone had Scottish blood in his arteries, he would be regarded as an iconoclast of classical phraseology. That old erroneous idea resulted from a lack of knowledge regarding the many differences that arose between a dead and a living body. After explaining in detail the erroneous doctrines regarding the circulation of the blood which had continued to hamper the progress of medicine for many centuries, with special reference to the researches and theories of Galen, he observed that undoubtedly the reason why Galen, with all his ingenuity, failed to correct so many errors, was that he was not sufficiently impressed with the necessity for bringing all theories to the touchstone of exact observation or thoughtfully planned experiment. He also referred to the discoveries of Michael, Servetus, Colombo, and others; and gave an account of the life, work, and discoveries of Harvey, with regard to whom he remarked that it was not too much to say that Shakespeare had not done more for English literature than Harvey had done for English medicine. Harvey told them that he sought "by vivisection," and not by a "study of the writings of others, to discover the motions

(a) Abstract of a lecture delivered at the Opening of the Institutes of Medicine, in the University of Edinburgh, on Friday, Oct. 28th.

(a) There is a little thimble-rigging here in saying that the "cracks and marks in the coals" produce faces (certain images) in us. We shall consider this matter later on.

(b) If there were, the "hearing voices" would not result from the disease, but would occur during activity of parts of the centre not diseased. Besides what is called "hearing voices," is something more than hearing particular sounds.

and uses of the heart," that he was at first greatly perplexed when he looked at the moving heart, but that by "daily diligence at vivisection" on a variety of animals "he thought he had obtained the truth," and every physiologist knew that Harvey was the first to give a true account of the heart's movement. Harvey was also the first to give a correct explanation of the pulse. He proved by experiment that the pulse in the arteries was not synchronous with, but succeeded the impulse of the heart, and that the pulse was due to an expansion of the vessels by blood projected into them from the heart, and not to any inherent power of expanding like a pair of bellows, as was commonly supposed. Need he say how great a step was made in the progress of medicine when Harvey experimentally demonstrated the true cause of the pulse? Harvey had also experimentally demolished the old idea that air passed from the lungs into the pulmonary veins, to be mingled with blood in the heart, and distributed through the arteries to the body generally. Every surgeon knew well the importance of this discovery. In many of his operations he carefully guarded against the entrance of air into blood vessels, for he knew that death would inevitably follow the entrance of even a relatively small quantity of air into the veins. With regard to the flow of the blood in the veins, Harvey demonstrated that the blood flowed only towards the heart. He opened the jugular vein in a living animal and found that it ceased to bleed when its cranial aid was compressed, but continued to bleed although its cardiac aid was compressed, proving that the blood flowed in the vein towards the chest and not from it, as Galen had supposed. He experimented on the flow in the veins of the human forearm with a similar result, while in the same way he demonstrated the function of the venous valves. There was much commotion when Harvey proclaimed his doctrines. Many blamed him for his temerity in daring to call in question the doctrines of the ancients. Many denied the truth of what he said, but he was indefatigable in demonstrating his experiments and in devising new ones to carry his case, and he lived to see his doctrine accepted by all. How history repeats itself. Harvey in one of his letters said, "There are some who say I have shown a vain-glorious love of vivisection, and who scoff at the introduction of frogs and serpents, flies, and other lower animals, upon the scene, as a piece of puerile levity, and they do not hesitate to use opprobrious epithets. But to return evil speaking with evil speaking I hold to be unworthy in a philosopher and searcher after truth. I believe I shall do better and more advisedly if I meet so many indications of ill-breeding with the light of faithful and conclusive observation." His detractors did at length grow weary. Even in these days of detraction, he, the greatest vivisector this country had ever known, was treated with respect, and a monument was raised to his memory in his native town. How often it had happened in the history of science that those who could not comprehend the aims and methods of the searcher after scientific truth were all too ready to cast a stone. So it was with one so great as Harvey. His humble followers need not wonder if they fare no better. But while Harvey was saying these things, and wincing a little under the stings of the wasps who buzzed about his ears, there lived at Teddington, on the Thames, the Rev. Stephen Hales, rector of Faringdon, in Hampshire, and minister of Teddington. To him they owed the first measurement of the pressure of blood in arteries and veins. This knowledge was entirely arrived at by experiments on living animals. He introduced a long upright glass tube into one of the larger vessels, and observed the height of the column of blood which the pressure could support. He made many experiments on different animals, and under the varying conditions, and thereby tapped a spring of knowledge which still flowed with new discoveries. In physiology and pathology there was scarcely any subject which required to be more frequently taken into account than the blood pressure. It was like the pulse, a household word to the physiologist. He fancied the Rev. Stephen Hales

would have been greatly gratified could he have seen all that was to flow from his experiments, and he rather wondered what he would have said had he lived until now, and been asked to conduct an anti-vivisection prayer meeting. He was sure he would have felt no little sadness at the strange short-sightedness of some of his fellow-Christians. From Harvey and Hales let them pass to Hunter. John Hunter was a Scotchman, of whom they had reason to be proud. No monument had yet been raised to his memory, but he needed none. The great museum of the Royal College of Surgeons of London, one of the wonders of the scientific world, was his monument. He made many experiments on living animals. The result of one of them led him to revolutionise the treatment of aneurism, that disease of blood vessels, always so dangerous and nearly always deadly before he invented the great operation which bore his name. But how could he possibly recite in an hour an account of the other discoveries regarding the circulation made by vivisection? It was long imagined that the heart was the great source of the heat of the blood. The great phenomenon of fever was an increased production of heat. How could they hope to gain a true theory of heat production in fever if they were still under the delusion that the heart was the great source of heat? Experiments on living animals alone showed that the heart was not a more important source of heat than any other muscle, and that the hottest blood of the body was not in the heart. Their knowledge of the function of the nerves of the heart and blood vessels they owed exclusively to vivisection; and where was there in physiology and pathology a subject of greater importance than the nerves of the heart and blood vessels? Many lectures in future days must be devoted to these great subjects, and then also they should have to state yet other discoveries regarding blood circulation which had been made by vivisection, and he need hardly say many other discoveries regarding other departments of physiology which had been made in the same way. He was convinced that if unbiassed minds would only consider what had actually been achieved for medical science by experiments on living animals, they would not fail to see the necessity for carrying on in the future that kind of research which had yielded so much fruit in the past. He had never been an advocate for the performance of painful experiments for mere demonstration, and in that room they would not witness, and none of their predecessors had witnessed, a single experiment that implied pain. They had been in that matter subjected to very paltry misrepresentations, for the purpose of prejudicing the public mind. He was sure, however, that the great majority of the public gave them credit for doing their best to advance the interest of medical science, and although they might not understand their methods and objects yet he was persuaded that they were disposed to doubt the tales of their opponents, and to give them credit for sincerity, and for a humane pursuit of the knowledge by which all profited daily.

NOTES ON SPANISH HOSPITALS.

By D. CAMPBELL BLACK, M.D., F.F.P. & S.G.

DURING a recent visit to Spain, after having exhausted the sights which first claim the attention of the tourist, and they are emphatically numerous and interesting in the highest degree in Sevilla, turning my attention to matters pertaining more especially to my own profession I sought the "Hospital Central." It was late in the day when I arrived, the hour of professional visit was over, and the sense of repose which the magnificence of the climate imperatively impresses on animate nature, particularly at midday, was manifest in every direction. Knowing by former experience in other parts of Europe that courtesy and kindness are never denied to the foreign physician by his *confères* abroad, I sought the apartments of the resident physician of the hospital, and I confess to having felt a little misgiving when I

found that I evidently disturbed the *siesta* of Dr. Eduardo Fedriani y del Pozo after the performance of his forenoon duties, doubtless glad of shelter from a temperature of not far short of 150° F. in the sun. I explained to him the object of my call, when with a courtesy, not especial to our profession alone, but characteristic of his compatriots, according to my experience, he professed his willingness to guide me over the magnificent hospital of which he was in charge, and show me everything or anything calculated to instruct or interest me. I do myself the pleasure again of acknowledging his courtesy, and the ungrudging spirit in which he received the considerable demand which I made on his patience and time.

The "Hospital Central" of Sevilla is situate in the north-eastern suburbs of the city; an excellent view of it, in the distance, may be obtained from the Giralda, or cathedral tower. It is an immense building, built in 1546, and contains no less than 800 beds. Notwithstanding its great size Dr. Pozo informed me that it is felt inadequate for the requirements of the city with its moderate population of about 120,000. The building is quadrangular in form, and has its main entrance on the southern aspect, which presents a beautiful façade; it is subdivided in its interior by *patios*, or open courts containing luxuriant fruit and other trees—an arrangement admirably calculated to ensure a fresh and sweet atmosphere. The floors of the wards are of marble; the ceilings are arched, and are higher than I have seen in any hospitals, either in this country or abroad. The wards are scrupulously clean, and the patients seem all attended to by sisters of charity, whose delicate and unwearying attention cannot be too highly commended, other considerations notwithstanding. It strikes the stranger as peculiar that in an hospital such as this lunatics of both sexes are to be found, of course, in separate departments. I think it will hardly be doubted that the complete isolation of cases of mental aberration, from ordinary cases of bodily disease, as obtains in this country, is to be desiderated, and that certainly in this direction Spain would do well to follow the example of certain other European countries.

Among the lunatics three cases of erotomania were pointed out to me; and Dr. Pozo informed me that in a case of nymphomania which he showed me, cauterisation had been employed without any beneficial result. Specialism is recognised to the extent that there are separate wards for venereal, skin, and ophthalmic diseases, as also for diseases peculiar to women. Syphilis prevails to a considerable degree in Sevilla, as judged by the number of cases in hospital. I could not discover any severe cases of constitutional disease, a fact which I ascribe to the treatment observed, viz., the general treatment of this country, by perchloride of mercury and iodide of potassium. Ague is a prevalent disease in Sevilla, and many cases of it were in hospital. I was shown a case of double amputation of the upper extremities, one at the shoulder-joint, and the other immediately below the elbow, and the latter, by an unfortunate perversity for modern surgical science presented a beautiful stump, which *healed by the first intention, without carbolic acid!* The patient met with an accident at the railway station a few days before, he was picked up almost lifeless, and dreadfully mangled, notwithstanding which, when I saw him his case was doing well, and I doubt not his progress towards recovery has been uninterrupted. Listerism in its orthodox details of steam engine, smearing of instruments, and disinfection of body, &c., is here unknown. I should think that the magnificent atmosphere of Sevilla must be inimical to these wonder-working spores! Carbolic acid, salicylic acid, boracic acid, &c., are, however, used in the ordinary manner. The surgical instruments, which are extremely well kept, are entirely of French manufacture, and comprise all the modern instruments. In the department for diseases of women my attention was directed to a remarkably extensive case of *nævus*, extending from the pectoral region, over the abdomen, and down to the vulva. At the menstrual period, instead of the usual discharge per

vaginam, blood oozed from the whole of this extensive surface.

Dr. del Pozo properly deplored the too general abandonment of the Latin language, which formerly formed the medium of intercommunication between physicians of all nations. I observed a prudent taciturnity as to the accomplishments, in this respect, of the great bulk of Scotch physicians, in such large centres as the good city of Glasgow. He further expressed the hope, that the day is not far distant when the existence of a common pharmacopœia for Europe will enable medical practitioners to have their prescriptions dispensed in its several countries.

One of the sights of this hospital is its magnificent chapel—certainly, one of the finest in Sevilla, and that is saying a great deal. Its walls are beautifully ornamented with medallions by Machuca, and pictures chiefly by Zurbaran. There is a crucifixion to which a peculiar history attaches, being a copy from one at Rome, said to have been painted by a bishop who sold himself to the "leader of the opposition" in morals, and whose characteristic is the profusion of blood which flows from the wound in the side. Dr. Pozo made the just professional criticism that so much blood was not likely to flow from a contused wound.

The College of Surgeons of Sevilla is situated in one of its finest streets the *Calle de las Armas*. It is a dingy looking old building, with a small library of very much moth-eaten ancient books, chiefly in the Latin, Italian, and Spanish languages. Being quite obsolete, and valuable only on account of their antiquity, these books are evidently enough very rarely looked at. Unlike France, Germany, and Great Britain, Spain produces few medical books. Whether this is significant of learning, and good sense or not, I will not presume to decide. The standard medical works are chiefly translations from other languages. In this building there is a hall of considerable size evidently used for professional meetings, at one end of which there is a raised presidential chair. The walls are adorned with twelve well-painted "portraits." I am afraid I shocked the religious sentiment of the good lady who showed me round, when I inquired whether these were the portraits of famous Spanish doctors. Considerably taken aback she informed me that these were the "twelve apostles." As they lived, now, nearly two thousand years ago, I confess that I did not recognise the resemblance; and to me they certainly looked more like twelve Spanish *litterati* than twelve Jewish fishermen. This is a phase of Spanish social life which strikes the foreigner in visiting public institutions in Spain, hospitals included. The religion of the country obtrudes everywhere. Certainly in hospitals if the cure of the body is, as I believe well and scientifically attended to, that of the soul is not neglected. The *upas-tree* of Spain is widespread. It entwines itself around the human heart wherever it is rendered impressionable by grief, by misfortune, or by doubt; it embraces all ranks, particularly of females from the lowest to the highest, cripples the Spanish intellect, and fetters the progress of chivalrous Spain in the march of nations.

The General Hospital, Granada.—During my sojourn at Granada, I visited the large hospital in the *Calle de San Lazero*. It is in the same style as that at Sevilla; but it seemed to me in a more ruinous condition, and not so well kept. The courts are adorned with paintings of religious subjects, and here again the patients are tenderly nursed by nuns. Medical instruction is given here. At Cordova there is an excellent hospital quite near the celebrated *Mezquita*. I arrived during the hour of visit in the morning, introduced myself to the physician, but as he could not speak French, I had not the pleasure of interchanging opinions with him. With Dr. José Amo, one of the junior physicians, I was more fortunate. I was much struck with the prevalence of chest affections both at Cordova and Granada, when the magnificence of the climate was considered. I am inclined to think that some special cause, such as peculiarity of avocation, must be held accountable for this. Perhaps Dr. Amo of Cor-

dova, or Dr. Pozo of Sevilla, will courteously throw some light on this subject. Its elucidation might be useful in the interests of invalids who might be recommended to Spain, owing to its intellectual or climatic attractions.

I noticed several cases of typhoid fever in the wards at Cordova. The usual home-treatment was pursued, and the usual solemnity and prudent taciturnity as to the *modus medendi* of the remedial agents judiciously observed. In this hospital there are also lunatic wards; as also separate military wards. I had a look at the performance of the preliminary steps of a cataract operation; and was chiefly impressed with the *nonchalance* of the assistants smoking cigarettes, as they looked on, or assisted.

There is no teaching at Cordova. Surely the intellectual sun has set on the natal city of Averroes and Avicenna! As the result of my visit to these hospitals in the three principal cities in the south of Spain, I cannot join in the too frequent, and possibly ignorant, depreciation of Spanish medicine or surgery, and I would impress on any of my professional brethren sojourning in those beautiful, and historically, interesting localities, the pleasure and instruction which a visit to the Spanish hospitals affords, and the polished courtesy with which the stranger is received.

Clinical Records.

ST. MARY'S HOSPITAL.

Two Gall Stones Passed Through an Abdominal Abscess.

Under the care of MR. NORTON.

ELLEN W., married, *et.* 40, had three years ago, suffered from an abscess in the region of the umbilicus, which had continued to discharge up to the time when she presented herself at St. Mary's Hospital. It had occasionally healed up for a short time, but the closure of the wound had been followed by pain necessitating poulticing and warm fomentation, after which it had re-opened. When she applied at St. Mary's Hospital there was an opening about an inch above the umbilicus through which thin pus escaped. A probe was gently inserted and then the finger pressed through the opening in the direction upwards and deeply inwards towards the liver. On the following day a gall stone about the size of an average marble was passed through the wound, and about half an hour afterwards a second stone passed, three-quarters of an inch long by half an inch broad. The wound shortly afterwards healed.

It is to be presumed that the gall stones were formed in the gall bladder; that at the date of the first abscess, three years, or to be more precise, two years and eleven months before the patient presented herself at St. Mary's Hospital. The gall bladder had become attached and the stones had left the gall bladder for the sac of the abscess, where they remained until the sinus was sufficiently dilated for their passage. It was evident that the sinus did not communicate with the gall bladder at the time the patient was seen at St. Mary's, because no bile escaped from the outer wound, so that it is probable that the communication between the sac and the gall bladder was cut off shortly after the escape of the stones from the gall bladder, about the date of the first abscess.

MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.

Brief Notes of Operations.

Under the Care of LAMBERT H. ORMSBY, F.R.C.S.,
Lecturer on Clinical and Operative Surgery.

(For these notes we are indebted to Mr. FRANK CAMPBELL).

OPERATION I.—*Case of Cleft Palate.*—Thomas H., *et.* 18, from co. Cork, was admitted to Meath Hospital, June, 1881, suffering from a congenital fissure of the entire soft palate. He suffered a good deal of inconvenience when swallowing liquids, as the fluid frequently came out through his nose, and soft food of all kinds lodged in the fissure,

besides his manner of speaking with a nasal twang, was most unintelligible.

A week before any operation was performed, the patient was ordered a gargle, containing sixty grains of bromide of potassium to six ounces of water, to be used constantly in the day in order to render the fauces and soft palate less sensitive, and therefore allow more freedom of manipulation of these parts during the operation. On June 18th the operation was performed without any anæsthetic; the patient was placed on the operating table in a semi-recumbent posture, in such a position that good light could enter the mouth, and so display the parts as well as possible. The steps of the operation were as follows:—

1st. Mr. Ormsby having the mouth well kept open by means of a gag, the edges of the cleft at each side were evenly pared and vivified all round.

2nd. Needles, with an eye in the end, and fitted in a good handle, armed with pink thread, were passed through the cleft at one side first, when four double threads at each side were thus introduced exactly opposite to each other.

3rd. The first two loops nearest the angle of the fissure were attached to each other, and then drawn through in order to have one thread through each side of the fissure exactly opposite to each other; the three other pink thread loops were treated in a similar manner.

4th. To the first loop of thread nearest the angle of the fissure, a stout piece of silver suture wire was attached and drawn through the fissure; when this was done the ends of the wire were twisted until the previously cut edges of the fissure came together evenly and perfectly. The remaining pink threads were treated in the same manner with the silver wire, until the entire fissure was brought together. The ends of the twisted sutures were then cut off short; very little bleeding occurred at the time, and none followed subsequent to the operation. The boy was then sent up to his bed, with directions that he should get nothing but liquid nourishment for one week after the operation; he was also cautioned to speak as little as necessary, so as to give as much rest as possible to the soft palate. In ten days the silver sutures were removed, and at the end of a fortnight the fissured parts had nearly altogether united, save one very small hole in centre of palate. The boy's speech, and manner of speaking, was also greatly improved. Mr. Ormsby finding this small aperture touched the edges, with strong nitric acid on the end of a pointed deal stick, after two such applications at intervals of a week, was found to be sufficient to close the opening permanently. At the end of six weeks the boy was discharged from the Hospital.

OPERATION II.—*Removal of a Horny Growth from Lip.*—

Mary C., *et.* 30, admitted 13th June, 1881, suffering from a hard horny growth, springing from centre of lower lip.

History—She does not remember having received any blow; but about a month ago her lip began to get very painful, and she then noticed this tumour growing very rapidly.

Operation performed 22nd June, 1881. A V-shaped incision was made at each side of the tumour in the lip, and the growth thus removed. It was found, however, not to encroach very deeply into the substance of the lip. The incision was then brought together with silk-worm gut sutures, and the woman made a very good recovery, with little or no deformity resulting.

OPERATION III.—*Muco-Gelatinous Polypus of Nose.*—

G. P., *et.* 42, was admitted under the care of Mr. Ormsby on September 3rd, suffering from a large polypus of the nostril.

History—States it had been growing for the last four months, and it always appeared worse in damp weather. Operated on the 7th September. On examination the pedunculated growth was found to be attached to the middle turbinated bone. A wire snare was passed round the pedicle of the tumour, and firmly constricted, and when the wire was tightened, a slight jerk of the hand was given, and the polypoid growth came away without much trouble; smart hæmorrhage followed, which, however, was arrested by cold applications.

OPERATION IV.—*Removal of Internal Piles.*—J. O., *et.* 38, was admitted to Meath Hospital, August 30th, suffering from internal piles. *History*—States he has been suffering from pain and irritation about his lower bowels for the last four years. He suffered from constipated bowels for a long time. He had frequent passage of blood from the bowels; has had a good deal of sitting to do, working at his trade as a saddler.

On examination on asking the patient to force down, a large bunch of inflamed piles were easily discernible; they seemed to affect the entire circumference of the canal. The patient was much annoyed by the passage of a large quantity of bloody viscid mucus; at the other times pure blood was passed in large quantities, particularly when the bowels were very confined. His face and lips presented a very blanched appearance, as if from the loss of blood. The patient's chest was carefully examined, as well as the abdominal viscera, and as there was nothing to contra-indicate operative measures, it was decided to remove the piles. Operation performed on 7th September. The patient having been ordered to sit over hot water an hour before, and having then been placed fully under the influence of ether by means of Ormsby's inhaler. The nates having been well divaricated, and brought well over to the edge of the operating table, as the patient lay on his left side. The piles were fairly protruded, but Mr. Ormsby drew them still further down by means of the ring pile forceps. A needle, armed with a double hempen ligature, was then passed through the base of each pile separately, and tied at each side, having thus deligated all the mucous tumour then apparent. A morphia suppository was then inserted into the rectum, so as to allay pain, and prevent the action of the bowels, all the ligatures, with the strangulated piles, came away in ten days, and the man was discharged to the convalescent home in three weeks, and returned, after a fortnight, perfectly well.

Special.

THE ARMY MEDICAL DEPARTMENT REPORT FOR THE YEAR 1879.

THE Report on the health of the British Army for 1879 is an extremely interesting document. It presents in clearly prepared statistics the rates of sickness, mortality, and invaliding, among the troops, whether occupying stations in the United Kingdom, or serving abroad. To some extent it enables its readers to compare those statistics with similar information having reference to previous years. It thus furnishes them with the means for tracing whatever relation exists between schemes of improved sanitation, reorganisation, administration, and so on, such as have recently been pressed on, and the actual health conditions of the men who fill the ranks of what, until very recently, were called out regiments. Taking the general conditions of the life of a soldier in India as they were in former years, and comparing them with those under which he served in 1879, they absolutely differ from each other in nearly every respect. No doubt such changes as have taken place, have been gradually introduced. For a good many years back they have been in gradual progress, and perhaps in the year under notice, they may, for the purposes of comparison, be looked upon as having been as complete in their manner of working as they are likely to be, until, in their turn, superseded by still further changes. Among the more important of the differences which characterise a soldier's life in India at the present time as compared with former years are these:—A brief period of service in that country instead of one of long duration; the great increase of hill sanitarium to which regiments, men in failing health, convalescents after attacks of illness in the plains, and young delicate recruits, even before they have joined their regiments are sent; all these classes in immensely greater numbers than formerly; the facilities afforded by the transport ships, and taken advantage of to dispatch to England men who became severely ill, and the great development of the system of railways, by which during the period of the year when transports have ceased to run, sick men may be dispatched from the intense heat of the plains to the cool climate of the hills. To this list must be added the extensive and palatial barracks recently erected at a cost of

some millions of pounds sterling; the demolition of buildings, the erection of others; the alterations made as regards surroundings of military barracks and stations; the improvements in water supply; the revolution effected in the system of scavenging; and the many other items included in that very comprehensive term "sanitation,"—the general result being an increase in the military budget for India from eleven to seventeen millions sterling. But there are other improvements connected with the soldiers in our great dependency as in the service generally, which are of importance in relation to what the report before us presents. In former years young medical officers arriving in India joined regiments in which henceforward they were to serve, and there, under the direct superintendence of their senior, learned—as he had done before them—the practical results of experience in the treatment of disease as it occurs in that country. In this way experience becomes accumulative, each medical officer adding his share to the general stock, correcting his theories by clinical observations, and so by means of personal teaching, and ready reference to hospital records, in his turn benefiting his successors as he himself had been indoctrinated. For a considerable number of years back this condition of things has been undergoing a process of destruction. In 1879, and indeed, for some time previous, it had ceased to exist. The report recently published, shows very clearly what, from a medical point of view, have been the results, as far as it is practicable to connect measures with circumstances that appear to lead to them.

The average strength of troops serving in the Bengal command in 1879 was 29,129. Of this number, according to ratios per 1,000, there were admitted 2,019·6; there died 32·06; there were invalided 43·60; and there were constantly sick 76·60. The year was comparatively free from cholera. What then, do these figures indicate? Taken by themselves, they may or may not be satisfactory according to the individual views of readers. Let us, therefore, compare them with other statistics having reference to the same command; and having done so, draw such conclusions as may thus be forced upon us. At page 145 of the Blue Book, such a comparison is presented to us ready prepared. Side by side with the figures already given, are others of a similar kind, having reference to the ten years from 1869 to 1878 both inclusive, embracing also two years in which cholera was epidemic, and at least two in which the occurrence of that disease was very similar to what it was in 1879. According to the table therein given, the average annual ratios for 1,000 strength for those ten years were: of admissions 1,466·3; of deaths 21·58; of invalided 42·01; and of constantly sick 57·26. Thus the circumstance transpires that there was in 1879, as compared to a period immediately preceding, an increase in the rate of admissions to 1,000 strength equal to 553·3; of deaths 10·48; of invalided 1·59; and of constantly sick 19·34. If the total inefficiency by deaths and mortality are compared, they give an average for the two years immediately preceding 1879 equal to 63·59 per 1,000 strength, against 75·66 for that year; showing for the latter a very material increase equal to 12·05. It is no easy matter to obtain a fair standard of comparison between statistics as rendered in this Blue Book, and those of years long gone by. Up to a comparatively recent date the numbers of soldiers who were sent home as invalids from India was inconsiderable; hence naturally enough the ratios of mortality appeared much higher than they are with such an efflux of men from the country before organic disease had time to prove fatal to them. And yet, there have been years, when with all those disadvantages, and in what may be called the pre "sanitary" period, when the

death rates compare by no means unfavourably with that of 1879. For example, in 1836 it was 39; in 1855-6 it was 32, precisely as in 1879; in 1859 it was 33; and in 1860 it was 37, so that, in reality, the results of conditions as they now are, contrast by no means so very favourably as might be anticipated with those of the years noted. From 1860 the order of things which so far, has now culminated, has been gradually developing itself. The returns from 1862 inform us as to the variation from year to year, during that interval in the wear and tear by sickness and death among our troops in India. If we contrast the results of the first three years of the period, then begin with the three latest, we learn that the average loss per 1,000 per annum from 1862 to 1864 was 54·86; that of 1877 to 1879 equal to 62·00; in other words, an increase of 7·14 over the first mentioned period. This also contemporaneously with the increase in the financial budget already noticed. Were demonstration required beyond what transpires from daily experience, as to the cost in physical health and human life involved in the conditions attending the service of the British soldier in India, it is to be obtained, clearly and unmistakably expressed in the Army Medical Blue Book for 1879.

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

ABLATION OF FIBROID TUMOURS OF THE UTERUS.—At the Academie de Medecine M. Guéniot communicated some observations on the different methods employed in the ablation of fibroid tumours of the uterus. He would give the preference to excision by the aid of the constrictor or *serre-nerve* on account of its simplicity, and its security. He considered it even superior to Chassaignac's écraseur, in that it can be applied with greater facility, and that it can attain polypi situated on the fundus of the uterus without necessitating a previous traction on the organ. The operation is as bloodless as when the écraseur is employed, and the pedicle is cleanly cut across.

Mr. Teulon read an interesting report on opacity of the vitreous body, and its treatment by electro-therapy upon twenty-four patients observed by him and treated by the continual current, he reckoned twenty-two radically cured. He employs a very few number of elements, and applies the positive pole upon the closed eyelids, and the negative on the mastoid process, or upon the superior servical ganglion. The application lasts only two or three minutes. In conclusion, Mr. Teulon observed that in every opacity of the vitreous body, no matter what may be its degree or extent, provided that its development has not assumed the confirmed form of hypertrophy, that from experience he considered the constant continued currents as the most efficacious treatment.

OSSEOUS LESIONS IN HEMIPLEGIC SUBJECTS.—Before the Société Médicale des Hôpitaux, M. Debove made a few observations on the osseous lesions met with in hemiplegic subjects. As surgeon of the Bicêtre Hospital he had observed several fractures in paralytic subjects, and he soon remarked that the fracture was always on the side of the hemiplegia. There was reason to think that the bones of the affected side had undergone some alteration that rendered them more friable. At the autopsy of an hemiplegic, who had fractured the humerus, M. Debove was able to observe that not only had the fractured bone undergone this alteration, but all the bones of that side were affected. In comparing the two sides he found that the humerus of the side affected with paralysis was lighter than the opposite. On making a transverse section of the bone the medullary canal was larger than usual, and that the substances of the diaphysis was less compact. The Haversian canals were very dilated, and the bone was porous. There was evidence also of fatty degeneration. These lesions were sufficient to explain the relative frequency of fractures in hemiplegics. M. Debove further observed that these fractures united very rapidly.

LINIMENT IN PROLAPSE OF THE UTERUS.—In prolapses of the uterus, M. Cheron, of the St. Lazare Hospital, besides the application of a pessary to keep the organs in position, prescribes the following liniment in order to ease the neuralgic pains from which many patients suffer:—Chloroform three drachms, ether four drachms, camphorated spirits three ounces. These frictions on the lumbo-sacral region are attended with the best effects. Also to restore the tone to the relaxed ligaments he gives:—Bromide of potassium a drachm and a half, tincture of iodine fifteen drops, tincture of aconite twenty-four drops, syrup of tolu ten ounces. A tablespoonful before each repast.

REGISTERED FOR TRANSMISSION ABROAD.

FRESH OBSTRUCTION.

THE determined opposition to scientific progress in this country to which an appearance of authority was most unfortunately and unwisely given by the passing of the Vivisection Act, has, for a period of years, been making steady progress among the emotional and ignorant classes of the community. Few persons, therefore, will be surprised to learn that the society which trades on hysterical sentimentality, and derives its income from the donations of readily impressionable individuals, has at length striven to achieve something more than mere abuse of educated scientists in return for the funds it receives from those who believe in it. It is impossible to regard the silly prosecution of Professor Ferrier, against whom a summons, under the Vivisection Act, was issued by the presiding magistrate at Bow Street on Thursday last, as anything more than a fresh advertisement of the Association, on behalf of whose secretary three barristers made application for a simple summons. It is true that a feeling of dissatisfaction is growing up in some quarters at the manner in which Mr. Adams' society has of late been doing the work for which it professes to receive subscriptions; nor have the laboured efforts of that gentleman himself been quite of a kind to create a very favourable impression either of the

learning or the wisdom with which his attacks on scientific advance have been conducted. The most recent of these is probably known to a good many medical men since it has been widely distributed. It professes to be a reply, "from a scientific point of view," to Professor Owen's late emphatic protest against the vindictive prosecution of experimental physiologists, and written with the aid of a little cheap information, such as may be obtained from superficial study of surgical handbooks; it, no doubt, appealed with some degree of success to the minds of readers utterly without the trained capacity to appreciate the fallacies contained in the work. Following so swiftly on the publication of this misleading pamphlet, the attempt to harass the foremost English experimentalist is a fitting sequel to its production, and will, no doubt, "have" the temporary effect of satisfying the craving for results indulged by every subscriber to the organisation for suppressing the prosecution of physiological science in this country.

From the point of view, however, of an educated intelligence, this last move of the anti-vivisection army is a pitiable indication of the state to which objective study is reduced in our midst. No one probably is more universally recognised as a skilled and trustworthy observer in physiology than Dr. Ferrier, and the many benefits already conferred by him on scientific medicine have earned, as they deserve, the grateful admiration of the whole profession. We may not, possibly, always follow him in his deductions, but as to the value of the observations on which his conclusions are based there can be no two opinions. We need not enter into the abstract question already and often decisively settled in the affirmative to the satisfaction of every capable inquirer, whether or not medicine is indebted to vivisection for any or many of the advances made in its science and practice, but it is as well to consider briefly on what grounds the annoyance to which Professor Ferrier is about to be subjected is justified by its authors.

The act which sanctions such occurrences as will ere long be witnessed, which permits a few frenzied sentimentalists to force a busy man of science through all the worry and expense of time and money incident to a criminal prosecution in courts of law, lays down certain plain directions with which every licenser under its provisions is required to comply. In so far as the prosecutors in the present case have any grounds for their proceeding (outside and beyond the return of a *quid pro quo* to their subscribers) these are contained in the report of certain transactions of the International Medical Congress, contained in a medical paper. This evidence, on the face of it, is inadmissible, and some surprise has not unnaturally been created at the issue of a summons on mere hearsay reports laid before the sitting magistrate. Moreover, even this report contains nothing to show that anything beyond a demonstration of results was exhibited at the Congress meetings; indeed a careful perusal of what took place at Bow Street leaves the impression that there was nothing advanced there to indicate any reason why a summons involving a vast amount of trouble and indignity to a distinguished member of the profession should have been granted. Dr. Ferrier, too, is by no means unaware

of the peculiar conditions surrounding the Society which has selected him as their latest victim. He cannot be ignorant of the vital necessity it is under of doing its utmost to prove worthy of its patrons' shortsighted generosity, and that therefore it is ever on the *qui vive* to discover a *casus belli* against anyone by harassing whom it can hope to distinguish itself. These are not worthy motives of action it must be admitted; but that we are justified in assuming their existence, the lavish expenditure of money in the most silly and useless fashion wherever there is an opportunity of linking the officers of the Association in antagonism with the men of science it must perforce regard as enemies, is surely sufficient proof. Costly advertisements announcing the "beginning of the end," and glorying in the fact that licenses to prosecute original research have been refused to the two greatest living surgeons; reprinting of whole volumes of abusive nonsense against scientific discoverers, uttered by advocates of ignorance, employment of three barristers whose united fees must be a poor man's fortune, to make application for a summons, and which might with equal success have been done for a guinea by a solicitor; all these facts point irresistibly to the conclusion that the present prosecution is likewise a big advertisement, to be followed by an appeal for support on behalf of the Society.

Dr. Ferrier, no less than other witnesses of this Association's peculiar proceedings, is doubtless alive to the readiness with which any departure from prescribed regulations will be forthwith seized on by the lynx-eyed officials of the anti-vivisection brigade, and employed as a means of forwarding the suppression of science. It is difficult, therefore, to imagine that he has been guilty of so serious an omission as is assumed in the application made to Sir J. Ingham on Thursday last. Indeed, we feel certain that there is absolutely no case against Dr. Ferrier, since the course of action he followed at the recent Congress, knowing full well that the vast importance of his communication to the physiology section would at once be the subject of comment in every newspaper in the kingdom, conclusively points to the certainty that he knew himself to be personally protected from the hatred of anti-vivisection agitators. He would not thus have wilfully exposed himself to their machinations had he not this consciousness; and trusting in the security we assume that he enjoys, we sincerely hope the tables may be turned on those who seek thus injuriously to hamper knowledge in this country.

For the purposes sought to be served by the Association for abolishing Science, in bringing this charge it probably matters little who is the object of attack. Prof. Ferrier chanced to *seem* the first experimentalist who laid himself open to prosecution, and the opportunity was seized with a suddenness that may not unlikely be repented. But we ought to remember that the experiments, on account of which this prosecution is instituted, were undertaken with the aid of a grant from the British Association. It will, therefore, be a proper proceeding for that body to charge itself with the defence, taking from Dr. Ferrier as much of the

annoyance as he may be relieved of, and in its own person defending the dignity of research against ignorant or interested calumniators. The battle to be fought out is, we must not forget, an important trial of strength, with facts of recent origin all pointing to the determined nature of the opposition being constantly offered to progress in experimental physiology. The best interests of medicine, and the highest interests of humanity, moreover, are involved in the struggle which must sooner or later ensue, and which it may be almost on us now. It will have to be decided whether these interests are to give way to mere hysterical sentiment, or whether the universal agreement of men of science and of standing in the medical world, is to be accepted as of less weight on a purely medical question than the ravings of a band of hyper-sensitive and over-affectionate persons, of whatever social condition they may be.

Be the issue of the hearing appointed at Bow Street Police Court for November 17th what it may—and we feel secure in the acquittal of Dr. Ferrier—it must remain a lasting reproach to the English nation that it will permit an earnest and eminent physician to be called to defend his ardour in pursuit of the knowledge whereby mankind is benefited; and this at the instigation of those utterly incapable of judging either his motives or the consequences flowing from them.

THE TENURE OF OFFICE OF IRISH POOR-LAW MEDICAL OFFICERS.

THE summary dismissal of Dr. Kenny from the office of medical officer to the North Dublin Workhouse, because of his being confined as a "suspect" under the Coercion Act, has evoked, as we anticipated, a storm of indignation, partly genuine and partly sham. Apart from the matter-of-course horror of a certain class of politicians, an almost universal feeling of displeasure has been manifested by those who care little for politics, but who feel strongly about the arbitrary course adopted by the Local Government Board, and who strenuously object to the establishment of a precedent for the dismissal of Poor-law medical officers on other grounds than their fitness for duty. As we pointed out last week the power of the Board to dismiss an officer, is derived from the 33rd Section of the Poor Relief Act of 1838 (1 and 2 Vict., cap. 56), which authorises them to "remove any paid officer whom they shall deem unfit for, or competent to, discharge the duties of his office."

As to the interpretation of the word "unfit," we expressed the opinion that the word is restricted in its operation to some disqualification for the performance of medical duties, and that the Local Government Board had not any right to use the phrase to cover all sorts of matters of which they happen to disapprove. If Dr. Kenny were habitually intemperate, or if he were guilty of any immoral conduct in his capacity of medical officer, he would be obviously "unfit" for office. But, if we are correctly advised, the Board has no right of dismissal unless there exists some disqualification which prevents the medical officer from the due performance of his functions.

It would indeed be as reasonable that a board of enthusiastic Protestants should dismiss an officer because he turned Catholic, or because he married his deceased wife's sister, as that they should cast him out because he holds extreme political opinions. We hold, in fact, that the Board is legally responsible to interpret in a reasonable sense the words of the Act, and that any unreasonable interpretation of them might be reversed in the court of appeal.

Whether we are right or wrong in this interpretation of the law remains to be proved, and Dr. Kenny states that he has taken the necessary steps to test the validity of the sealed order of the Board, and to obtain a decision from the highest authority as to whether a workhouse officer is liable to removal without accusation, investigation, or the opportunity for explanation, and for an offence entirely outside his medical functions.

We observe that at the last meeting of the North Dublin Guardians, the local government inspector challenged our statement "that no officer dismissed by sealed order could ever again hold a Poor-law appointment." He asserted that all dispensary appointments, being held under the Medical Charities Acts, were open to medical officers dismissed from workhouses under the Poor Relief Acts, and that they might even be re-appointed to workhouse offices, if the Local Government Board gave their sanction.

As to the parallel thus drawn between workhouse and dispensary appointments, we quote the words of the Act:—"Any person so removed shall not be competent to be appointed to, or to fill any paid office connected with the relief or management of the destitute poor in any Union, except with the consent of the Commissioners." We are glad to have official authority for the view that this phrase does not include medical charities appointments, though it certainly seems sufficiently comprehensive to do so.

As to the suggestion that Dr. Kenny is, after all, not so much aggrieved because he might, "with the consent of the Commissioners," return to the Poor-law Service, we would be pleased if any one could adduce a single case, since this service was established, in which "the consent of the Commissioners" has been given to the re-appointment of a dismissed medical officer. We know of more than one case in which such officers have been prevented seeking re-appointment by the intimation that their election would not be sanctioned, and we are quite clear that Dr. Kenny is as completely driven out of the workhouse medical service as if his dismissal were absolutely irrevocable.

Nothing that has been said on behalf of the Local Government Board since the issue of their sealed order, has in the least shaken our opinion that the dismissal of Dr. Kenny—though it may have been barely legal—was hasty, arbitrary, and precedent of evil purport for all Poor-law medical officers, and that the occasion requires that the summary exercise of such a power as that which the Board has assumed, should be emphatically and universally repudiated by those who speak on behalf of the medical profession in Ireland.

"CHOLERAIC FEVER."

ACCORDING to recent accounts from India "choleraic fever" was raging in Umritsur. Business in that city was at a stand-still, and nine-tenths of the shops were closed. The appearance of the place was described as that of a city of the dead. Not a single European has escaped attack; the railway, post, and telegraph offices were working under great difficulties owing to sickness among their employes.

The circumstance of these two forms of disease prevailing together induces us to refer to the history of similar recurrences. Accordingly, it appears that the Hindoo physicians recognised the combined affection under the name of *Jwar antishar*, that is, fever with the excessive purging. They recognised the fact that soils favourable to the occurrence of fever were so also to that of cholera; further, that in such localities fever usually prevailed in the hot season, cholera in autumn; that on occasions the two affections prevail together; in others that they succeed each other. They were aware of the circumstance that in some cases of what appeared to be pure fever, the patients succumbed to choleraic symptoms. Now, recent experience illustrates the frequency with which what is known as secondary fever succeeds primary attacks of cholera; yet, notwithstanding the intimate relation which exists between both affections, it is a point to be noted that, whereas cholera epidemics often take their rise from assemblages of pilgrims, those of fever do not.

In the sixteenth century a connection was believed to exist between cholera and the double tertian fevers of Egypt. In the summer of 1610 there prevailed in England tertian ague, yellow fever, and choleraic fluxes. In 1756 to 1773 the severe form of fever which at that time attacked the crews of ships in the Hooghly, at Diamond Harbour, was attended by symptoms of cholera. In 1765 a choleraic form of fever is stated to have prevailed at Montpellier. In 1788, in England, cholera was considered "symptomatic" in ague and remittent fevers. Coming down to times more recent, in 1833 cholera and fever prevailed together in the districts around Hosunabad to such a degree that they were looked upon as endemic in that part of India. In Europe the prevalence of several other zymotic diseases has been observed during outbreaks of cholera. In 1832, and again in 1848, the advent of cholera in England was preceded by "fluxes;" while the epidemic raged there was an increase in typhus as compared with other years, and influenza of a fatal form was also present. In 1834 Calcutta was visited by what at the time was called "cholera fever." It first appeared in May, the worst of the cholera months; it continued throughout June, and disappeared with the full setting in of the rainy season. On that occasion attacks of fever were prone to merge into pure cholera. In 1861, at Lahore, Umritsur, Agra, and some other places cholera was accompanied, or followed, by an excessive prevalence of intermittent fever. The season in which the cholera outbreak took place was, however, that in which malarial diseases usually prevail. In 1865, prior to the recurrence of cholera in St. Petersburg, cerebro-spinal and relapsing fever occurred. In 1875-6, while cholera was prevailing in Central India, the troops and general population suffered from fever. In the latter

year the troops were severely affected with heat-apoplexy. In 1876 the districts of the Panjab, which suffered most severely from fever, escaped cholera. On the other hand, the fever mortality was comparatively low in the districts that suffered most severely from cholera.

DESPAIR.

It may seem somewhat beyond the province of a medical journal to notice the last contribution of the Laureate to poetical literature, but as Mr. Tennyson has gone somewhat out of his way to create prejudice against the practitioners of medicine and to disparage their methods of research, he cannot complain if a medical critic quits the beaten track of inductive science to glance for a moment at one of those imaginative flights by which he is supposed to delight, console, or inspire the English-speaking races of mankind. And even apart from any principle of reciprocity, it is justifiable and expedient that Mr. Tennyson's most recent flight should receive some medical attention, for if we might so say, it is pathological in its character, and reminds us rather of the convulsive plunging of a broken pinion than of the free and majestic sweep of a strong and healthy wing. "Despair," with which the *Nineteenth Century* opens this month, and which is proudly pranked in large type and heavy leading, is really a study of suicide, and as such will perhaps be best appreciated by those who have to deal practically with the mental infirmities of which suicide is generally the expression, and receive the confessions of those who have unsuccessfully attempted it; and their judgment will not, we conceive, be favourable to the motive, veracity, or influence of Mr. Tennyson's "Bridge of Sighs," or rather "Bridge of Groans." Leaving to others the discussion of its literary merits, or paying a passing tribute of admiration to those felicities of expression which adorn it, as indeed they do every poem of the Laureate, they will ask themselves what good purpose this work is likely to serve, and whether it is true to life and nature, to life in its direst extremity of suffering, and to nature in the strange clash and conflict of her forces. And in seeking an answer to these questions they will not have to pause to consider the sources of tragic emotion, nor the pleasures that are begotten by the contemplation of grief and calamity; for this poem, although called dramatic, is not a tragedy, but mere wailing and gnashing of teeth. There is in it nothing ennobling or sacrificial, no heroic action of illustrious men, no stately fatalism, no ray of brightness shining through the gloom. It is blank despondency and hideous egotism, and no one can rise from the perusal of it with any new insight into the mystery of being, with any sense of exaltation or refinement, or with any benevolent impulse or wise resolve. The feelings which it evokes are really those which might be called forth by a blending of the police news with the most offensive effusions of atheism, and it is difficult to understand what aim the Laureate has held in view in placing before the public so deleterious a compound. To clothe in choice language and to connect with modern speculation the doubts and fears that have vexed humanity in its moments of weakness, ever since it began to look before and after, is not to justify

the presentation of so dark a picture; and to paint in repulsive colours the end of the agnostic in order to make his infidelity distasteful would be like exhibiting the sores in an hospital as a deterrent from vice.

Despair is a monologue, but not like the grandest and subtlest dramatic poem on suicide, a soliloquy, for it is addressed by a man who has been rescued from suicide, to the minister of some Calvinistic sect who had saved him from self-destruction, and who is now endeavouring to save him from the spiritual destitution that had driven him to attempt to put an end to his existence. Composed chiefly of the repinings and blasphemies of the would-be suicide, interspersed with a few biographical details and fine descriptive touches, it includes some of the minister's comments and arguments, which are reproduced in the discourse of the prostrate man, to whom they are addressed. And with reference to these comments and arguments we must observe that the minister either must be very unjustly represented by the fragments of his speech which are repeated, or must have been but a poor specimen of his class, with little to say for the faith that is in him. There are but few clergymen of any sect who could not have met the ravings of the suicide with suggestions more acute and penetrating than those which are quoted in the monologue with bitter derision and contempt. But whatever the dialectical skill and theological knowledge of the minister may have been, he was certainly entitled to more courtesy than he receives from the man with whom he converses. We are told that he had been the minister of this man and his wife when they were still attached to the Christian faith, and that even after they had abandoned his fold he continued to watch over them during their gradual decadence into unbelief and hopelessness. And when at last the unhappy couple in supreme misery resolved to end themselves by drowning, this minister followed them as they went forth to effect their purpose, and drew the man from the water, although he could not succeed in rescuing the woman. Surely, then, he was entitled, if not to gratitude for services rendered, at least to respectful recognition of his good intentions, and there are very few even determined suicides, retaining their reasoning faculties, who at a short interval after the rash act, would not in some degree appreciate the goodness that had frustrated their attempt. Not so, however, Mr. Tennyson's graceless subject, who can only abuse the man who had "dogged" him and dragged him to land, and outrage his most cherished sentiments by gratuitous impieties.

The man and would-be suicide whose mental condition Mr. Tennyson sets himself to reveal is an agnostic of a common type, who, by a too exclusive attention to material facts, has lost hold, one by one, of spiritual beliefs. By persevering efforts he has circumscribed his powers, and lost sight of the sun while basking in the splendour of the electric light. At first the process of self-mutilation was delightful. He seemed to throw off rudimentary appendages, to strip himself of useless encumbrances, and to rise as he did so, by the levitation of self-esteem, above the heads of his fellow men, who remained sunk in superstition, and bound by cramping creeds. It was only after he had attained to a great

height of intellectual enlightenment that new miseries, worse than those he had abandoned, assailed him, and that his enfeebled and crippled nature succumbed to the disasters of life. And yet, even at the last, when ready to end his wretched life, he is not a downright agnostic; and herein he does credit to Mr. Tennyson's judgment and observation, for a downright and thorough agnostic, if such there be, who has involuted himself to the point of getting rid of religiosity altogether, is not likely to commit suicide. In that respect he would be on a level with the brutes that perish, and would enjoy his animal existence to the dregs, come what may. It is the incomplete agnostic, with broken faith, with strong phrases on his tongue, but with occasional dim glimmerings in his heart that there may be a God behind all; with an inability to grasp either a hope of futurity or an assurance of annihilation; with the righteous feelings that grew out of his religious sense still vigorous within him, although the parent sense is no more—he it is that finds the burden of life insupportable. And this incomplete agnosticism it is that has been causing an increase in the number of suicides in most European countries of late years. Frequent in Pagan ages, suicide declined under the influence of Christianity, and reached a minimum when faith was most in the ascendant. Since the decay of faith set in it has advanced once more, and a rapid revival of suicide is now going on. The rate of suicide calculated on the entire population of Europe, without distinction of nationality, or of local variations, has been more than quintupled since the middle of the last century; and who can guess when suicide may reach its maximum amongst us!

But the suicides that are due to incomplete agnosticism, are not due to it alone. Agnosticism is, as it were, the predisposing cause, but some more pressing and personal grief or misfortune is required to precipitate the catastrophe. An agnostic, more or less pronounced, may march through life pretty comfortably, if things go smoothly with him, and if he has a fair share of wealth, honour and enjoyment. It is only when trials, losses and disgraces fall upon him, that he finds it no longer worth while to go on living, and in some peculiarly excruciating moment, shuffles off this mortal coil, or tries to do so. And this, too, Mr. Tennyson has justly observed, for his agnostic does not think of drowning himself until ruined by the forgery of one son, bereaved by the death of another, and distracted by the knowledge that his wife is labouring under cancer, which can only be cured, if cured, by the surgeon's knife. It is when thus disgraced and anguished, without hope in this world or the next, that the fear, nay, the foreshadowing of madness, comes to reinforce his misery, and convert it to despair, and so his wife and he agree to drown themselves together, thus entering into a criminal compact, possible to youthful and romantic lovers, thwarted in passion, almost unknown in aged persons.

But while correct, thus far in indicating the predisposing and exciting causes of the attempted suicide in the case with which he is dealing, Mr. Tennyson fails in many other points in mental analysis in the poem. For instance, he tries to show that pity was a factor in the

despair of the man and woman, and so conducive to their suicide.

Pity for all that aches in the grasp of an idiot power,
And pity for our own selves on an earth that bore not a
flower ;

Pity for all that suffers on land or in air or the deep,
And pity for our own selves till we longed for eternal sleep.

Pity for their own selves doubtless played an important part in leading this forlorn pair to throw themselves into the sea, but pity for all that suffers had certainly nothing to do with the transaction, for compassion for the miseries of others serves as an effectual check on resentment and selfishness, by prompting us to prevent misery by checking the violence of our own evil passions, and to relieve misery by engaging in good offices for the benefit of every object of compassion within our reach. It is directly opposed to those narrow, egotistic, querulous feelings that lead to suicide. No truly pitiful man will destroy himself.

Despair ends with a grim note of defiance. The victim of despair predicts that he will escape in spite of the lynx eyes of those who watch over him, and that an orthodox coroner will consign him to a stake and the cross-road by a verdict of *felo-de-se*. Thus the painful—might it not be said revolting?—impression created by the poem is sustained to the last, and we turn from it with the conviction that it would have been better unwritten. Such morbid studies will not add to the reputation of the Laureate nor give pleasure or encouragement in any human being.

Notes on Current Topics.

The President of the Royal College of Surgeons.

WE are quite sure that in offering sincere and hearty congratulations to the President of the College of Surgeons on the distinguished honour of knighthood which Her Majesty has been pleased to bestow upon him, we shall only be giving expression to a widespread feeling of pleasure which must prevail throughout the profession of medicine. The graceful recognition of the many munificent and benevolent acts which Sir Erasmus Wilson, in the largeness of his heart has been prompted to exercise for the sole qualification of doing good, and seeing his good works fructify during his lifetime, is an example that few amongst us can hope in any way to imitate or emulate. We may well feel proud of one who, not only knows how and when to do a benevolent act, but who feels equal pleasure in dividing his substance for the encouragement of his profession, and the development of medical study—a work which in its aim and usefulness to mankind is of more value than any number of Cleopatra's Needles. The honour could not well have come more gracefully than it has through Mr. Gladstone, or at a more appropriate time, when, as the representative head of English surgery, it reflects equal honour upon the body of the profession as upon one we all delight to honour as the President of the Royal College of Surgeons of England.

More Fever Dens.

THE West end of London is not, it would seem, to monopolise the questionable privilege of having in its midst ill-ventilated, ill-drained dwellings to serve the purpose of breeding grounds for fever. Sir John Humphreys elicited facts at an inquiry held before him on Thursday last concerning the death of a child two years old, which unquestionably suggest the probability of there being houses in the East as detrimental to human life as those just condemned in Lisson Grove, Marylebone. According to the evidence referred to, a house in Usher Road, Bow, is underlaid by a filthy, rotting mass of material in somewhat the same fashion as the Lisson Grove houses. An examination of the premises, made by Mr. Hamblin, a surgeon, led to the discovery of a most inefficient system of drainage, and to the fact that highly offensive odours were given forth from beneath the basement flooring, which in great measure contributed not only to the death of the deceased child, but also to that of three other members of the same family living in the house. So impressed was the coroner with the description given to him that he adjourned the inquest in order that in the meantime a full investigation of the state of the dwellings should be made, and their condition reported on. It is satisfactory to find this willingness to insist on hygienic measures, although it is no more than might have been safely anticipated from Sir John Humphreys. We shall await with interest the result of the sanitary inspector's investigation.

The late Drs. Hayden and McClintock.

AMONG the many honourable offices held by these eminent physicians, one of not the least importance, as showing the estimation in which they were held by their professional brethren, was the post of President and President-elect respectively of the Dublin Branch of the British Medical Association which they occupied at the time of their deaths. The loss the Dublin Branch sustained by the deaths of its two principal officers is indeed a serious one. Its members, however, will be gratified at the sympathy which is felt with them by other branches of the Association. At a largely attended meeting of the Council of the Metropolitan Counties (London) Branch held on Friday, the following resolution was unanimously adopted:—"That this Council, having heard with much regret of the recent death of Dr. Thomas Hayden, the President of the Dublin Branch of the British Medical Association, and Dr. Alfred McClintock, the President-elect of the same Branch, desires to express to the Council and members of the Dublin Branch its fraternal sympathy with them in the loss which they have sustained by the removal of two such eminent and highly-esteemed members of the Association."

THE report of the Dwellings Committee of the Charity Organisation Society shows that about three millions sterling are now in the hands of 876 building societies in all parts of England. The influence of railway facilities in inducing artisans to obtain dwellings in the suburbs has been such, that workmen earning only ordinary wages have become, through these societies, possessors of the houses they occupied.

Durham University School of Medicine.

THE entries at Durham University School of Medicine, Newcastle-on-Tyne, as previously published, are, we are informed, incorrect. The amended returns give a total of seventy-four new students; of this number thirty-five have joined for the full course of instruction, while thirty-nine are candidates for the M.B. degree of the University, such candidates being required by statute to spend one year of residence within the academical limits. These numbers, however, sufficiently testify to the growing popularity of the Durham School, and point to a well-deserved success attending the liberal regulations for obtaining a degree in medicine in vogue at Durham for the last few years.

American Opinion on the late President's Case.

WE have purposely avoided reference to the case of the late President Garfield since the publication of the report drawn up by the surgeons who made the post-mortem examination of the body, feeling that it would be better to leave unsaid what we could not avoid saying had we considered the report at all. The *Detroit Lancet*, however, for October, writes in somewhat emphatic terms concerning the official bulletin. It remarks, "The document furnishes a basis for the comprehension of the symptoms exhibited by the President during his late illness. It will at once appear how far from the mark all opinions and experiments were. The boast of surgery to an exact science are sadly out of place in this case. Nor is it at all satisfactory to think what might have been. We shall no doubt have full and explicit histories of the case. But we fear it will be impossible to remove the impression from the popular mind that the head surgeon in the case acted the part of either an incompetent or of a dishonest man. In either case the profession has fallen in the minds of the people lower than it was. . . . One lesson we learn is, that many doctors in the case is clearly an evil. To be overhauled daily, or many times each day, by half-a-dozen doctors, more or less, is enough to kill even a strong man. . . . Many persons and many journals will doubtless indulge in a big job of whitewashing. But it will not at all repair the damage done to the good name of the medical profession. Still, doubtless, the best thing that can be done is to go about some better work than recounting the regretted past. No use 'to cry over spoiled milk.'"

An Unpleasant Patient.

IT is narrated in a recent number of the *Lyon Medicale*, that a *restaurateur* had been sent to Bicêtre asylum, and having been treated during eleven months, was dismissed in an apparently satisfactory state. Next day, having been drinking, he again showed signs of insanity, and his wife sent for the doctor, who ordered him a strict diet and abstinence from drink. On hearing this, the madman rushing upon the doctor, drew him to the window, which he threw open, and seizing him by the neck, held him suspended in the open air. More dead than alive, the doctor dared make no struggle, while his dangerous patient howled like one possessed, and threatened to let him drop. The neighbours, finding how things stood,

obtained a ladder, and one of them mounting it, got hold of the unfortunate doctor. He was, however, not yet saved, for the lunatic refused to relax his hold, and, in fact, did not abandon his prey until a blacksmith burned his hands with a red hot iron. The madman was taken back to Bicêtre.

Fever in Private Houses.

THE serious dangers to the public attendant on the occurrence of fever cases in the private dwellings of the poor were forcibly exhibited at an inquest held by Dr. Danford Thomas on Thursday last, on the body of a girl, aged twelve years, who died from scarlet fever. It transpired that deceased and two other children slept in the same room with their parents in a house in Somers Town. The sisters of the dead child had also had scarlet fever, and one got well over it. The medical attendant gave evidence to the effect that he had been called to see the deceased, having previously attended her sisters for scarlet fever, but death occurred before his arrival. He said he had advised the removal of the other children to a fever hospital, but that the parents strongly objected to such a proceeding. The unwillingness of the poorer classes to adopt this plan in case of fever in their families was commented on by the coroner, who added that if it was more generally understood how well these institutions were conducted, there could be no opposition to their being used on behalf of fever patients. In addition, the safety of the public demanded that where isolation of each case as it arises was impossible, removal to a special hospital should be forthwith adopted. The necessity for a fixed rule of this kind was shown by the fact that the lower rooms of the house in which these cases occurred were used as a public laundry; and the capabilities of far-spreading infection thus presented were likely to create an uneasy feeling among the vast numbers of families whose habit it is to "put out" their washing. The question is a serious one, worthy of serious consideration.

Anti-Vaccination Law.

ON the hearing of several summonses by the Brighton magistrates, last week, against persons charged with disobeying orders already made upon them to have their children vaccinated, one of the defendants urged a new objection, and called upon the magistrates to refuse the administration of the oath to the vaccination officer on the ground that he was an atheist. This the latter denied, and said he had not any objection to the oath; upon which the defendant rejoined, that those who ignored the perfection of the Almighty's handiwork, as did the supporters of vaccination were just as atheistic as those who repudiated the existence of a Supreme Being. The Bench was not at all impressed with the validity of this new line of objection, and fined each defendant 10s. and costs.

THE Hospital Saturday and Sunday Collections in Liverpool this year produced £10,027, an increase of £306 over last year. At the meeting of the committee last week, the Mayor announced that, by the death of Miss Hamilton, £16,000 had fallen into the hands of the Corporation, for distribution amongst the charities of Liverpool.

St. Matthew, Bethnal Green.

THE Annual Report for 1880-81 of the Medical Officer of Health for the parish of Bethnal Green (Dr. G. Paddock) has just been issued. The number of deaths in the period was 2,883, or 89 less than the preceding twelve months. These, however, include 126 non-parishioners, temporarily placed in medical institutions in the parish. This gives an annual rate of 23·2 per thousand. There were 5,201 births; and of the deaths, 29·2 per cent. were of infants, under one year, *atrophy and debility* being the cause most numerously assigned. Zymotics caused 615 deaths, 498 being children under five; small-pox, 20; and whooping-cough, 140. There were 405 cases of small-pox reported in the year: 20 died at home, and 31 in hospitals. Dr. Paddock adds elaborate and valuable statistical tables, and lengthy reports on various subjects.

The Health of Ireland, for the Quarter ending Saturday, October 1st.

IN the Dublin district there was registered during the thirteen weeks a birth-rate of 29·1 in every 1,000 of the population. There was registered in London during the same period a birth-rate of 33·4 in every 1,000; in Glasgow, 35·9; and in Edinburgh, 31·1.

The deaths in the Dublin district during the quarter amounted to 1,743, affording an annual ratio of 20·0 in every 1,000. The average in the third quarter of the ten years, 1871-80, was 22·1 per 1,000 persons. As was pointed out in previous reports, the burial returns under the Public Health Act came into force in 1879, raising the number of deaths registered by about 10 per cent. over the number registered in previous years. In addition to these returns further improvements in registration have been produced by the action of the "Births and Deaths Registration Act (Ireland), 1880," which came into force on the 1st of January of this year. On the other hand, the extension of the area of the Dublin registration district has included some suburban districts, the rate of mortality in which being comparatively low, tends to cause an apparent decrease in the general death-rate of the district beyond that which has really taken place.

The deaths registered compared with those registered in the corresponding quarter of the year 1880 shows a substantial decrease in all except two of the sixteen town districts. A comparison for the same period gives the following percentages of decreased mortality:—Dundalk, 58·8; Newry, 53·5; Waterford, 52·5; Sligo, 49·4; Queenstown, 48·8; Drogheda, 43·8; Wexford, 43·5; Lurgan, 40·0; Galway, 37·7; Dublin registration district, 36·6; Cork, 21·2; Londonderry, 19·7; Belfast, 17·5; and Limerick, 16·7; the total decrease during the quarter in the sixteen town districts being equal to 31 per cent.

The quarterly return for Ireland, now in course of tabulation, points to a general low rate of mortality throughout the country; and it is more than probable that the rate has not been so low in the third quarter of any year since registration commenced. This exceptionally healthy state of the population in the autumn quarter must be chiefly ascribed to a cool summer, which is (as is well known) nearly always accompanied by a low mortality. No

doubt abundant and cheap provisions have also much to do with diminished prevalence of disease among the labouring class.

In the Dublin district the deaths have been lower than in the third quarter of any year since 1871. In the City of Dublin the death-rate in the third quarter has not been so low since 1876. Compared with the corresponding quarter of the year 1880, the number of registered deaths is 41·0 per cent. less in the city, and 29·1 per cent. less in the suburbs of Dublin.

In London there was a mortality of 20·4 in every 1,000; in Glasgow, 20·7; and in Edinburgh, 16·9.

The deaths from zymotic diseases registered were 232, being 3 under the number for the preceding quarter, and 245, or 49 per cent., below the average for the third quarter of the last ten years. The deaths from these diseases are equal to an annual rate of 2·7 per 1,000 of the population. There were no deaths from small-pox registered.

Overcrowding in London.

PUBLIC attention having been directed to the alleged overcrowding of houses in Windsor Street, and other streets in Bishopsgate, a night inspection had been made, and, while the result did not justify the charge of overcrowding, it was impossible to exaggerate the dirty condition of the premises, owing to the filthy habits of the inmates. In Windsor Street there were 12 houses with 103 rooms, in which 359 people dwelt; in Widgate Street, 7 houses, 48 rooms, and 88 persons; in Sandy Row, 6 houses, 49 rooms, and 124 persons; and in Catherine Wheel Alley, 3 houses, 16 rooms, and 73 persons.

Clairvoyant Diagnosis.

THE following clear and highly scientific diagnosis was obtained from a clairvoyant, and sent to the *New York Medical Record* for publication:—"This lady has a slight congestion of womb and ligaments, attended with neuralgia, which, from a reflex action and sympathetic condition, affects the brain. The liver has malarial symptoms, affecting the stomach and system generally or constitutionally, and causing an impoverishment of the blood and nervous irritation. The condition of the system at present requires local healing and astringent treatment for the uterus, and tonic anti-malarial remedies for the general depletion of the system.

A New Dwarf.

AT the last monthly meeting of the "Pressé Scientifique," in Paris, a dwarf, a boy about 14, was exhibited. He is about 80 centimètres, or about 30 inches, in height, and weighs only 9 kilogrammes, or about 18 pounds. His head is small, but not out of proportion with the rest of his body. He was subsequently exhibited at the Academy of Medicine, where M. Jules Guérin pronounced the head to be an example of "microcéphalie généralisée." His intelligence is about the average of boys of his age and station in life, and he has the air of importance peculiar to dwarfs. His parents, who are French peasants, are of ordinary stature, and so is his elder brother. He is well made, has rather an aquiline nose, and reminds one of the model ☺

wax of the dwarf "Bébé," twenty inches high, to be seen under a glass bell in the anatomical museum attached to the School of Medicine.

Medical Society of the College of Physicians of Ireland.

THE annual general meeting of the Society, for the election of office-bearers, was held in the large hall of the King and Queen's College of Physicians in Ireland, Kildare Street, Dublin, on Wednesday, October 26th. The chair was taken by Dr. J. W. Moore, Vice-President of the College. The following members of the Society were elected as officers for the session 1881-82, viz. :—
President: George Johnston, M.D., President of the College of Physicians. *Vice-Presidents*: John William Moore, M.D., Vice-President of the College of Physicians; Thomas Fitzpatrick, M.D. *Council*: J. Hawtrey Benson, M.D.; Fleetwood Churchill, F.K. & Q.C.P.; John Magee Finny, M.D.; Arthur Wynne Foot, M.D.; Samuel Gordon, M.D.; Thomas Wrigley Grimshaw, M.D.; Reuben Joshua Harvey, M.D.; Thomas Hayden, F.K. & Q.C.P.; Surgeon-Major Jackson, C.B.; Henry Kennedy, M.B.; Christopher J. Nixon, M.D.; Walter George Smith, M.D. *Honorary Secretary and Treasurer*: Alexander Nixon Montgomery, M.K. & Q.C.P.

Treatment of Goitre by Iodoform.

M. BOECHAT (*Correspondenz Blatt f. Schweizer Aerzte*) has employed iodoform in the treatment of goitre, (1) by external application the author has employed a glycerole covered with a layer of collodion, the results were nil in old cystic or parenchymatous goitres. In recent goitres on the other hand of soft consistence the tumour diminished more rapidly than with iodine or iodide of potassium; the odour is a serious inconvenience. 2. Internally, Boechat prescribes iodoform in pills of one centigramme, not more than ten a day. This treatment has only been applied in the case of two patients with old standing goitres. 3. M. Boechat has employed interstitial injection in three cases. The first patient who had a goitre from infancy, received, for fifteen days, the injection of half of a Pravaz syringe of a saturated solution of iodoform in ether. Cessation was necessary on account of very intense inflammatory reaction, but the goitre was markedly diminished. In the second case two injections were sufficient to cause amelioration in an old standing goitre. In the third case, a very old goitre, suppuration took place with no improvement. To sum up, M. Boechat believes that this is a useful method which might become more general.

THE London Statistical Society will hold its monthly meetings, during the session of 1881-2, on the third Tuesday in the months of November to June, when the following papers, among others, will be communicated to the Society: "The Relative Mortality of Large and Small Hospitals, their Advantages and Disadvantages considered," by Henry C. Burdett, Esq.; "Two Hundred and Fifty Years of Small-pox in England," by William A. Guy, M.D., F.R.C.P., F.R.S. The general anniversary meeting will be held on June 27th, 1882, at p.m.

The Use of Fumigations of Tincture of Iodine.

THE powerful resolutive action of iodine, says M. Gueneau de Mussy, indicates its use in a large number of congestive and inflammatory affections of a subacute or chronic form (*Le Praticien*). There are cases, however, where its direct application to the diseased organ meets with some difficulties; in affections of the tympanic cavity, for example, the membrane tolerates badly applications of tincture of iodine. The author recommends the following proceeding which, without inflaming the tissues brings them in contact with the remedy; a small ball of iodised cotton is enveloped in cotton wool and introduced into the ear; the iodine is exhaled in the meatus and forms an iodised atmosphere over the membrane, at the end of twenty-four or thirty-six hours the cotton is decolourised, and should be removed.

M. de Mussy has applied the same proceeding with marked advantage in a case of chronic engorgement of the uterus. Besides general treatment and the use of belladonna suppositories, he prescribed tepid injections every evening of infusion of camomile and borax; immediately after these injections he introduced into the vagina a tampon of iodised cotton covered with cotton wool. Besides this direct resolutive action the author attributes to iodine emmenagogue properties, and warns against the use of applications of iodised cotton in women subject to metrorrhagia.

The Adelaide Hospital, Dublin.

It is generally understood that Dr. Wallace Beatty will probably succeed to the vacancy in the Assistant-Physiciancy of this hospital caused by the election of Dr. Walter Smith to the King's Professorship of Materia Medica in the Trinity College School of Physic, which appointment involves the transference of Dr. Smith to the Physiciancy of Sir Patrick Dun's Hospital.

THE *Citizen* states that the governors have determined to ask the Duke of Edinburgh to allow himself to be put in nomination for election as President of St. Thomas's Hospital.

DR. MANGET, Surgeon-General of Demerara, writes that the type of the present epidemic of yellow fever is not similar to previous ones; and that the old treatment of calomel and quinine has not, in consequence, proved so successful as heretofore.

THE Earl of Leicester, Holkham Park, Norfolk, has given the munificent sum of £15,000 to the Norfolk and Norwich Hospital, of which he is President, to be added to the endowment fund. The late Mr. Sewell, of Reepham, Norfolk, has bequeathed to the same hospital, £1,000.

AT the Middlesex October sessions last week, the following salaries were authorised to be paid to the several coroners of the county as from the 31st of December last, viz., Sir John Humphreys, £2,207; Dr. D. Thomas, £2,099; Dr. Diplock, £800; Mr. W. J. Payne, £54; and Mr. E. St. Clair Bedford, £500.

ONE of the oldest fellows of the Royal College of Surgeons of England has just past away in the person of Thomas Michael Greenhow, M.D. Durh., F.R.C.S. Eng., consulting surgeon to the Newcastle-on-Tyne Infirmary. The deceased was in the ninetieth year of his age, his diploma of membership bearing date August 5th, 1814.

THE mortality is still very high from zymotic diseases in some of the principal foreign cities. Paris last week gave a death-rate of 47 from typhoid and 52 from croup; Berlin 28 from diphtheria and 25 from scarlet fever; New York 50 from diphtheria and 24 from scarlet fever. In the latter city the entire death-rate is higher than all the other large cities of the world—Alexandria and St. Petersburg alone excepted.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population, were—Plymouth 13, Sheffield 16, Edinburgh 18, Birmingham 19, Leeds 19, Portsmouth 20, Bristol 20, Salford 20, Bradford 21, Sunderland 21, London 21, Nottingham 21, Brighton 21, Leicester 22, Dublin 23, Oldham 23, Manchester 23, Glasgow 24, Norwich 24, Newcastle-on-Tyne 25, Wolverhampton 25, Liverpool 27, and Hull 33.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Bombay 27, Paris 27, Geneva 20, Brussels (with 8 Faubourgs) 19, Amsterdam 24, Rotterdam 23, The Hague 17, Copenhagen 15, Stockholm 22, Christiania 13, St. Petersburg 42, Berlin 24, Hamburg 21, Dresden 19, Breslau 26, Munich 28, Vienna 22, Prague 24, Buda-Pesth 31, Rome 22, Naples 28, Turin 17, Alexandria 45, New York 33, Brooklyn 26, Philadelphia 20, and Baltimore 25. No returns were received from Calcutta, Madras, Venice, or Lisbon.

FROM diseases of the zymotic class in the large towns last week scarlet fever showed the largest proportional fatality in Hull, Sunderland, Brighton, and Nottingham; in Hull 39 more fatal cases of this disease were recorded, making 357 that have occurred since the beginning of July. The 47 deaths from diphtheria included 25 in London, 11 in Glasgow, and 7 in Portsmouth. The highest death-rate from fever (enteric) occurred in Brighton, Bristol, and Leeds. An outbreak of measles was recorded in Leeds. Small-pox caused 25 more deaths in London and its outer ring of suburban districts; one each in Salford and Newcastle-upon-Tyne, but none elsewhere.

University of Cambridge.—Dr. Watney and Dr. Creighton have been appointed Examiners for the Second M.B. Examination; Dr. Reginald Thompson and Dr. Galabin Examiners for the third M.B.; and Mr. Luther Holden and Mr. Thomas Bryant, Examiners for Medical and Surgical Degrees during the ensuing year. Dr. Cheadle has been appointed Assessor to the Regius Professor of Physics. The degree of M.B. has been conferred on Edward Ground, Downing College.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE ROYAL MEDICAL SOCIETY OF EDINBURGH.—The current session of the Royal Medical Society of Edinburgh was inaugurated on the 4th inst., by Professor Dickson, who delivered an address to a large audience of medical practitioners and students, in the Hall of the Society, George IV Bridge. Dr. Dobie, senior president of the society, occupied the chair, and among those present were Dr. Rutherford and Mr. Chiene. Dr. Dickson urged upon the students the value of such a society, where their wits could be sharpened by discussion in a more beneficial manner than mere book-cramming. Referring to the Vivisection Act, he maintained that it had incalculably retarded the progress of medical science in this country. The old Act for the prevention of cruelty to animals was all that was really required to protect the lower animals from wanton cruelty. On the motion of Dr. Dobie seconded by Dr. Lundie, a hearty vote of thanks was awarded to the lecturer.

"COMBE TRUST" LECTURE.—GLASGOW.—Professor George Buchanan delivered the fourth of the series of lectures under this trust, on the 31st ult., in the City Hall, Glasgow. Dr. Buchanan took for his subject "Surgical Emergencies and their Management—an Ambulance Lesson." In the outset Professor Buchanan insisted on the necessity of a knowledge of the proper treatment of persons who received injuries in our public thoroughfares. His opinion of the intelligence of persons who frequent crowded thoroughfares seems to be a very mean one, for he laid down the rule that if a person "fell out of a window, or off a roof, the first thing to be done by one of the bystanders, was to take him into some place where he would not be killed by the passing traffic; but if a person was injured in the country, it was best to leave him where he fell." He insisted on policemen undergoing ambulance drill, and that every constable that passed the ambulance drill satisfactorily should have his pay increased, and be preferred when promotion was going. The professor put the volunteers in uniform, through ambulance drill, on the platform, who showed how to treat the injured until the arrival of a doctor. Dr. Buchanan recommended small quantities of whisky as a stimulant in cases of depression from injury. He exhibited also, the framework of the human body by means of skeletons and diagrams. We are beginning to fear, almost, the extinction of the medical profession, in Scotland, as the result of this spate of lecturing. "Professor Coates," Phrenologist, Glasgow, is in the midst of a rival series of "Health Lectures."

CLASS OF CLINICAL SURGERY (EDINBURGH).—Professor Annandale opened his class of clinical surgery on the 31st ult., in the Edinburgh Royal Infirmary. The subject of the opening lecture was the "Diagnosis and Treatment of Surgical Diseases and Injuries." At the commencement of his address he referred to the new hospital, a building of which they might all be proud, and to its opening by the Queen. The hospital had been visited by many distinguished medical men, who attended the International Congress, and had been declared by them to be the finest hospital they had ever seen. In intimating the arrangements for conducting the class, the Professor adverted to the fact, of which he said he was very proud, that he had the honour of conducting the largest class of clinical surgery in this country. This made the arrangements for teaching diagnosis as it should be taught, matters of anxiety and difficulty; but if the students would only

attend regularly and take advantage of the facilities which would be afforded them for learning, he had no doubt that the result would be satisfactory to all concerned.

PROFESSOR MACLAGAN'S CLASS OF MEDICAL JURISPRUDENCE.—Professor MacLagan delivered the inaugural address of this course, to a large concourse of students, on the 31st ult. The Professor was accompanied to the rostrum by Professors Sir Wyville Thompson, Muirhead, and Mackay, &c. Professor MacLagan, after remarking on the close relationship between the Faculty of Law and that of Medicine, went on to speak of the antiquity of medical jurisprudence, which, he said, was said by some to be traceable to the Mosaic dispensation; but though that was not very distinct, there were some traces of it in classical times, though it were few and far between. It was truly not till the present century that it could be said to have been brought to such a condition as to merit the confidence of the profession and the public. It was in 1807 that the first professorship was founded in any British University—that of Edinburgh. The Professor then said, that he had heard a great deal of outpourings of late against vivisection, which he had treated with due disgust. He did not belong to that section, well knowing that without such experiments there would have been many miscarriages of justice. The occurrences of deaths, of which the cause could not be with certainty traced, could by the same drugs, or what might be found in the body or amongst the excreta of the poisoned person, being administered to the lower animals readily produce the same effects in the animals as in the human frame, and thus the cause of death could be accurately ascertained.

ABERDEEN—THE RECTORIAL CONTEST.—The students of the University of Aberdeen are now in the thick of their Rectorial Contest, the candidates being, as we formerly announced, Drs. Alexander Bain, formerly Professor of Logic and English Literature in the University, and Sir James Paget, of London. The contest on this occasion is not ostensibly a political one, both the candidates being Liberals, and the opposing parties profess to be supporting their respective champions purely on grounds of personal fitness for the office. Dr. Bain's adherents ground their support on the ex-Professor's long connection with the University, his great eminence as a philosopher, and his acknowledged position as an enlightened and able advocate of University reform; while Sir James Paget's admirers wax eloquent over his exalted professional position, his great experience and influence of University matters, particularly with reference to medical study, and his advanced views on University reform. Objection is taken to Dr. Bain on the ground of his alleged materialistic views, and while this is more insinuated than openly avowed there is no doubt that it will affect the vote to some extent. It was expected by Sir James Paget's proposers that he would command the entire support of the medical students, but the most prominent of these have associated themselves with Dr. Bain's adherents. Several meetings have been held by the opposing parties, processions have paraded the principal streets, and visited the houses of the more popular Professors, while there have been one or two nocturnal pilgrimages to the residence of Dr. Bain, who had to appear in response to clamorous demonstrations for a "speech." The doctor has refused to make speeches, and his usual advice to his enthusiastic admirers is to go home and "grind," a bit of advice that is not absolutely acted upon by the majority of the students. The election takes place within Marischal College Buildings next Saturday at eleven o'clock.

Correspondence.

CONSULTATION WITH HOMCEOPATHS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the letter of Dr. Wyld in your last issue are to be found some remarkable statements.

1. He "finds some diseases best treated by similars and some by contraries." Might I ask, is Dr. Wyld a homœopath and yet such a heretic as regards Hahnemannian? And can he tell us how he manages consistently to alternate two physiological principles, one of which must be false if the other be true? But I suppose he is one of your pay-your-money-and-take-your-choice class of practitioners to whom such principles are indifferent.

2. He says that consultations are generally to satisfy anxious relatives, and "not to obtain new light." They are especially for prognosis and the medicine to be prescribed is "the last and least important" factor in a consultation. Allow me to say that a consultation held for no other purpose than to hoodwink anxious relatives, in which new light is not wanted and the treatment of the dying patient is the "last and least" consideration, is a fraud, alike disgraceful to the consultor and consultee.

3. He says that he has no difficulty in obtaining "not only surgical but medical assistance from the first men in the profession." You will do an immense public service if you will obtain from Dr. Wyld the names of those whom he considers "the first men in the profession," and send them a copy of Dr. Wyld's letter with his *naïve* statement of the objects of his consultations with them. In my humble opinion, if any physician were known to sell himself to practise so disreputable a sham as that indicated by Dr. Wyld he would deserve richly to be drugged out of association with honourable gentlemen.

A more plain spoken and unblushing *exposé* of homœopathic practice never was penned than that to which Dr. Wyld has inadvertently given utterance.

Yours, &c.,

ONE WHO TRIES TO BE HONEST AND FINDS IT DIFFICULT.

HYPODERMIC INJECTIONS AS A PROPHYLACTIC IN CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—You did me the honour to publish, on May 12, 1880, a suggestion on the prevention of cholera. It was to the effect that if cholera appeared in a regiment, ship, gaol, &c., every one not affected should be hypodermically injected with a solution of quinine, arsenic, and muriatic acid.

Dr. Cameron's paper in your issue for October 19th, refers to the success of Dr. de Lacaille, of Rio, in treating yellow fever by hypodermically injecting phenic acid. This success seems to give reasonable analogy for trying my suggestion in cholera. Between the years 1860 and 1870 I made eight voyages in the East Indian emigrants from Calcutta to the West Indies. I carried hypodermic apparatus to carry out my idea, but no epidemic of cholera happened in either of my voyages. Since then I have often sent the suggestion to India and China, but have never seen a report of its trial. The method might be fairly tried in the actual disease, as also as a prophylactic.

Seeing that cholera is at this time so fatal to the troops in the Punjab, I venture to ask you to allow me to again draw attention to the possible or probable good which might result from the hypodermic injection of the combined quinine, arsenic, and muriatic acid, or of phenic acid.

Yours truly,

WILLIAM H. PEARSE, M.D.

Plymouth, November 2, 1881.

"THE DOCTOR IN THE WITNESS-BOX."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am sure very few members of the profession have read, without pain, the severe comments of Baron Downe on the evidence of Dr. Kelly in the case of The Queen and Peter Duff, and the pity of it is that few will say that the

judge's observations were undeserved. I saw, in yesterday's *Daily Express*, a letter from Dr. Kelly, in which, of course, he puts forward, in the best light, what he has done in connection with the case. His justification amounts to this, that on the day before the inquest, he received a summons from the coroner to attend and give evidence, and this he considered an injunction to him to proceed, and make a post-mortem for himself, in anticipation of an order from the coroner to do so. Surely, in a case of such importance, he ought to have waited to have the coroner order a post-mortem, and to leave the dead body undisturbed and unexamined till the inquest actually commenced, when there would be ample opportunity of making the closest investigation of the injured parts, with the help and supervision of other skilled witnesses. Well, Dr. Kelly did not choose to act in this way, but made an examination of the injured parts in anticipation of the coroner's inquest. He attended before the coroner, and acquiesced in the opinion that the butcher's knife produced could have caused the fearful wound of which poor Constable Daly undoubtedly died. Subsequently Dr. Kelly found some grit in the portion of the skull he removed, and then he came to the conclusion, on very slight data, that death was not caused by the knife. Dr. Kelly claims some credit for himself that he attended at the commission to give evidence in accordance with his later views, but it would appear that his evidence did not go for much, as the jury had no doubt whatever but that the murder of poor Daly was effected by the blow from the butcher's knife. The only doubt they expressed was as to the *proof* that it was Duff's hand inflicted the wound.

I am, Sir, yours, &c.,

F.R.C.S.I.

4th November, 1881.

A MODEL FEVER-DEN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—Permit me to give an emphatic contradiction to the report of the Sanitary Committee to the St. Marylebone Vestry that at a recent interview with the committee I stated I had no charge to bring against the sanitary authorities. What I did say was that I did not blame individuals, but the system pursued for the past, for the failure the sanitary authority of the parish (in other words the Vestry) to prevent the epidemic of typhus fever (still spreading), and to arrest it immediately after its outbreak. There have been forty-one cases in all, with six deaths up to the present.

Typhus being at once the most contagious and the most easily preventible of diseases, the sanitary authority ought to have suppressed the epidemic more than a month ago, and thus saved several lives. Had I not stepped in, at some detriment to health and private practice (keeping up only with the aid of professional assistance, constant Turkish baths, extra diet, and the non-use of stimulants), and discharged the duty the vestry neglected, the cases would have numbered hundreds, and the deaths at least twentier. Typhus cannot survive fresh air, and the removal to the excellent hygienic conditions of Homerton Fever Hospital has saved probably seventeen lives that would have been lost had the patients remained in their insanitary houses. Of the cases so removed a number ought to have been attended to by the vestry. I had nothing to do with these, but had not the heart to see them die without a chance of life. The paupers are the care of the guardians, and right well do these gentlemen fulfil their trust, but no one seems to care whether struggling ratepayers who are not paupers live or die. In March last, from a non-pauper case of small-pox, which was not removed by the vestry, eleven cases occurred in Charles Street. I also told the committee that their professed disinfection was but an outside cleaning of the cup and platter, and was a delusion and a scare. Where attempted it was practically valueless, and I instanced two cases where no attempt was made. One was a man who was allowed to sleep in the infected bed from which a case had been sent the week before. The other was the poor woman on whom the inquest was held, and who slept and died on the infected bed from which her child had been taken seven days previously.

About nineteen years ago there was an outbreak of typhus fever in the same street and neighbourhood, when the relieving officer (then called "inspector") and the district medical officer caught the disease and died. The sanitary authority ought to have at once remedied the insanitation, but after re-

peated subsequent epidemics of contagious diseases the sewerage from the houses is still semi-stagnant and defective, and one house is actually built over a privy, which latter ventilates between the boards into the inhabited room above.

Let me bear, after repeated personal inspection of my cases in the typhus wards, ungrudging testimony to the excellence of Homerton Fever Hospital (the floors of which are so clean that a dinner could be eaten off them), and to the efficiency and skill of the superintendent, Dr. Collie, the medical and nursing staff. As I told the committee, if they would only distribute handbills and other information among the inhabitants of the healthfulness and comfort of Homerton Hospital, much prejudice would be removed, and their own sanitary efforts much aided.

I cast no reflection on my friend, Dr. Blyth, and his staff, or even on the vestry. The traditional conservatism of the *ancien régime* has been too much for them; but I venture to appeal to the latter intelligent and spirited body to immediately reorganise their system, and systematically ascertain the sanitary condition of the whole parish. By so doing they will earn the respect and gratitude of the entire community.

I am, your obedient servant,

NORMAN KERR, M.D.

Grove Road, Regent's Park, N.W.

Nov. 4th.

THE VACANCY ON THE SENATE OF THE ROYAL IRISH UNIVERSITY

CREATED by the death of Dr. Hayden, of Dublin, which will not be in the gift of the Lord Lieutenant of Ireland—as other such appointments have been, but will be filled up by Convocation. That body will consist of those of the Convocation of the Queen's University who choose to apply for a share in the management of the New University, together with the members of the existing Senate. We venture to remind those upon whom the selection of a Senator will rest, that surgery is altogether unrepresented in the executive of a University which is to give degrees in surgery and supervise a surgical curriculum.

This omission to recognise the second great division of the medical art, was one of the multitudinous muddles of Mr. Lowther, when Chief Secretary, and the sooner the wrong done to surgery is remedied the better for the University itself.

THE COUNCIL OF THE IRISH COLLEGE OF SURGEONS.

THE election to the vacancy caused by the death of Dr. McClintock has been fixed for Saturday next. We believe that Dr. Nixon will not present himself at this election, Mr. Butcher being a candidate, and receiving the support of an influential body of the Fellows. Mr. Kendal Franks and Dr. Carte are probably the only claimants who will contest the seat with Mr. Butcher.

THE Duke of Westminster, who is President of the Westminster Hospital, has endowed that institution with a Scholarship of twenty guineas for second year's students, to be annually given to the student in the Medical School who shows the greatest proficiency in anatomy, physiology, and histology.

A PATIENT upon whom Mr. Spencer Wells performed excision of a cancerous gravid uterus on Oct. 21st is, we are informed, progressing most satisfactorily towards recovery.

DR. J. BRAXTON HICKS, F.R.S., has recently been elected an Honorary Fellow of the American Gynaecological Society.

Literature.

A TREATISE ON THE MATERIA MEDICA AND THERAPEUTICS OF THE SKIN. (a)

THIS work is another of "Low's Library of Standard Medical Authors," and is a good practical treatise on a very important subject. It consists of two divisions, viz., the materia medica and the therapeutical aspect of the subject. The former comprises a careful and conscientious selection of dermatic remedies from the American, British, German, French, and other pharmacopœias. The remedies are arranged in alphabetical order, and, under each heading, details are given as to the ways, nature, and use of every remedy, along with references to the several pharmacopœias from which they are derived. The therapeutical portion begins with a general introduction, and some remarks on diathesis; from whence it passes to a description of the leading features of all ordinary skin diseases. These descriptions are given in alphabetical order; and, without going into the lengthened details of Hebra or even of Fox, present a very fair picture of the affections in question. They are illustrated with woodcuts of instruments, of the various parasites, &c., &c.; and to the busy practitioner, who would wish to read a good account carried up to the present day of any skin disease, and then quickly work through all the remedies calculated to be of benefit, this volume will be much more practically useful than more pretentious treatises. Of course, both have their respective places but, it is not always remembered that many practitioners pass a life of great physical toil, and must have information in a handy form, and always ready for reference. Dr. Piffard's book exactly fits this groove, and concludes with a copious formulary, a good bibliography, and a very complete index. We strongly commend it to our readers.

LIFE ASSURANCE.

WE have before us a small pamphlet on the all important subject of Life Assurance, which is now being very widely circulated by Mr. F. A. C. Hare, consulting actuary. (b) Mr. Hare very rightly claims that, whether as a provision simply for survivors (ordinary assurance), or for survivors in case of premature death, and for one's own declining years, in the event of longevity, there is no form of investment that will bear comparison with life assurance in one of our leading companies, combining as it does the three grand requisites—Certainty, security, and profit. Those that assure, base their calculation on certainty, "Death," while those that rely on other modes of accumulation are trusting to uncertainty—"Life and Prosperity." With regard to ordinary assurance it is shown, by means of a carefully constructed table that the rate of interest to be realised on the annual premiums paid to a first-class office returning good bonuses is quite per cent. Even where the life assured lives to an advanced age, while in the event of premature death it ranges from 100 to 3,000 per cent. The benefits arising from an endowment assurance are illustrated by instancing the case of a gentleman, aged 38, who insured in 1853 for £1,000 (with profits), payable to himself on attaining the age of sixty, or to his representatives in case of prior death, upon which policy the bonuses were:—At the end of 1854 an addition of £60, in 1859 £110, in 1864 £120, in 1869 £190, and in 1874 £210. He lived to attain 60 years, and in 1875 received £1,690, having paid twenty-two premiums of £46 10s. 10d. each, or £1,023 18s. 4d., while his family had been secured in the sum of £1,000 (with gradually accumulating profits) from the very day the assurance was effected.

Mr. Hare points out that these results are only to be looked for in connection with the most careful and economical management, hence the great importance attaching to the selection of an office. An intending assurer in making this selection can hardly expect to receive any assistance by direct application to the offices, as it is not to be supposed that a manager would extol any other company above his own. The companies' agents are evidently in the same position, with this

(a) "A Treatise on the Materia Medica and Therapeutics of the Skin." By Henry G. Piffard, M.D. 8vo. Pp. 351. London: Sampson Low, Marston, Searle, and Rivington. 1881.

(b) London: F. A. C. Hare, 111 Finsbury Park Road, N.

further drawback, that being chiefly engaged in other businesses, and possessing little or no knowledge of assurance matters, they could not, if they would, give any reliable assistance in conducting a comparison between the various companies. Such men but rarely understand the workings of their own office, much less those of all others. Indeed, although by Cave's Act it is required that all life assurance companies make full periodical returns to the Board of Trade, yet, owing to their valuations being made, some at the end of every one, and some at the end of every three, five, seven, or ten years, it is necessary to wade through no less than ten formidable blue books to get at the figures of all, and when collected it requires considerable actuarial skill to draw accurate comparisons between them. This is very simply, and yet conclusively shown, in the pamphlet before us on pages 35 to 40. To use Mr. Hart's own words "among so many competing companies each in turn offering 'special advantages,' intending assurers have long experienced the want of an actuary, unconnected with any particular office, to whom they might apply for assistance in forming an independent selection, the importance of which cannot well be over-estimated, seeing that the net cost of assurance, in the case of an average life, is quite 30 per cent. less in some offices than it is in others."

Space will not permit of our following Mr. Hare through his explanations of the various ways in which life assurance may be applied by all classes, viz., in securing marriage settlements, in providing for the replacement of a deceased partner's capital, &c., &c., neither can we do more than mention the very useful hints contained in the chapter on the "Selection of an Office," and the interesting information given under the head of "Bonuses;" suffice it to say, that before assuring, our readers cannot possibly do better than to obtain Mr. Hare's pamphlet.

RHEUMATISM: ITS NATURE AND PATHOLOGY, AND ITS SUCCESSFUL TREATMENT. (a)

IT would be the merest commonplace to dilate upon the extremely unsatisfactory position which the therapeutics of acute rheumatism have occupied up to the publication of Dr. MacLagan's paper upon the salicin treatment in the *Lancet* of 1876. Every class of remedies and appliances, often of a very contradictory character, were in turn recommended, but with results most uncertain. Sometimes, severe cases did well under any or almost no treatment; but too often a grave attack of rheumatic fever resembled a conflagration in a town with no fire brigade, and burnt itself out, leaving the affected tenement permanently injured, if not destroyed. In fact, with the exception of blistering the involved joints (p. 190) or the affected pericardium, which really did good, there was practically no treatment satisfactory to the physician. We have tried salicin for the last few years, and with excellent results; and also its artificially produced congener Sodium Salicylate, with effects less satisfactory. The leading difference between them appears to be that whereas the willow alkaloid can be given safely, in almost any doses, the salt frequently disagrees, even in moderate quantities. It is hardly necessary to add, that Dr. MacLagan's present work is the result of the experience which he has had since 1876; and is an extension of his well-known paper. He undertakes, by the use of salicin in large doses, *coup sur coup*, to reduce the temperature and pain without delay; to render the attack a question of a few days; and to prevent involvement of the cardiac apparatus. There is no doubt that his treatment has accomplished this, and has thus abolished one more of the *opprobria medicinae*. He continues the salicin in small doses for a period after the cure, until the whole *materia morbi* has been destroyed. This is the only part of his book which is not yet fully demonstrated; for we cannot as yet entirely assent to his views that acute rheumatism, like ague, is a miasmatic disease and produced in a similar manner. He brings a startling array of facts to back up his theory: we do not deny it; in the language of his own jurisprudence, our verdict is "not proven." Speaking of salicin, Dr. MacLagan gives a curious letter (p. 258) from a South African hospital surgeon showing how discoveries are often postponed by want of vigilant observation. This gentleman writes that in the year 1861, he was called to attend the wife of a Dutch Boer suffer-

(a) "Rheumatism: its Nature and Pathology, and its Successful Treatment." By T. J. MacLagan, M.D. Medium 8vo. Pp. 333. London: Pickering and Co. 1881.

ing from severe acute rheumatism, and he prescribed the usual remedies. Two months afterwards, the woman walked into his surgery, perfectly well; and upon his expressing his satisfaction, bluntly informed him that his medicine had done her no good. She added that she had been at once relieved by their Caffre shepherd, who had administered large quantities of infusion of the green tops of young willows. On local inquiry the South African practitioner discovered that this was the ordinary and successful native remedy. The publication of Dr. MacLagan's paper in 1876 brought it back to his mind; but it is much to be regretted that the observation was not communicated to the profession in 1861, when salicin was a rather undervalued drug, principally used for adulterating quinine; from which it is difficult to distinguish it. Polarised light is the simplest test. A useful advance in practical medicine would have been thereby much accelerated.

Obituary.

DR. DOMVILLE, C.B.

THE medical officers of the Navy, and the Naval Service generally, will learn with sorrow and regret the death of Dr. W. T. Domville, C.B., Inspector-General, in charge of the Haslar Hospital, which took place on Oct. 21st., at the age of fifty-seven. The services of this officer extend over a period of thirty-seven years, and we feel that it is not too much to say that all who knew him esteemed and respected him alike for his devoted attention to his duties, his amiable courtesy, and the enviable example his life gave to the dignity of the medical profession in the Royal Navy. Dr. W. T. Domville had obtained the position of Senior Inspector-General, and there is little room for doubt, had his life been spared a little longer, the highest office in the medical branch of the Navy would have been conferred upon him, and at his funeral all the honours due to his rank were zealously observed. Dr. Domville entered the Navy in May, 1842, and served one year in the Royal Naval Hospital at Plymouth. In 1843 he was appointed to H.M.S. *Burydice*, and served on the North American and West Indian Stations three years. In 1846 he was appointed to H.M.S. *Excellent*, and in 1848 to Greenwich Hospital, where he had originally entered the medical profession in the lifetime of his father, Deputy Inspector-General of that hospital. Promoted to the rank of surgeon in 1852, he joined in February H.M.S. *Resolute*, for service in the Arctic (under the late Admiral Sir Henry Kellett, K.C.B.), and was mainly instrumental in the discovery, and rescue of the officers and crew of H.M.S. *Investigator*. He remained in the Arctic regions three summers, and two winters, and returned with all the Expedition in October, 1854, when he was appointed to do duty with the Royal Marines at Woolwich, where he served till July, 1855, when appointed to H.M.S. *Agamemnon*, Captain, now Admiral Sir Thomas Pasley, Bart., K.C.B., in the Black Sea, and was present at the taking of Kinburn and Sebastopol. In 1857 he was appointed Staff-Surgeon of H.M.S. *Indus*, flag-ship of the late Admiral Sir Houston Stewart, G.C.B., on the North American and West Indian Stations. In 1860 he joined H.M.S. *Nile*, flag-ship of Admiral Sir Alexander Milne, Bart., G.C.B., for service at Bermuda Hospital, where he had charge of French invalids from Mexico, and received the thanks of the Emperor of the French, as well as a case of surgical instruments. He returned to England after an absence of seven years in 1864, and was then appointed to H.M.S. *Fisgard*, at Woolwich. In June, 1866, Dr. Domville was promoted to the rank of Deputy Inspector-General of Hospitals and Fleets, having served continuously (with the exception of ten months on half-pay) since his entry into the service; he was at once appointed to the charge of the Naval Hospital at Malta, and remained there for five years, and returned to England in October, 1871. In 1872 he was appointed to the Royal Naval Hospital at Plymouth, and served there until promoted to the rank of Inspector-General of Hospitals and Fleets in February, 1875. In November, 1877, he was appointed to the Royal Hospital at Haslar, where he continued to serve until the date of his untimely death, from disease, it is believed, contracted in the performance of his duty, as head of that establishment.

Dr. Domville was made Honorary Surgeon to the Queen in November, 1872, and Companion of the Order of the Bath in May, 1879. He received the "Arctic," "Crimean," and "Turkish" Medals, and to him the Service looked forward

with confidence and satisfaction, as the Director-General of the Naval Medical Department.

H.R.H. the Prince of Wales on hearing of Dr. Domville's serious illness, with his accustomed consideration and kindness, requested his sincere sympathy to be conveyed to the sufferer, and, although arriving too late to be communicated to him, will ever be prized by his surviving widow. Dr. Domville both in public and private life, ever won the affection and respect of all with whom he came in contact, and his fine handsome figure, genial smile, and kindly word for all, will ever be remembered by those who knew him. The expressions of sympathy received from all quarters during his last illness, bear testimony to the widespread grief his death has occasioned, and as evidence of the esteem in which he was held officially, and in consideration of his public services and the circumstances attending his untimely death when in charge of Haslar Hospital, the Admiralty has decided to allow his widow a special rate of pension.

DR. BREWER, LATE M.P. FOR COLCHESTER.

BY the sudden death of Dr. William Brewer, the metropolis loses one who was foremost both in suggestions and practical work in all that pertained to sanitary matters. As Chairman of the Sanitary Committee of the Board of Works, he took an abiding interest in everything that tended to bring London to its present state as the healthiest city in the world; and at the meeting of the Board on Saturday last, the Chairman of the Board, Sir James McGaral Hogg, took occasion to pass a high eulogium upon the high moral and intellectual character of the deceased, a vote of condolence to his widow being subsequently passed. Dr. Brewer also occupied the position of Chairman of the Asylums Board for many years past, and for several years he represented Colchester in the House of Commons. He took his M.D. degree at St. Andrews in 1834, his membership of the London College in 1841, to which latter he was elected Fellow in 1872. Although possessed of high attainments, he rarely committed his views to paper, so that medical literature can boast of but little enlightenment in this direction. He was often urged by friends to give to the profession the results of his rare opportunities and ripe experience, but being of a naturally reticent disposition, he passed out of the world a unit in that vast community which is "content to hide its light under a bushel." His character in this respect is best exemplified in the closing sentence of the last speech we heard him utter, viz., "We are in measure content."

DR. DAVID FOULIS, OF GLASGOW.

WE deeply regret to have to record the unexpected death of this popular and accomplished medical man, which took place at Glasgow on Oct. 31st. Dr. Foulis began his medical studies at an early age, but before completing them he was induced to accept an appointment as a tea-planter in India, where he remained seven years. He afterwards returned to finish his medical curriculum, and it was only in 1873 that he finally graduated. After this he spent two years in hospital work at home and on the Continent, not beginning practice until about thirty years of age, when his thorough professional education and practical experience stood him in good stead. Shortly afterwards he became pathologist to the Glasgow Royal Infirmary. While studying in Vienna he had paid special attention to diseases of the throat, and shortly afterwards commencing life in Glasgow, the successful performance of one of the most complicated operations in surgery, the extirpation of the larynx, at so early a period of his career at once established his reputation as a bold and skilful operator, and he was rapidly attaining a solid position in practice. His recent appointment as dispensary surgeon at the Royal Infirmary insured that he would obtain the command of wards at an early opportunity, and no one doubted that, with such a field and the qualifications he possessed, a highly distinguished future lay before him. He has died at the early age of 35 years, one of the many victims which our profession supplies to the dangers incidental to the discharge of our duties. Dr. Foulis had occasion lately to perform two operations in cases of diphtheria during which he contracted the disease, which ended fatally in the course of a week. He was a man of independent mind, and as a surgeon was distinguished by readiness in device, boldness, and self-reliance. Naturally reticent, he did not appear much in general society, but he was per-

sonally held in high esteem by an extensive circle, and inspired a feeling of deep affection in the few who knew him best.

Royal College of Surgeons of England.—The following gentlemen, having passed the required examination, received the Diploma in Dental Surgery at a meeting of the Board of Examiners on October 28th:—

Headley, Harvey Parry, Oxford.
Hedley, William Snowdon, M.R.C.S., Army Med. Depart.
Mason, Charles Browne, Exeter,
Richardson, Francis, Derby,
Turner, William Arthur, Chichester.

NOTICES TO CORRESPONDENTS.

MR. E. JAMES.—In many such cases no structural changes are discoverable, and dogmatic utterances on the invariable existence of lesions of the nervous matter are not only "unsafe," as you suggest, but actually erroneous. The question of molecular disturbances of course remains, and you will find no authority to oppose the view that such alterations, which are truly physical changes, are not producing factors of the phenomena peculiar to the various nervous conditions. Dr. Gowen has just now published, through Messrs. Churchill, a volume "On Epilepsy," to which you may confidently turn for full scientific details on the point raised in your letter.

A MIDDLESEX STUDENT.—You cannot do better. Mr. Hy. Morris's work will serve your purpose excellently, and an appeal to him personally will, we are sure, be at once met by a willing response.

MR. E. R.—Sorry we cannot yield to your request, the subject being most unsuitable for our columns.

AWKWARD POLITENESS.—A certain physician, whose name shall be unmentioned, was called to visit a lady living at a considerable distance from him. After continuing his calls for some time, she expressed fear that it would be inconvenient for him to come so far on her account. "Oh, madam," replied the doctor, innocently, "I have another patient in the neighbourhood, and I can thus kill two birds with one stone."—*Detroit Medical Journal.*

NUMBER 9.—It was altogether due to a misconception, but the fault was not committed on our side. The contents were, though hardly suitable for publication, sufficiently authentic to serve the purpose originally intended, that usually of confirming the suspicion aroused by the letter. Many thanks for all your trouble, and for the cases which shall receive early insertion.

DR. JOHNSON.—See leading article in to-day's issue, in which your views are embodied. If occasion arises for calling in the services of others friendly to the cause of science, your suggestion shall receive full consideration. At present, however, there is nothing better than a mare's nest to be discovered.

A. G. Y.—We are much obliged, and will remember the offer when the time arrives to avail ourselves of it.

AMNON.—Probably the "Diseases of Women" by Dr. C. West, the new edition of which owes much of its success to Dr. Mathews Duncan's able assistance. Other works are, Thomas's valuable handbook and Atkinson's "Gynecology," the latter (published by Baillière, Tindall, & Cox) being the most likely volume for your purpose.

MEDICAL TEMPERANCE ASSOCIATION.—We are asked to announce that on Tuesday next, at the quarterly meeting of this Association in the rooms of the Medical Society of London, a paper will be read by Dr. Norman Kerr "On the Use of Stimulants in Workhouses." The meeting will be held at 4 p.m., and all members of the profession are invited to the discussion.

DR. CHALMERS.—The subject has been so frequently referred to of late in our columns that we would rather leave it for the present.

MR. BILLING.—We do not prescribe. You are quite right to refuse further payments to the quack mentioned, but we cannot take up your case. Consult any respectable practitioner in your neighbourhood.

F.R.C.S.—The matter is referred to in another column.

A COUNTRY PRACTITIONER.—We have made inquiries and find the book has been out of print for twelve months. The author advertises a second edition "in active preparation."

JENNER.—The following graceful tribute to the immortal Jenner appeared in the last number of the *Cincinnati Lancet and Clinic*:—

"Within this tomb hath found a resting-place
The great physician of the human race,
Immortal Jenner! whose gigantic mind
Brought life and health to more than half mankind.
Let rescued infancy his worth proclaim,
And lip out blessings on his honoured name;
And radiant beauty drop one grateful tear,
For beauty's truest friend lies buried here."

THE SOCIETIES.

HUNTERIAN SOCIETY.—This (Wednesday) evening, at 7.30 o'clock, Council Meeting.—8 o'clock, Dr. Robert Barnes, "On Antiseptic Midwifery and Septicæmia in Midwifery."

ROYAL MICROSCOPICAL SOCIETY.—This (Wednesday) evening, at 8 o'clock, Mr. B. Willis Richardson, "On Multiple Staining of Animal and Vegetable Tissues."

CLINICAL SOCIETY OF LONDON.—Friday, Nov. 11, at 8.30 p.m., Mr. Golding Bird, "On Cases of Gastrostomy."—Adjourned Discussion on Mr. Reeves's Paper upon "Two Cases of Malignant Stricture, in which Gastrostomy was performed."—Mr. Clement Lucas, "On a Case in which a Pebble was removed by Tracheotomy from the Right Bronchus."—Dr. Mahomed and Mr. Cripps, "On Two Cases of Direct Transfusion of Blood for Hemorrhage in Typhoid Fever."

Vacancies.

Belgrave Hospital for Children, London, S.W.—House Surgeon. Salary, £30, with board. Applications to the Hon. Sec. by Nov. 23.
Birmingham General Dispensary.—Resident Surgeon. Applications to the Secretary on or before Nov. 16.
East Sussex, Hastings, and St. Leonard's Infirmary, Hastings.—Assistant Surgeon. Applications to the Secretary not later than Nov. 1.
Portsmouth Lunatic Asylum.—Assistant Medical Officer. Salary, £21 with board. Applications to the Chairman of Committee at the Asylum by Nov. 14.

Appointments.

ALLAN, J., M.A., M.D., Medical Superintendent of Leeds Union Infirmary.
FERGUSON, D., L.R.C.P., L.R.C.S. Ed., Medical Officer of the Llanwy District of the Newtown and Llanidloes Union.
FLOWER, F. J., M.R.C.S., Medical Officer for the Warrminster and Corley Districts of the Warrminster Union.
GROOM, H. T., M.R.C.S., House Surgeon to the Clinical Hospital for Children, Manchester.
GROVER, J. F., M.R.C.P. Ed., M.R.C.S., Medical Officer for the Social Division of the Third District of the Newhaven Union.
HARVEY, W., M.R.C.S., Medical Officer for the Teignmouth District of the Newton Abbott Union.
HODGES, J., L.S.A. Lond., House Accoucheur to King's College Hospital.
HOLTHOUSE, E. H., B.A., M.R.C.S., House Surgeon to King's College Hospital.
JELLY, E. A., M.B., C.M., Resident Physician to Saughton Hall Private Asylum.
JENKINS, T. G., L.R.C.P. Ed., M.R.C.S., Medical Officer to the Workhouse of the Ruthin Union.
JOHNSTON, R. M'K., M.B., C.M., L.R.C.S. Ed., Resident Physician to the Royal Hospital for Sick Children, Edinburgh.
LITTLE, H. S., M.R.C.S., Medical Officer of the St. Giles's District, Reading Union.
MADDISON, W. T., M.R.C.S., House Physician to King's College Hospital.
POTTS, E., M.R.C.S., Medical Officer for the Tarporley District of the Nantwich Union.
RABBITT, S., L.S.A. Lond., Assistant House Physician to King's College Hospital.
RABY, J., L.R.C.P. Ed., L.R.C.S. Ed., M.R.C.S., Medical Officer for the Totnes District of the Totnes Union.
SCHOLEFIELD, G. E., M.B., Medical Officer for the District of Skirrow and the Lower Division of Warley, Halifax Union.
SEATON, E., M.D., M.R.C.P. Lond., Physician to the Nottingham General Hospital.
SELLERS, J. W., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Barrow-upon-Soar District of the Barrow-upon-Soar Union.
SNOWDEN, A., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Hutton District of the Stoke Newington Union.
TURNBULL, A. E., M.B., C.M., Medical Superintendent of the Fife and Kinross District Lunatic Asylum.
WEST, J. A., M.R.C.S., House Surgeon to King's College Hospital.

Births.

ORTON.—Nov. 3, at 30 Lower Phillimore Place, Kensington, W., the wife of George Hunt Orton, F.R.C.S., M.B. Lond., of a son.

Marriages.

PURCELL—REEVE.—Nov. 1, at the Church of the Sacred Heart, Leam, Edward G. Purcell, M.D., of Limerick, to Anne D. Reeve, also and adopted daughter of Mrs. E. Allen, of 165 Highway New Park, N.

WHEELER—TASKEE.—Nov. 3, at St. George's, Hanover Square, Leam, John Wheeler, M.D., C.M., of Pembridge Gardens, W., to Jane Tasker, of Gibraltar.

Deaths.

BREWER.—Nov. 2, at his residence, 21 George Street, Hanover Square, London, Dr. William Brewer, Chairman of the Metropolitan Asylums Board.

COURTENAY.—Nov. 3, Emma, eldest daughter of the late C.R. Courtenay, M.D., and last surviving sister of F. B. Courtenay, M.R.C.S. of Chandos Street, London, aged 76.

EDIS.—Oct. 10, at Santa Barbara, California, F. P. Edis, F.R.C.S. Surgeon-Major in Her Majesty's Indian Army, in his 29th year.

FOULIS.—Oct. 31, of diphtheria, at 191 Hill Street, Glasgow, David Foulis, M.D., aged 35.

FOWLER.—Oct. 30, at Marland Place, Southampton, Robert Stans Fowler, M.R.C.S., aged 77.

GEOGHEGAN.—Oct. 27, at Milton, near Portsmouth, Edward G. Geoghegan, Assistant Medical Officer, Borough Lunatic Asylum, youngest son of the late Dr. T. G. Geoghegan, of Dublin.

MACDOUGALL.—Oct. 30, at Jordan Lane, Morningside, Edinburgh, Alexander MacDougall, L.R.C.S. Ed., in his 78th year.

MACKERTICH.—Oct. 27, at Fitzroy Square, London, Surgeon-Major S. Mackertich, M.D., 5th Punjab Infantry, aged 44.

OLIVER.—Oct. 6, of yellow fever, at Barbados, John Richard Oliver, Surgeon A.M.D., late of Abbeyleafe.

RANDALL.—Oct. 30, at the residence of his father, Dr. J. Randall, Nottingham Place, W., Surgeon-Major J. G. Randall, of Westwick, aged 36.

SOLEY.—Oct. 30, at Windsor, T. Ap Preece Soley, M.R.C.S., L.S.A. Lond., aged 35.

TEMPLE.—Nov. 3, at 1 Belvoir Terrace, Cambridge, Alfred Robert Temple, M.R.C.S., in his 71st year.

REMARKS ON DISSOLUTION OF THE NERVOUS SYSTEM, AS EXEMPLIFIED BY CERTAIN POST-EPILEPTIC CONDITIONS.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P., F.R.S., Physician to the London Hospital, and to the National Hospital for the Epileptic and Paralyzed.

(Continued from page 401.)

SECTION XIX.—*Re-statements with Qualifications.*

The wording of some sentences in the first paragraph Section 17, is to be carefully noted. We are not to be understood as meaning that a person after an epileptic fit is always more affected by external circumstances, &c., than he was when well, for manifestly a man comatose is less so. All that is meant is, that those of his nervous arrangements next lower than those exhausted are more affected, what is left of him, much or little, is more easily influenced. So in one way the post-epileptic patient is less influenced and in another way more influenced by his surroundings; in so far as his negative condition goes he is not influenced at all, in so far as his positive condition goes he is too much influenced.

Reminding the reader of what was said in Section 13 I would qualify the foregoing by the admission that the positive condition in the cases of slowly effected dissolution may not be unduly modifiable or only slightly so in the way spoken of in this and the preceding Sections.

The reader will observe that we have now spoken of three factors in Dissolution (1) "Depth" of the dissolution; (2) Rapidity with which it is effected; (3) Influence of local bodily states, &c. These we shall later on consider at length, along with another factor, "the person in whom the dissolution occurs."

SECTION XX.—*Re-statement of Differences betwixt the Negative and Positive Elements in the First and Second Degree.*

Figuratively speaking, and yet almost literally, the patient who has undergone dissolution is at once "less

himself," and "too much himself," speaking more in detail, he is too little his *highest* self and too much his *lower* self. In one way he is less affected by externals in another way he is more affected by externals (Section 19). We may say that he suddenly *ceases* to be enough his highest self, and at once, or soon, *becomes* too much his lower self. The obvious illustration of this dictum is by cases of different degrees of drunkenness. The patient, after an epileptic seizure, is in the strictest sense another person differing in two ways from his ante-epileptic self, from what he was before the paroxysm I mean. We must never forget this double difference when using the pronoun "he." There are two "he's," one standing for the man before his fit, the other for the man after it. They are two different persons. Although, as we may put it, they are in the same skin, they do not look or act like the same person; they are not the same person. The normal "he" does not remember what the other "he" did after the fit; the normal "he" is held irresponsible by legal tribunals for the other "he's" doings. As suggested (Section 12) we must estimate the value of pronouns carefully. The word "he" is, a highly technical term in spite of its apparent simplicity, as is evident if we consider what "he" means in "He remembers so and so." "He" stands in that sentence for the whole person subjectively, whilst "remember so and so" stands for the whole person objectively. We might put it, as it were, diagrammatically thus: "*He* remembers so and so," and "*He remembers so and so.*" Every proposition implies such duplication—into subjective and objective.

The "he" after the fit is different from the "he" before the fit by a certain *minus* and a certain *plus*. The second "he" is objectively *minus*, and subjectively *plus*. There often is after a slight epileptic seizure (our first degree) a defect of object consciousness—so far negative—and positively remains of object consciousness with sometimes increase of subject consciousness, that is, "a dreamy state"—so far positive. In other words, "the positive condition" is itself duplex; it is an abnormal mental state; one imperfect by deficit and imperfect by excess.

As the last paragraph may be thought a little obscure, especially since further terms (subjective and objective) are introduced, I must illustrate what is said. But before that can be properly done, some important terms have to be defined, and some preliminary matters have to be discussed.

SECTION XXI.—Various Uses of the Terms Subjective and Objective.

The words subjective and objective are used in different senses by different medical men. Hence I must say how they are to be used in this work. First, let me state several contrasted ways in which they are used, in which ways I shall not use them.

(a) Subjective is sometimes used for psychical states in contrast to the correlative nervous states, which latter are then called objective. According to this view, colour is subjective, and the correlative activity in certain central nervous elements is objective.

(b) Subjective is sometimes used for faint psychical states in contrast to vivid psychical states, which latter are then called objective. Thus, to think of a brick is to have a subjective state; to see a brick, is to have an objective state. This amounts to saying that an image or idea arising during strong central changes peripherally initiated is objective, and that an image or idea arising during slight central changes, not peripherally initiated, is subjective.

(c) Subjective is sometimes used for vivid mental states in contrast, not to states of the organism, but to the environment, which latter is then called the object. Thus, the mental state in seeing an object, is subjective; the "real thing itself" (I mean here the popular real thing, not "the thing in itself,") is objective. According to this use of the terms, we have (subjective) an "idea of sugar;" the "sugar itself" existing outside with its qualities (sweetness, &c.), is objective, and yet, somehow, notwithstanding its having qualities, is altogether a material thing. This doctrine seems to imply that we have (subjectively) an "abstract idea of sugar," an idea of it divested of sweetness, particular colour, and other attributes, in relation to a sort of direct knowledge (objective) of the particular "real thing" outside us—particular lump of sugar—which is, itself, hard and sweet. On this view part of our mind is outside in the "real thing," literally taken the whole of it is outside, for an "idea of sugar," divested of all attributes of sugar, is nothing. Another way of verbally stating this view, is to say that in perception we see real things (perceive them) by aid of a faculty of perception; this is like saying that we walk by a faculty of locomotion.

(d) Subjective appears to be sometimes used for both mind and organism together in contrast to the environment, which latter is then called objective; thus an idea in the brain (compare "ideational centres," &c.), is subjective, the "real thing" (*vide supra*) outside, of which the idea is, is objective.

(e) Sometimes the term subjective is used for a nervous change only, and the term objective for the "real thing" outside (*vide supra*), supposed to correspond to it; thus a certain change in the cerebral centres answers to what is a brick, existing with all its qualities, redness, &c., outside us. This view is, verbally, that the whole of the mind is outside ourselves, for changes in cerebral centres are physical processes.

(f) Occasionally the two terms are used each in different senses in different parts of the same argument. By this plan verbal simplicity is introduced into accounts of mind body. By using the term objective sometimes for nervous changes, sometimes for "real objects" outside, and sometimes for vivid mental states, in contrast to faint mental states, and by using the term subjective sometimes for all mental states, in contrast with nervous states, sometimes for faint psychical states in contrast to vivid psychical states, and sometimes for "ideas of things" in contrast to "real things" outside, a pseudo-practical view of the relation of the anatomy and physiology of the nervous system to psychology is taken, and an un-

real clearness is given to some very complex problems which disease presents us with. On such schemes, to give an example, a sensation is either a psychical state, or a state of the nervous system, as convenience dictates. Starting with the periphery, active states, of sensory nerves become sensations in sensory centres, and in the highest centres are compounded into ideas, and from these the most elaborate mental states are easily traced. (a) The real crudity of the process is veiled by technicalities; a state of a sensory nerve first becomes in some nervous centre, an "unconscious sensation," and next turns into a "conscious sensation." The criticism on this is that "unconscious sensation" is contradictory, and "conscious sensation" tautological.

Considering how different are the significations given to the two terms by medical men, it is allowable for me to define them for my present purpose, without assuming that my definition is superior to some of those above given.

(To be continued.)

THE INTIMATE NATURE OF ZYMOTIC POISON.

By JOHN DOUGALL, M.D., &c., F.F.P.S.G.,

Lecturer on Materia Medica in the Glasgow Royal Infirmary School of Medicine. (b)

THIS subject is ever of the most vital importance and absorbing interest, not only to all medical men, but to all humanity. About 50,000 to 80,000 persons die annually from this poison, and allowing one death out of every twenty who suffer from its effects (for the great majority of those attacked recover), it follows that, roughly speaking, about 1,600,000 individuals in our country are poisoned yearly by this substance, and about twenty years ago their numbers were much higher. Now this frightful sickness and mortality is not confined to Britain alone, but prevails more or less, generally more, in every community in the world. I am not using any mere figure of speech nor hypothesis, either as regards the cause or number of these deaths, while the quantity of persons attacked, but who recover is a pretty close approximation. I mean what I have stated, that such a probable amount of sickness, and so great a number of deaths, are not the result of disease at all but of poison; while the Registrar's returns are my authority for this zymotic death-rate.

What then can be the nature of the potent agent that plays such terrible havoc with human, and it may be added in many cases with lower animal, life? An agent that causes an amount of mortality yearly in Britain alone, not surpassed probably by all the battlefields of Europe in twenty years. An agent which spares neither the learned nor illiterate, the rich nor poor, the young nor old. An agent which often shows us how contemptible and impotent are all our powders and potions, and numerous devices to thwart in the smallest degree, its dogged course and fatal issues. An agent which in the softest and subtlest manner, steals into the blood always,

(a) This is "getting the mind out of the body." (By the way, to my great surprise, a distinguished physician, whose opinion I greatly respect, tells me that this is what I try to do. I can only repudiate holding such an opinion, and appeal to what I have repeatedly said here and elsewhere.) The mind being got out of the body, the next thing is to endow it with "faculties," with will, memory, &c.; this being done, here is a sort of reversal of the process mentioned in the text. Now psychical states produce physical states; a person moves his hand by an act of volition; the will produces contractions of muscles. We start at the periphery with states of sensory nerves, and in the highest centres get mental states out of them, and these set agoing other psychical states, which end at the periphery in muscular contractions. These psychologico-materialistic theories are not really clear; they hinder progress in neurology.

(b) Lecture delivered in the Glasgow Royal Infirmary on October 26th.

contaminating its pure current, and frequently tainting it to death by its keen virulence. Of course it is obvious that it cannot be any even of the most active poisons known to the chemist or toxicologist. It cannot, *e.g.*, be phosphorus, arsenic, strychnia, atropia, aconitia, prussic acid, &c., &c., that is clearly quite out of the question. What can it be? Is it a vegetable, animal, or mineral product? Is it solid, liquid, or gaseous? What is its taste, or is it tasteless, is its odour pleasant or offensive; or is it odourless? Is it opaque or transparent, coloured or colourless, amorphous or crystalline, acid, alkaline or neutral? Can it be produced synthetically, and if so, how and from what? Is it a simple or complex body? Has it any known reactions with chemical agents, by which it can be isolated, or other distinctive properties by which it can be known; or is it only recognised by the manner in which it disturbs the healthy functions, or produces death? When and by whom was it discovered? Why is it called zymotic poison? Has it any antidotes? In short, has it been seen at all? Such are the chief questions in regard to any alleged lethal substance, which naturally occur to those versed in the chemistry and toxicology of the more common poisons; but at present I cannot do more than answer these in a general manner and without regard to the order in which I have put them. Zymotic poison then in no way resembles any other toxic substance, excepting that it is, as already indicated, a deadly poison. It differs, on the other hand from all other such bodies in respect that it cannot be confined in stoppered bottles, measured nor weighed, and in particular it differs in this important point, *viz.*, that while the actions of other poisons are confined to the individual affected, it renders the persons it poisons poisonous. For example, as you know, one may attend closely on a patient suffering from a fatal dose of opium or strychnia, without danger of becoming narcotised or tetanised by the opium or strychnine which the patient has swallowed. But one who has not survived the special form of zymotic poisoning with which a person is affected could not attend him with impunity. Because he might poison his attendant, his nurse or doctor, *ray*, even his friends or neighbours in the same house or land, with the identical virus by which he himself is affected. His body is for the time being an alembic in which a special virus is elaborating and multiplying enormously by an apparent destructive distillation of the blood and secretions, so that the tissues may literally be soaked and the body be enveloped in an atmosphere of virulent infection. The blood, saliva, breath, sweat, urine, *fæces* and epidermos may all be saturated with it. This poison is named from the Greek word *ζυμη*, or leaven, and a person under its influence is held to be in a condition of zymosis or fermentation. It was so denominated because, when it enters the body of an individual susceptible to its influence, it gives rise to phenomena very analogous to those caused by the addition of yeast to a substance capable of fermentative change. Supposing, for example, there is added to an aqueous solution of honey, or of grape, or any other sweet fruit juice, a single cell of the yeast plant "*torula cerevisiæ*." This speck of matter is about the size of a human red blood corpuscle and hence only visible under the microscope. Supposing further, that this solution is kept at a temperature of about 70° Fah., then in a few hours, or at most a day or two, from the single yeast cell, millions are produced so as to make the liquid turbid, and form a frothy scum at the top and a sediment at the bottom. During these changes the temperature of the fluid is increased and carbonic anhydride largely evolved, until latterly, the heat begins to reach the normal, the evolution of gas to cease, and the solution is now found to have lost its sweet taste, and changed into a mixture of alcohol and water incapable of further fermentation. Now for the analogy between this process and that of zymotic poisoning. Supposing I were to wet

the point of a needle with lymph from the body of a small-pox patient and push it under the skin of a person who had neither been vaccinated nor suffered from small-pox; then a thousand chances to one that in a few days, perhaps hours, the recipient of the lymph feels out of sorts, has nausea, vomiting, headache, thirst, backache, a high pulse and hot skin. In about three days after a papular eruption appears on the body which soon changes into blebs or vesicles. These may be few or many, separate or confluent, but the clear and apparently homogeneous fluid which they contain, as the identical specific infective nature, as that with which the needle was wetted. The minute portion on the needle having now multiplied in the blood of the person inoculated, to an enormous extent, how I need scarcely say, that the symptoms just enumerated are those of small-pox, and that the lymph introduced into the blood by the needle, was "zymotic poison." The putting of the yeast cell into the sweet solution and of the minute portion of small-pox lymph into the human body are both cases of pure infection, and the zymotic phenomena evoked thereby are almost perfectly analogous. You observed 1. That the saccharine solution was susceptible to the action of the yeast and the human blood to that of the lymph. 2. The extremely minute portions of yeast and of lymph employed. 3. The rise of temperature in both cases—the sweet solution becomes abnormally warm, the small-pox patient highly fevered. 4. The great multiplication of yeast in the sweet solution, and of small-pox lymph in the blood. 5. The yeast frothing to the surface of the fluid, and the small-pox eruption forming lymph bubbles or vesicles. 6. Both are infectious—a cell of the new yeast would cause fermentation in a susceptible fluid; a speck of the new lymph would cause small-pox in a susceptible person. 7. The sweet solution is no longer capable of fermentation, from the chemical change it has undergone in fermenting; the small-pox patient is no longer susceptible to small-pox, also from some chemical change produced in the body by that poison. 8th, and lastly. The sweet solution will ferment, as it were, spontaneously, that is, without putting yeast cells into it intentionally, because such cells are constantly floating about and fall on its surface; so may a person take small-pox spontaneously by inhaling air containing that specific poison. These are both cases of pure infection, though in neither is the infecting agent visible.

Now, I have chosen small-pox to compare with fermentation because it is a typical species of the genus zymotica, the other chief members of which are:—scarlatina, measles, diphtheria, typhus and enteric fevers, and cholera. These affections are generically related in respect that they are caused by a something which either enters the blood from without, or is, as seems in some cases, generated therein spontaneously, and re-produces itself to an enormous degree, usually rendering the secretions and excretions of the affected person poisonous, if inhaled or swallowed by a healthy person susceptible to their action. Also that they commonly only make one attack, and always cause a high pulse and increased bodily temperature. Their specific differences are so remarkable and distinct that each may be fairly considered as caused by a separate form of virus. For example, a medical man may be called to see a patient who sickened two days before, and now complains of thirst, and headache, is fevered, prostrate, the eyes suffused, the tongue probably dry, furred, and studded with red points, the throat swollen and tender, and the skin covered with an exuberant efflorescence of bright scarlet dots, and he pronounces the case scarlatina. Or the patient may have swelling of the eyelids, with eyes red, watering, and intolerant of light, sneezing, dry cough and hoarseness, with difficulty of breathing; on the fourth day of the fever the skin gets covered with small red dots which coalesce into slightly raised crescentic blotches, and the case is diagnosed as measles. Or the patient may have stiffness about the neck, slight diarrhoea,

nausea, pain on swallowing, salivation, foetid breath, the throat covered with specks or patches like damp, dirty wash-leather, symptoms indicating diphtheria. Or the patient may have frequent chills, a soft pulse, dry brown tongue, constipated bowels, heavy, flushed, smoky countenance, stupor, prostration, wakefulness, delirium. About the seventh day of these symptoms the skin is covered with irregular spots, of a dusky or mulberry hue, which at first disappear on pressure, are slightly elevated, but soon become persistent, symptoms showing the case to be typhus fever. Or the patient may have pains in the limbs, great weakness, loose bowels, with very offensive stools which may contain blood, glazed dry tongue, with ammoniacal breath; a pale languid face with a hectic flush on each cheek, clear eyes with dilated pupils and the mental faculties unaffected. About the eighth day a few elevated and isolated rose-coloured dots are probably found on the abdomen or chest, vanishing on pressure, appearing in successive crops which last two or more days, symptoms clearly indicating enteric fever. Or lastly, the patient, quite well a few hours before, may have severe diarrhoea, with evacuations like rice-water, cramps in the limbs, causing the muscles to be hard as wood, or contracted into knot-like masses, the circulation and respiration impeded, the nose, tongue, ears, breath, and extremities icy cold, the lips and general surface blue or livid, the eyes sunk, the pupils contracted and fixed, the complexion muddy, and the features pinched, the whole body shrunk and intensely prostrate, perhaps death taking place before the doctor has time to prescribe for what is too obviously a case of Asiatic cholera. But zymotic affections have other characteristics besides these enumerated which place their specific nature beyond doubt. For example, a person suffering from, say, typhus, only shows symptoms peculiar to the special virus of typhus, and should he infect another, it will be with typhus only. In other words, each zymotic virus produces a group of symptoms entirely peculiar to itself, and a crop of poison identical with the original poison. Just as a crop of wheat or oats is of the same nature as of the seed sown by the farmer. Another strong proof that the various zymotic affections are caused by different poisons is, that one attack usually confers immunity from subsequent attacks of that special poison, but does not exempt from being assailed by each of the other members of the zymotic group consecutively. Moreover, into whatever part of the body specific infective matter is introduced, it produces, so far as known, symptoms characteristic of itself, only, and not of any other form of virus.

Proceeding now to consider "what is zymotic poison?" I may at once say that this problem has hitherto all but baffled the skill and eluded the researches of the most profound thinkers and patient investigators in medical science. It has been fertile in numerous but fruitless discussions; it is susceptible of the most plausible but fallacious solutions, of the most ingenious, fascinating, but vain speculations, and has been the incentive to numberless of the most delicate, protracted, and even dangerous, but withal valueless experiments. All the reasoner's logic and the experimenter's results regarding the nature of specific infection have, until perhaps lately, practically ended in vague theories and conflicting hypotheses.

Such being the case I can only mention a few of the chief points and considerations on which observers have dwelt, and of the principal conclusions at which they have apparently arrived. There are two theories regarding the nature of "zymotic poison," viz., the "Germ Theory," and the "Physico-Chemical Theory." Believers in the germ theory hold that zymotic diseases are caused by microscopic living organisms, which, entering the blood, set up morbid changes characteristic of the special organisms, which may be scarlet fever germs, small-pox germs, cholera germs, &c., &c., each infectious disease having its special organism, germ, or ferment. The germ theorists also affirm that putrefac-

tion is the result of germs, which they allege, in densely populated places especially, are floating in myriads in the atmosphere, and only need a congenial soil, such as dead organic matter, or a weakly organism, to make them reproductive. Hence germs require morbid conditions for their existence. Now, in order that you may fairly comprehend the theory, I must say a few words on putrefaction. If a portion of clear fresh wine, blood serum, or juice of flesh be freely exposed to the air for a day or two at a temperature of about 70° Fah., and then a drop of it examined by the microscope, it will be found swarming with organisms called bacteria, measuring about 1-40,000th of an inch. The fluid is now turbid, foetid, neutral, or alkaline, but never acid. On the other hand, if portions of any of these liquids be boiled in separate glass flasks for about a minute, and during ebullition the necks of the flasks stuffed with cotton wool, and the steam allowed to issue through it a short time; and if the flasks be now set aside, their contents will be found months or years after pure and unchanged. But if at any time the cotton be removed from one of the flasks, then in a day or two its contents will putrefy, while those of the other flasks remain fresh and clear. Now these experiments show that it is not the air which causes putrefaction, because the cotton wool is pervious to air; neither can the cotton obviously have any antiseptic effect on the fluid, nor chemical action on the air passing through it into the flask. Nor can it be the boiling of the fluid which keeps it fresh, as such fluids in ordinary circumstances soon putrefy after boiling. This process is resorted to for the purpose of destroying that in the fluid which would cause it to putrefy if it were not boiled, even although the neck of the flask were stuffed with cotton. The cause of putrefaction must hence be something in, but distinct from, the air, and this substance is obviously filtered by the wool from the air entering the flasks. Now, according to the germ theorists, the something consists of the germs of bacteria and their allies, vibriones and monads, but chiefly of bacteria, which swarm in all putrid liquids. This, however, must be considered a mere inference, as no power of the microscope can detect the germs of adult organisms so minute as 1-40,000th of an inch, if they bear, which they doubtless do, the same relation in size to the parent organism as in most other cases, either in the vegetable or animal kingdom. Compare, e.g., the minute nautilus-like seed of the opium poppy, 200 of which only weigh a grain, to the entire plant and its numerous capsules as large as oranges; or compare an acorn to an oak, or the human germ, measuring about 1-250th of an inch, to a man weighing sixteen stone; or the germ of the bull and horse, which are said to be even smaller than that of man, to the adult animals.

The origin of these micro-organisms was a few years ago made the subject of numerous interesting experiments by Dr. Bastian, of London, who asserts that he has thereby demonstrated that life may arise anew from dead matter. I shall not dwell on this point, but merely state that Bastian obtained results that seemed to prove that life arose in certain rich nitrogenous fluids after they had been heated from 260° to 302° Fah. while hermetically sealed in glass flasks, a temperature, I am convinced, however his results may be explained, that no living things, germs or other, could resist. The fact, however, remains that minute organisms teem in all putrefying solutions, whatever way they get there, and are absent in all solutions not putrefying, whatever way they don't get there; and while the germ theorists assert that they are the cause of putrefaction, and that their functions in nature are malignant, the physico-chemical theorists generally believe that they are the result of putrefaction, and that their functions in nature are beneficent. The chief points adduced by the germ theorists in support of the malignant function of such minute organisms, are:—1st. That they are present in all putrid, and absent in all

fresh or healthy, organic matter. 2nd. That many diseases, both of animals and plants, they allege, are caused by parasites and fungi. The opponents of this theory, of which I am one, hold that all such organisms are the result of the morbid conditions of their habitat. 1st. Because that, whether bacteria, parasites, or fungi, they are only found on the parts of animals or vegetables of lowered vitality, or in their dead tissues. 2nd. That by strengthening the vitality in living, or arresting decay in dead parts, they disappear. 3. That when present in infectious matter it loses its power to infect, as observed in small-pox and vaccine virus. On these grounds the functions of such organisms are held as beneficent, and Prof. Owen, with that large grasp of intellect which marks all he says, calls them "Nature's Scavengers," for maintaining the salubrity of our atmosphere, and "Nature's Invisible Police," for arresting the fugitive organised particles, and turning them back into the ascending stream of animal life.

(To be continued.)

CYPRUS REGENERATE.

By W. HY. CULLEN, M.D.
Nicosia, Cyprus.

The Climate.—The year 1878 as all Cypriotes have told me, was both exceptionally hot and unhealthy. Without dwelling at any length on the strange misconceptions that generally prevailed, at the time of the annexation, as to the nature of the climate, and the fears that were so freely expressed of the effects of a residence there, it may not be undesirable to record the experience obtained during the last two years. The extent to which our soldiers suffered is not at all surprising when we know the conditions under which the occupation was conducted. The men were hurried on shore at Larnaca, which during the summer is especially unhealthy, on account of the exhalations from the salt lake near it, and the barren treeless character of the country round, huddled into single bell tents in the hottest month of the year, the thermometer standing in them at 110°, with indifferent food, and as if to make matters worse, camped near a marsh. In fact it might be truly said, made ill to order, though in the neighbourhood of Limassol, excellent localities were available, with abundance of running water, and trees affording ample protection and grateful shade from the burning sun.

That the climate is not *per se* unhealthy is satisfactorily proved by the fact that many employes, both military and civilian, who with their wives have been here since the occupation, have enjoyed as good health as if they had been all the time in England, and whose ruddy countenances are a sufficient refutation of the supposed unhealthy climate of the Island.

Vital Statistics.—Statistics, in the proper sense of the word do not exist, as no attempt has ever been made to register births and deaths, and even among the Christian part of the population it is impossible to obtain any trustworthy information, as in answer to my inquiries of the Archbishop I find that there are no church registers, every effort having been made to conceal the birth of males as far as possible, in order to avoid the payment of the tax for exemption from military service. Now that a Sanitary Commissioner has been appointed, these deficiencies will be gradually corrected, and Dr. Barry has lost no time in having meteorological observatories erected here at Larnaca and Kyrenia, to be followed by others at Limassol and Famagusta. At each of these places district surgeons are appointed to attend all who may apply daily at the Government Dispensary, and thus in time a very accurate knowledge of the prevailing diseases will be obtained from the Registers kept of the numbers of sick and the nature of the diseases under treatment. After the taking of the Census in April, a medical certificate of the cause of

death will be made compulsory in all cases, and where outlying villages are too far off to be visited by the district surgeon, the duty of registering both births and deaths will devolve on the Mucktar or head man of the village, though in all cases of death by violence or supposed poisoning the District Commissioner accompanied by the surgeon, will make the necessary inquiries.

Hygienic Conditions, Diseases, &c.—Before the occupation, a large open ditch, about twelve feet deep, and which served as the cloaca maxima, ran through a part of the town. This has now been covered, and a good road runs over it, while the same process of conversion of all open drains into sewers is being carried out. The following details have been obtained in answer to numerous inquiries, and will sufficiently enable anyone to form a fair estimate of the hygienic qualities of the town as a place of residence. Typhus, which, as may be supposed, was very frequent before the occupation, has disappeared, and though there appear to have been several cases, I have not heard of a single death during the last year. Of diphtheria one case occurred, but was not fatal. Phthisis, if not absolutely unknown, as asserted by Sir S. Baker, is exceedingly rare, the cases that have occurred during the last few years were not, as I have been told, hereditary, but as one informant told me "acquias," i.e., the result of some neglected disease of the lungs. Scarlet fever, measles, and whooping cough, appear to be unknown. Ague prevails more or less throughout the Island, though not of a malignant type, though at Morphose, towards the west end of the Island, and at Famagusta, at the east, the people suffer more severely, as the marshes are so nearly on the sea level that drainage will be very difficult. No objections are ever made to the periodical visits of the Government vaccinator, and I believe it will be made compulsory ere long, first in the towns, and subsequently throughout the Island. Ophthalmia is very general among the poor, owing to the dust prevailing during the summer, and aggravated by dirt and neglect, though the water supply is abundant.

The Military and Police.—The 20th Regiment, which left their encampment at Limassol last autumn, lost only one man in the nine months of their stay, and that from a disease previously contracted in Halifax. Among the 32 women belonging to the Regiment, there were 11 cases of fever, and 1 of diarrhoea, and among the 36 children, 9 cases of diarrhoea and 9 of fever, 2 children having died from the effects of burns. The mortality in Larnaca town last year was 22 per 1,000, and 18 for the country district, which is about the rate here for the last six months. The months of October and November, as is so generally the case throughout the east, affording nearly half the total number of deaths. In the Police Force, numbering 700 men, and composed of both Turks and Greeks, two deaths took place last year from pneumonia in men who had previously suffered from the same disease. All men declaring themselves unfit for duty, are obliged to enter the hospital, and more than 25 per cent. suffer from syphilis in some of its many forms. A suitable hotel for the reception of invalids is in contemplation at Limassol for the winter, and what will be of perhaps more importance a summer retreat or sanatorium on the slopes of Troodoo, about 4 to 5,000 feet above the sea level, in the midst of scenery of unrivalled beauty, and in a climate which will allow an invalid, even the most delicate, to live continually in the open air. A lady, threatened with phthisis, and who came out from England to Cyprus more than a year ago, has lost all symptoms of disease, and appears to be in excellent health.

There will be an election for an assistant physician to the Richmond Hospital, Dublin, on the 17th inst., in the room of Dr. Reuben Harvey, who has resigned.

Clinical Records.

MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.

Brief Notes of Operations.

Under the Care of Mr. LAMBERT H. ORMSBY,
F.R.C.S.

Lecturer on Clinical and Operative Surgery.

(For these notes we are indebted to Mr. FRANK CAMPBELL.)

OPERATION I.—Reduction of Sub-Glenoid Dislocation of Humerus. (3 weeks' standing).—Patrick B., *æt.* 60, was admitted into Meath Hospital on September 4th, from Co. Cavan, suffering from a sub-glenoid dislocation of right shoulder of three weeks' standing, is a blacksmith by trade, and is very muscular. Mr. Ormsby having recognised the dislocation, placed the man on a hair mattress lying on his back, on the floor, he determined to apply the plan of the late Mr. White, of Manchester. The patient lying on his back—his shoulder having been firmly fixed by an assistant the affected arm was then grasped by the operator and, in the completely extended position, was then gradually drawn out from the side. Extension during this movement kept up all the time until the extended arm was carried directly over the head parallel with the body. Considerable but steady extension was then exerted, the shoulder being fixed by an assistant when the muscles of the patient appeared to be tired out, the doubled fist of an assistant was then placed in the axilla, and the arm was suddenly brought to the side and then over the chest. After this manoeuvre was repeated on the third occasion the head of the humerus returned to the glenoid cavity. The arm was then bandaged to the side and kept in that position for a fortnight, after which the patient was discharged.

OPERATION II.—Removal of Fibrous Epulis from Lower Jaw.—Ellen H., *æt.* 22, was admitted to the Meath Hospital under the care of Mr. Ormsby, suffering from a fibrous epulis growing from the gum between two decayed teeth in lower jaw. *History*—She stated that she had noticed the growth for the last seven months, and during that time it did not seem to grow very much larger. The growth seemed to be very hard to the touch and was occasionally rather painful.

Operation performed on the 22nd September, 1881. The mouth being kept well open, and by means of a strong knife, pair of scissors, and bone forceps, the growth was carefully separated and completely removed from the gum. Smart hæmorrhage followed which was controlled by pressure of a small quantity of lint steeped in solution of perchloride of iron. The girl made a good and rapid recovery.

OPERATION III.—Removal of large Sequestrum from Femur.—James M., *æt.* 50, was admitted to Meath Hospital on the 18th September, from Roscrea, suffering from necrosis of the lower inner third of the femur. There was a large sinus at the side of thigh immediately above the internal condyle of the femur which gave vent to a large quantity of pus. On exploration with a probe a loose sequestrum was found very deep in the sinus, it was also partially moveable. On the 28th September the patient was placed under the influence of ether, Esmarch's bandage being applied to the limb. An incision, 3 inches long, was made in the situation of the sinus parallel and close to the femoral artery, having carefully divaricated the soft parts, the extent and size of the sequestrum was clearly ascertained, but the dead portion of bone was found to be very firmly wedged above and below that it was hard to remove; however, by means of a long necrosis forceps, gouge, elevator, lion forceps, and bone forceps, the sequestrum was detached, which appeared to occupy two-thirds of the circumference of the bone. A good deal of hæmorrhage took place after the Esmarch's bandage was removed. It was found, however, to be venous, and was controlled by means of pledgets of lint with a well applied bandage. The man made a good recovery, and was discharged November 7th, 1881, to the country.

OPERATION IV.—Tenotomy for Talipes Varus.—An infant, *æt.* four months, was admitted into the Meath Hospital from Co. Kilkenny, suffering from double talipes varus, one foot being much more turned inwards than the other, as is usually the case when the deformity is

double. Mr. Ormsby invariably divides the treatment of club feet into three stages, the Manipulative, the Operative, and the Instrumental. Much can be done by an intelligent mother or an attentive nurse, in the first few weeks after birth, by careful manipulation with the hand. While the infant rests on the nurse's lap, the foot affected should be grasped and firmly turned outwards, and kept so for a few minutes; this should be done constantly in the day, and smart friction should be applied to the inner and outer ankles of the feet affected, by means of the hand. The foot is then in a position for the operative treatment which, in the case of varus, is divided into two stages. The *first stage* consists in the division of the tendons of the tibialis anticus and posticus muscles. The latter tendon need not be divided in every case. When the inversion of the foot is permanently corrected without any pressure of the hand to increase the eversion. Mr. Ormsby then carries out the *second stage* of operative treatment, which consists in the division by tenotomy of the tendo-achillis. By this procedure the heel is brought down on a level with the sole, and maintained in that position by a flat piece of well-padded hoop-iron, weak enough to bend in any direction, and a narrow bandage, after this has been applied for almost a fortnight, changed every day, and reapplied, if possible, so as to avoid pressure sores. The Instrumental line of treatment is then adopted, which consists in the application of a shoe suggested by Mr. Reeves, of London, and made by Mr. K. R. Schramm, of London, and other instrument makers in Dublin at a very moderate cost. In the case of this infant, the tendons causing inversion of the foot were divided first, and a month afterwards the tendo-achillis in each foot was divided, and a Reeves' shoe then applied.

Special.

MEDICINE IN CHINA.—I.

1. *Introductory.*—In the year 1870 the present Inspector-General of Imperial Maritime Customs in China instituted a systematic method by which information was to be obtained and utilised regarding disease among foreign residents as well as natives of that empire. Among other points arrived at, information was solicited as to peculiarities presented at the several Treaty ports in regard to disease in general, and in regard to particular forms of disease, rarely, if ever, encountered out of China. The reports were further to include information as to general health at individual ports; death-rate among foreigners; type, peculiarities, complications of prevailing diseases, and treatment pursued; the relation of disease to season, alteration in local conditions, as drainage, &c., and alteration in climatic conditions; peculiar diseases, as leprosy, and so on; the natural history of epidemics, including their absence or presence, their causes, their course, treatment, and lastly, the fatality of individual outbreaks. Considering the number of places at which the Customs Inspectorate has established offices, the thousands of miles north and south, and east and west, over which these offices are scattered, the varieties of climates and the peculiar condition to which, under such different circumstances, life and health are subjected, medical officers connected with the Customs service were confidently appealed to for their active co-operation in carrying out the intentions of the Inspector-General.

And with what amount of zeal and attention the medical officers thus appealed to, have carried out the important work assigned to them, the series of reports, already published sufficiently indicate. Extending over a period of ten years, they number twenty, the mass of information thus brought together being of the highest value. From these reports then, the following remarks on the subjects to be referred to are taken. As will be seen, the results there

indicated tend, in certain instances, to confirm the correctness of theories which find acceptance in the West; but in other, and no less illustrative instances their tendency has a very different direction.

2. *The Medical Art in China.*—(a) Science in relation to medicine exists not among the native professors of the healing art in China. Even as an "art," medicine holds but an abased position, practised for the most part on no other principle than that of charlatanism. Pharmacy, including the property of drugs, mineral and vegetable, holds a better position, although in its practice, superstitious observances on the one hand, a belief in the direct curative or specific properties of particular substances in relation to particular forms of disease on the other, appear to be the guiding principles held in view. And yet, notwithstanding a manner described as absurd of employing many substances in themselves absolutely inert, long experience and observation have beyond doubt made practitioners acquainted with the application of a large number of remedies of great power and value. Thus, anaesthesia has, for many generations, been obtained locally, or generally as required, by means of certain fungi, or by aconite root. Remedies are obtained from the mineral kingdom, from the animal, but mainly and chiefly from the vegetable. Of the first class are preparations of mercury, nitre, borax, ammonia, potass, soda, the more ordinary metals. Of the second a variety from which it is sufficient to name the bile from bears; hartshorn; gelatine from hides; bezoar from ruminants, bones, moustaichois, and claws of tigers, besides matters far more offensive and objectionable than these. Of the third, the assortment includes an immense number of different plants, several of which are received in our own country, including rhubarb, cubebs, camphor, ginseng (*Panax ginseng*), and so on. It is matter deserving notice that of medicinal plants, the great majority having definite properties are employed for precisely similar objects alike in empirical art in China, and in scientific medicine in England.

3. *Chinese Knowledge of Iodine.*—Iodine and some of its preparations enter largely into native Chinese practice. Chinese works, one in particular—namely, the *Pen-tao*, contains descriptions of the well-known therapeutic properties of several species of sea-weed in the dispersion of hard tumours and goitre, each species having its distinctive character in Chinese. One species is, moreover, prescribed as a diuretic; another as a remedy in "growths of all kinds," in orchitis, and against "any number of demons." Having regard to these and other uses to which sea-weed as containing iodine has been put in China, the report asks, "would it not be advantageous to introduce a powder and tincture of *laminaria* into our public dispensaries, poor houses, &c.?"

4. *The Relation of Insanitary Conditions to Epidemics.*—Throughout the very able reports under notice, many references occur to the condition as regards conservancy of individual cities, and the relation, when any exists, between it and epidemics. The condition of Pekin in this respect, having been minutely described, the reporter thus continues: "With all our filth, dirt, and smells—and people in the west can form no notion of what they are, for they defy description—there is wonderful immunity even from fevers. If bad smells alone created fevers, there ought to be no immunity from these diseases." Then follows a footnote to this effect: "The sanitary legislation of western cities is based upon the one idea that disagreeable and offen-

sive odours are necessarily deleterious to health. The condition and mortality of Pekin would rather seem to explode this belief. Many diseases prevail here, as in the west, without this reputed cause, and the cause exists at all times here without producing such diseases."

5. *Prisons in Canton.*—The state of the prisons in Canton is thus described: "Prisoners kept in separate enclosures, 30 or 40 confined in spaces of not more than 15 or 20 feet square, surrounded partly by posts with interspaces for the admission of air, the men crowded like herds of sheep, the picture of filth, rags, and misery, the stench that issued from these dens insupportable." In such conditions we wonder not that fever was rife, that new comers, unaccustomed to the poisoned atmosphere, often die; but read with surprise, and in disaccord with presumptions suggested by western hygienic principles, "that some of the old prisoners live and thrive under such circumstances."

6. *Climate.*—The subject of *climate* is frequently discussed in the reports before us. The writers record their views as to the influence of climatic conditions, physical features of the country, and food upon the development of the permanent character of the race or races inhabiting it. But food and diseases of a race themselves depend upon physical characters of a country, as also the adaptability or otherwise, of immigrants to conditions in which they are placed. Some valuable remarks occur in the observation so often made, but chiefly by persons without individual experience under circumstances to which they refer—namely, that climates of evil repute obtained that character undeserved, that in reality they are as healthy as our native lands, and that residents would find them to be so did they assimilate their diet and habits to those of the natives. It is remarked that there is a sophistry about this which deceives some persons. Such sophists do not think of the generations that have passed before the natives' suitability to the climate, diet, and other circumstances has been acquired; of the millions who must have died in the process of adaptation; they do not think that our own constitutions have been formed by a similar process long and elaborate; they try to effect the changes wrought by centuries in the fraction of a generation, and at once. We ought always to remember that we are exotics here, and that we should surely sicken and die if we did not in one way or another try to reproduce the circumstances of the lands in which our constitutions were bred. The true advice is, to make China as like Europe as we can, and by cultivating temperance remain vigorous to resist malign influences when they come.

7. *Mortality of Parturient Women.*—From such statistics as are available, the rate of mortality of Chinese women in child-bed is excessive. The Chinese themselves estimate it at 5 to 8 per cent. on all labours. This circumstance is readily accounted for. Except in the rare instances where spontaneous evolution takes place, presentations of the upper extremity must be fatal to both mother and child. Placenta previa, foetal hydrocephalus, pelvic tumour, distorted pelvis, insuperable rigidity of the cervix, and many other serious complications which demand interference must terminate in the death of the mother. To these are to be added such formidable sequelæ as syncope, secondary hæmorrhage, puerperal peritonitis, uterine phlebitis, and tetanus; whilst abortion in the early months with profuse hæmorrhage, doubtless results in death in many instances.

8. *Some Remarks on Fever.*—Notwithstanding the extremely filthy condition of Chinese cities, ten years ago typhoid fever was extremely rare among natives, if indeed it existed at all, while among foreign residents it only pre-

sented itself in very few instances. Thus, at Canton, in a period of ten years, up to and including 1870, two cases only had been observed among foreigners. But, according to the reporter:—"The natives have no faith in the skill of foreign physicians in the cure of fever, and when taken with it, they do not send for them, nor do they come to hospital to be treated as in-door patients. The fevers seen among the out-door patients are generally intermittents. From native books and physicians we can gather no distinct idea of such a fever as typhoid fever."

The reporter adds:—"Since the sewerage question has been so much in agitation, in connection with this fever, it may be well to mention that in Canton large numbers of the native population are daily using water, and inhaling air charged with impurities of human excreta, apparently with utter impunity."

In their treatment of fevers generally the medicine Chinese practitioners employ, in some cases diaphoretics, diuretics, and at times aperients. In other cases medicines are administered with the intention of subduing fever without diaphoretic action. In adynamic cases restoratives are given; otherwise nourishment is withheld.

In cases of remittent and intermittent fever, it is stated that the Chinese can, to a very considerable extent, cure with their own medicines the cases which quinine cures; also that the rates of recoveries under their native system are very considerable. With reference to this point the reporter states that the prospect is very remote of the Chinese abandoning their own, and adopting European medicines in the treatment of fevers; that they are well satisfied with their own medicines which give a fair amount of success; and that "to show the Chinese the superior efficacy of European medicines we must be able to effect cures quickly and decidedly, especially in those cases where they fail. And this is the very natural, as it is the crucial, test to demand.

(To be continued.)

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

TREATMENT OF POLYPI OF THE UTERUS.—M. Labbé, on Wednesday week, opened a discussion at the Académie de Médecine on the opinions expressed by M. Guéniot at the previous séance on the various methods adopted in the treatment of polypi of the uterus. M. Guéniot pronounced himself in favour of the serre noue. M. Labbé on Wednesday considered that M. Guéniot, in his communication, left an important point in the shade, for it was fully recognised to-day that every slow operation, having for its object the destruction of a morbid production by gangrene or suppuration, should be left aside. It was thus that the ligature was rightly abandoned. However, there was still in existence the elastic ligature, and which still obtains some favour amongst a certain class of eminent surgeons, but M. Labbé could not accept it, for its process is too tedious. Excision should likewise be rejected, as it has the inconvenience sometimes of opening important vessels and thus exposing to hæmorrhage. There is, however, a mixed operation which appeared to him much more acceptable, and which consisted in excision, combined with cauterisation. As for the linear écraseur, he could only understand its employment in cases where the pedicle was easily accessible. But there was another variety of uterine polyp which required attention. It was those voluminous fibrous polypi which were implanted by a large base on the fundus of the organ. The employment of the écraseur in these cases would be highly dangerous, as it has been known to implicate in its loop, the wall of the uterus, and in some cases perforate its substance. He much preferred the galvanic canterry, as the section obtained by this instrument was perfectly bloodless, especially when care was taken not to bring the wire beyond a sombre red. In several cases of voluminous and vascular tumours he had obtained the results by this method. M. Verneuil could not agree with M. Labbé that the écraseur should not be totally abandoned, on the contrary, he considered that since he has been able to hold in one hand the écraseur, and in the other the

thermo-canterry, he never felt the want of any other instrument. M. Gosselin believed that all the instruments in question were good, but he would give the preference to excision with the scissors. Upon fifty operations that he had practised for small polypi of the uterus, he had but one case of hæmorrhage which was easily arrested. He would remind his colleagues that the hæmorrhage from which women who have polypi suffer, does not proceed from the tumour itself, but from the congested mucous membrane. M. Trélat thought that the difficulty did not lie in the selection of the instruments, but in the diagnosis of each individual case. The discussion, which exhausted all the time of the members, was wound up by M. Tillaux, who advised the rejection of the chain of the écraseur, or any other chain in all cases of polypi which do not possess a distinct pedicle.

SARCOMA OF THE LOWER JAW.—At the Société de Chirurgie, M. Tillaux presented a young man who had been first operated on in Canada for a sarcoma of the lower jaw, and occupying the right parotidæan region. The tumour returned and the young man came to Paris and placed himself under the care of M. Tillaux, who performed resection of the bone, in cutting through the centre of the horizontal ramus, and then disarticulated the condyle from the glenoid cavity. The parotid gland was extirpated without difficulty, but the external carotid had to be ligatured. Recovery was slow, but it is now complete. A very interesting point in this case is, that the function of mastication is not in any way compromised. The facial nerve not having been cut, there was no apparent facial paralysis.

QUINTUPLE BIRTH.—A case of quintuple birth has been recorded in a recent number of a medical journal. A woman, *excisée* for the third time, was confined ten hours after the labour set in, of a male infant which presented naturally, a few moments afterwards a second bag of waters broke—a second child following, and in the normal position. A third child was born under the same conditions. The pains ceased for a short time, and on recommencing, gave exit to a fourth child. A few minutes later the fifth made his appearance, bringing with him his placenta and bag of water complete, soon after two more placentas, one large the other small, made their appearance, and then the uterus contracted spontaneously. The five children were well formed, four of them belonging to the male sex. All were born alive, but survived only a couple of hours. They appeared to be six months and a half old (intra-uterine life). The three first children were enclosed in one bag of waters, and the three placentas were joined to each other. The fourth and fifth had each a placenta and chorion separately. The mother made a good recovery.

TREATMENT OF TYMPANITIS.—Tympatitis is a complication of typhoid fever and enteritis, which merits to be treated with care. The late Maurice Reynard prescribed, with great success, the following:—Nux vomica, in powder, six grains; aniseed, in powder, three grains. Mix and divide in two powders, one to be taken in the morning, the other in the evening. M. Reynard also ordered two table-spoonful of powdered charcoal in the course of the day.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 11TH.

The President, JOSEPH LISTER, F.R.S., in the Chair.

FIVE CASES OF CANCER OF THE OESOPHAGUS, IN FOUR OF WHICH GASTROSTOMY WAS PERFORMED, CONSIDERED IN REGARD TO THE ADVISABILITY OF THIS OPERATION.

Mr. GOLDING BIRD presented brief abstracts of these cases, together with one of a case in which the operation though commenced, had to be abandoned, from the occurrence of oesophageal hæmorrhage that threatened immediate death. He pointed out that being a palliative and not a radical operation it could not be judged by bare statistics, for it dwelt with the effect of the disease, not the disease itself. That his cases showed that the chances of giving relief were inversely as the length of time the patient had suffered. The man who lived five months after gastrostomy, was 66 years of age, but had only had symptoms two months. All the others had much longer histories. That gastrostomy of itself was not a fatal and hardly a risky operation, the one case of peritonitis that occurred being due to an accident, the causes of which were not likely to be often met with. That as with most other medical or palliative operations, the patient had the better chance the earlier he was operated upon, and this was especially so in gastrostomy where the surgeon only fed, but the patient still required power to digest; yet he would not withhold gastrostomy even from cases presenting themselves

late in the disease, where starvation was the only prospect, though he thought the anæsthetic added much to the existing share of depression in the patient. He would here, however, modify the usual plan and open the stomach at the time of operating, and give nourishment at once. He believed that he lost two of his cases by not doing this, fearing vomiting, &c., He was distinctly opposed to œsophagotomy as a substitute. Four out of the five cases quoted had the growth in the chest, and therefore would not have been benefited by œsophagotomy, while when the growth is at the cricoid level, it is operating dangerously close to a growth liable to fungate or increase on irritation. Dilation of a cancerous structure high up might be fairly tried, but when in the chest it was, in his opinion, more dangerous than gastrostomy itself.

Dr. COUPLAND related the case of an old woman who suffered from stricture of the œsophagus at a point on a level with the 8th dorsal spine, and who had suffered from dysphagia for eight months. The larynx was quite moveable; a bougie was passed in eight inches from the mouth, but no further, and Mr. Henry Morris, at Dr. Coupland's request performed gastrostomy, the stomach being reached by a vertical incision. The sutures held, and in three days the wound healed. Fluid food was administered, but this running out, finely chopped meat was given and retained somewhat better. The patient died five days after operation. Post-mortem examination revealed extensive disease of the bowels and of the œsophagus, and also that the fistula was situated only one and a half inches from the pylorus, the contracted stomach having displaced the pyloric end considerably. Dr. Coupland thought gastrostomy might possibly give a hope of prolonging life, otherwise dependent on nutrient enemata, but that the difficulty to be encountered arose from the late stage at which, from the extreme objection to operations of the kind entertained by patients, they could be induced to submit to it.

Dr. CAVAFY asked if, profiting by the experience of experimental physiologists, a canula had been inserted into the fistulous openings made into the stomach, as by such means the accident referred to by Mr. Golding Bird might have been averted.

Mr. ARTHUR DURHAM said he had been among the first to perform the operation in this country, and was much interested in it. He had been called on to treat many cases of cancered œsophagus, and he considered patients operated on for this disease fared as well as others of the same class. He could not withhold praise from Mr. Howse for his improved mode of operation in such cases. He considered the unfavourable statistics were due to a late recourse to operation, since patients refuse to undergo it until the time for beneficial results to follow from it had gone past. The idea of opening the stomach was naturally frightful, and similar objections apply to œsophagotomy, a bloody wound in a conspicuous position having great terrors. The danger of gastrostomy, however, had been much exaggerated; provided patient was in good condition, it was a safe proceeding. It could not be denied that œsophagotomy was an ugly operation; but the gullet had often been successfully opened for the removal of foreign bodies. For himself he would refuse to permit a hole to be drilled through his neck into his œsophagus; but he could propose a third alternative, and had at the time, in Guy's Hospital, a female patient who illustrated the certainty attending it. This woman had been for some time dysphagic, owing to an epitheliomatous growth on the back of her larynx. She left the hospital once, but returning in a worse condition, unable to swallow liquids, and supported only by enemata, various operations for her relief were considered. Finally, a small catheter was successfully introduced through the mouth, past the growth, and through it she had been fed for some months, and was still receiving food in the same manner. He considered this patient would have been infinitely worse off had her larynx and pharynx been cut away, and trusting to the plan described, he had adopted it in another similar case with equal success. These examples sufficiently indicated that in some cases at least the œsophagus would tolerate the introduction of a bougie, although the contrary opinion had been expressed at the recent Congress. He recommended a trial of tube-feeding before resorting to gastrostomy or œsophagotomy, and felt sure that the exercise of due caution would minimise all danger from such proceedings. He never hesitated himself to introduce a small tube, and emphatically condemned the suggestion made to introduce them through the nose.

The PRESIDENT suggested that Dr. Coupland and Mr. Durham should embody their remarks for insertion in the Society's *Transactions*.

Dr. DOUGLAS POWELL believed that, however skilful the operation might be performed, there was a danger of injecting fluids, in some cases, into the pleural cavity, as in a case he had recently seen where the malignant growth extended into the bronchus. He had seen a young woman at Guy's Hospital on whom Mr. Bryant performed gastrostomy by oblique incision through which the patient was entirely and easily fed. She had complete control over the opening, through which there was no regurgitation. Any operation, however, in advanced cases was, he thought, out of place.

Dr. GOODHART believed annular strictures were rare. They commonly involved one to two inches of œsophagus; and, in ordinary cases, gastrostomy was the operation he inclined to prefer.

Mr. RAVINGTON thought no surgeon would think of cutting an opening while any chance of passing a bougie into the stomach remained. In Mr. Reeves' case he had tried by all fair means to pass the stricture, but in vain. The case was thus a fair one for comparing the value of the two operations. Wherever no diseased structures were to be encountered he would select œsophagotomy as an aid to reaching the stomach with a bougie, and in cases of localised stricture high up, œsophagotomy or œsophagostomy; but in no case would he think of operating thus while it was possible to pass even the finest tube past the stricture.

Mr. DAVIES COLLEY wished the unfavourable impression as to gastrostomy could be removed. Mr. Howse's mode of proceeding was attended with complete success, the patient surviving for a lengthened period. He had twice done the operation; one patient died of gangrene of the lung, which existed at the time; the other, a woman, long dysphagic, was fed for eight months through a tube inserted into the stomach. The rest thus afforded to the diseased œsophagus led to its improvement, and the patient could afterwards swallow well, and continued to do so, even with solid food. He asked if Mr. Golding Bird had adopted Mr. Howse's operation.

Dr. ANDREW CLARK described the case of a little boy admitted into his ward at the London Hospital with ulcerated œsophagus, due to ammonia swallowed accidentally. After a time he went out, being then able to swallow liquids; but was re-admitted three months later, unable to swallow at all. The surgeons refused to touch the case, and he then endeavoured to introduce a bougie, but failed at first. Subsequently, however, a fine instrument was got in, and after long persisting, with gradually-increasing sizes, the boy was so far relieved that he could eat solid food without discomfort. He wished to know if any special plan was resorted to for making the food introduced into fistulous stomachs easy of digestion.

The PRESIDENT remarked that if malignant disease was found in the upper part of the œsophagus there could be no certainty that it did not extend downwards; his own experience was that it occurred more frequently low down. In all such cases a little prolongation of life is the most that could be hoped for, the triumph of the operation being attained in traumatic cases. He agreed that careful and continued use of a bougie might effect better results than operation. He knew nothing practically of œsophagostomy, but thought it a difficult operation to perform. He inquired if any difficulty had been found in feeding patients through the opening.

Mr. GOLDING BIRD said his dread of accident with the bougie led to his using it in two cases only. He had always operated after Mr. Howse's method. In the case where food passed into the peritoneum, the knife accidentally cut one stitch of the suture, and the stomach also was unduly stretched by the growth above it. He thought gastrostomy had been proved not an unsuccessful operation.

Mr. REEVES was glad to hear the opinions expressed, but was nevertheless not convinced of the inadvisability of his plan of operation. Œsophagotomy was not at all a difficult undertaking. In two of his cases the stricture was annular and small. As cancer might be expected possibly to involve the greater part of the tube, he always cut into the upper part first, and, except when food extravasated, no sloughing ever followed. No difficulty had ever been experienced at the London Hospital in finding the stomach; but when such difficulty existed it might be removed by inflating the viscus through a tube introduced from above. The oblique incision and the double row of stitches, as employed by Mr. Howse, had been suggested seven years ago by Verneuil. Though

statistics were unreliable, yet they tended to show that gastrostomy was more fatal than his operation. He therefore urged that œsophagostomy should first be resorted to, and a tube introduced through the opening for feeding purposes. His experience of treatment of cancer in the rectum, of which he saw not less than two or three every week, and of the absence of all danger from forcible dilatation in such cases, would lead him to proceed unhesitatingly to pass a bougie through malignant growths in the œsophagus. His final conclusions were favourable to œsophagostomy in cases of œsophageal stricture.

Mr. CLEMENT LUCAS explained that Mr. Howse's improvement on Vernouil's operation consisted in adding to that operation by leaving the stomach a few days prior to employing the opening made into it.

Mr. R. CLEMENT LUCAS on

A CASE IN WHICH A PEBBLE WAS REMOVED BY TRACHEOTOMY FROM THE RIGHT BRONCHUS.

A little boy, *et.* 4, sixteen days before admission into St. George's Hospital, was playing with a pebble, and accidentally swallowed it. He was immediately seized with violent paroxysms of coughing and dyspnoea, which lasted for some time, and then passed away. From that time he was usually seized about twice daily with these paroxysms of coughing, which were always accompanied by distressing dyspnoea. During the attacks the face became blue, and the veins prominent and turgid. It was especially on waking from sleep that the coughing became violent. In the intervals between the paroxysms he suffered no distress, and was able to laugh, sing, and swallow without the slightest discomfort. When seen by Mr. Lucas on July 14, 1881, the child was breathing with difficulty, and a physician who examined his chest had heard râles over the right bronchus. The cough was violent, rasping, and jerky, unaccompanied by whooping or wheezing. When the paroxysm came on the child became blue, and almost suffocated. Mr. Lucas further noticed that during the effort of coughing with his finger on the trachea, the foreign body could be felt to rise and strike that tube, and then fall back again. The trachea was opened under Mr. Lucas's direction by the house surgeon, Mr. Wood, and held open by retractors. At this time the child ceased breathing, but was restored by artificial respiration. The coughing which followed failed to dislodge the foreign body. A silk suture was next passed, by means of a semi-circular needle and needle-holder, through the margin of the wound in the trachea on either side. The trachea could by means of these be drawn widely open. The child was then inverted and percussed on the back. The body did not become dislodged till the child was again placed on its back, when a fit of coughing brought it into sight. It was two or three times sucked back by the inspiration which followed after it had been driven up in the trachea, but it was eventually dislodged, and prevented by forceps from re-entering. The foreign body proved to be a hard white pebble about the size of a cherry stone. The after treatment consisted in placing the child in a steam-tent, with moistened lint. For several days the child breathed chiefly through the wound. There were râles in the chest and muco-purulent expectoration. The temperature rose on the third day as high as 102° Fah., but gradually subsided to normal at the end of a week. The child left the hospital well on August 4, the wound being at this time soundly healed. Mr. Lucas remarked that tracheotomy was the only treatment in such cases, as it was highly improbable that the vocal cords, irritated by the presence of a foreign body in the trachea, would allow that body, when of considerable size, to re-pass the rima. Left alone the case would almost certainly after a time have proved fatal. He strongly advocated the use of sutures to draw open the tracheal wound, as being infinitely superior to any form of retractor or dilator that could be invented. The weight of the pebble in this case caused delay in its expulsion. Had it been a cherry stone, as the parents thought, it would probably have been more readily coughed up. Some foreign bodies, as tracheotomy tubes, cannot be expelled by coughing owing to the air passing by or through them. He alluded to a case of this kind that he brought before the Royal Medical and Chirurgical Society in 1877, and said that a narrow-curved forceps was the best instrument to use in such cases.

The PRESIDENT exhibited an improved forceps for removal of foreign bodies from narrow canals, the feature of which was that on being opened the blades occupied less space than when closed.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, NOVEMBER 16, 1881.

“FREE” AND “FAIR” TRADE IN SCIENCE.

In one of his clever speeches at Glasgow recently, Sir William Vernon Harcourt informed his audience with evident pride that he was a “free, and not a ‘fair,’ trader in administration, as well as in commerce.” A Royal Commission has just finished an investigation into the alleged grievances of the medical profession, in respect of medical education and qualification, and as it is at present considering its report, the present may not be an inopportune time to point out to our readers at least one direction in which the Crown encourages neither “free” nor “fair” trade, and that is in the highest of all commercial walks, that of education, and medical education in particular. If there be one possession more than another to which an individual has an inalienable right, it is that which accrues from mental application and culture, and surely of all others he has the most pre eminent right to impart the benefit to others—to make it, in short, a marketable commodity, if he so inclines, in the mart of learning. It cannot be predicated more truly of the grosser articles of commerce that fair competition conduces to the public good than of education, that freedom of imparting knowledge tends to the advancement of science and the benefit of the human race, by calling forth a spirit of healthy

emulation and rivalry on the part of those who assume the important office of public instruction. This is no new theory. Since University monopoly was blindly and ignorantly instituted it has been frequently proclaimed, often with the enthusiasm and commendable emulation of youth, and as often abandoned from sheer despair and disgust at official bondage. In the violent struggle for existence men are too prone to think only of the impediments to the interchange of the material, indifferent to the State thralldom which confines and administers the intellectual.

It was an axiom of Adam Smith that the State should take no cognizance of professional matters; but not only does the State, in matters relating to the medical profession, take cognizance of its intellectual affairs, but it regulates and creates monopolies prejudicial to learning, hurtful to the public, and it makes control of these monopolies the reward of political faithfulness or social accident. It is really difficult to see why the right to impart knowledge should be made a premium on a political garment, or why the obnoxious law of hereditary dictatorship should dominate in the realm of science. For the result of the Royal Commission to which we have referred, timid mediocrity in the Chairs of our Universities trembles; humbler intellectual life aspires to be free. It is not possible within the compass of such an article as this to present but the merest outline of much that seems erroneous in principle in the matter of medical education, as it is certainly at variance with the enlightened promptings of an age which perhaps too blatantly proclaims its intellectual advancement. We trust to be able to present one or two aspects of the question well worthy of, and demanding, attention. At the very outset, it is surely an anomaly that a Government which recognises the competitive system in its Civil Service departments, thereby seeking to secure the fittest occupants of office, should in the matter of medical instruction determine the fitness of the teacher by political predilections, the accident of birth, or the too frequent life long and unmanly subservience to some one to whom accident, and not worth, may have assigned an elevated social position. It is a remarkable truism that in few directions is public indifference more manifest than in that which relates to the instruction of a class of men on whom society is so dependent for so much that makes life tolerable or agreeable, and Arcadian innocence is seldom more faithfully portrayed than in the large class of individuals who indulge the belief that merit determines the possession of an academic medical chair, and are thus so easily charmed by the cabalistic term, "Professor." But the striking aspect of this matter is that the Crown itself distrusts the value of the education thus received by its non-acceptance of the diplomas of the Universities as guarantees of a sufficiently sound medical education for practice in the public service. It virtually proclaims that while students thus educated may be sufficiently competent to practise among Her Majesty's civilian subjects, they are not qualified to practise among Her Majesty's sailors and soldiers, and consequently a special examination is instituted, and the refuse relegated to find out a living as best they can amid the

unsuspecting communities at home or abroad, while those qualified to practise amongst soldiers and sailors are preferred to posts of honour and emolument. Surely there is some gross anomaly in this not unworthy the attention of even a Royal Commission.

We make another grave charge against the occupants of our University chairs, and it is this, that no sooner is a man appointed to a professorship than he sets about devising how he can best accomplish the diversion of guineas from the students' into his own pockets—how, in short, he can best farm his academic position. The office of a professor is not unlike that of the great scientific drone, the parish clergyman. By means of slavish copying from well-known text-books, even in the English language, or an hereditary course of lectures, the oratorical quiver is straightway equipped. The statutory obligations of his office are thus met; but his cupidity for gold is far from satisfied, and he proceeds to institute what is emphatically termed, "A practical (very practical) class," or some other flimsy device, which, while attendance on it is not legally obligatory, he takes very good care virtually to make so by the part which he performs in the examination of the student for qualification in virtue of his office. That the teacher should have anything at all to do with the examination of the candidate is the grievance of which the extra mural lecturer complains, for reasons sufficiently obvious. It thus follows that while the curriculum of medical study *has not* been extended during the past twenty years, the subjects to be studied *have almost doubled*, so that if twenty years ago too much was compressed into a curriculum of four years' study, what must be the position of the student under the present *regime* with the same curriculum! A glimpse at the subjoined comparison will afford a startling idea of this:—

Curriculum of study at Glasgow, 1852.			Curriculum of study at Glasgow, 1881.		
	£	s. d.	£	s.	d.
Anatomy, 1 course	3	3	0	11	11
Practical anatomy, 1 course	1	11	6	5	5
Anatomical demonstrations, 1 course	2	2	0	5	5
Chemistry, 1 course	3	3	0	3	3
Practical chemistry	1	11	6	3	3
Chemical laboratory, optional					
Physiology, 1 course	3	3	0		
Surgery, 1 course	3	3	0		
Practice of physic, 1 course	3	3	0	21	0
Materia medica, 1 course	3	3	0	6	6
(Second course succeeding session, optional. Taken by those who could afford it to conciliate the professor, and facilitate the passing of degree examination).				3	3
Medical jurisprudence, 1 course	3	3	0	2	2
Midwifery, 1 course	3	3	0	5	5
Botany, 1 course	3	3	0		
Perpetual hospital ticket, including clinical lectures on surgery and medicine	12	12	0		
Total thirteen classes at a cost of	38	17	0		
				Total twenty-one classes at a cost of 76 18.	

Thus in a period of less than twenty years the number of classes compressed into the medical curriculum has increased from *thirteen to twenty-one!* and the expense has, as nearly as possible, doubled! when the time occupied in study remains exactly as it was. If twenty years ago the mental resources of the student were strained to the uttermost, does not the *auri sacra flammæ* intensify his present misfortunes? It will be seen, therefore, from the foregoing, that the position of a university professor is by no means an unremunerative one, and perfectly understood, that while they exhibited more business acumen than scholastic scruples, the two gentlemen who invested in chairs at the University of Glasgow, speculated not only wisely, but well. But the scandal of the supernumerary classes goes still further, not only are they excrescences on the old curriculum, but some of them are actually taught by unqualified men. We call, with righteous indignation, on the Royal Commission, to step in between the academic lust and the struggling student.

But our statements will doubtless be met with the antiquated rejoinder. "It is easy to find fault; what remedy do you propose?" We propose that the universities be relegated to their original position as merely teaching bodies; and we, their graduates, demand from the universities that which they profess to give us, "*potestatem damus plenissimam de re medica legendi, docendi, consultandi, scribendi, et disputandi in cathedram doctoralem ascendendi.*" We want a more substantial reward for our studies, our money, our time, and our graduation, than the mere jingle of a few Latin gerunds; we claim our original right of being permitted to teach, and of subjecting, in the interests of the public, the result of our teaching to an impartial and disinterested Board. "The most valuable additions made to a legislation have been enactments destructive of preceding legislation; and the best laws which have been passed, have been those by which some former laws have been repealed. . . . The whole scope and tendency of modern legislation is to restore things to that natural channel (a) from which the ignorance of preceding legislation has driven them." Let the universities by all means continue to teach, if they so desire, but why the privilege of teaching should be made a political reward, why professors of our universities should be protected by the State, and not be compelled to find their level in fair competition with other teachers equally willing to qualify candidates for the medical profession, it is really difficult to see. No reform will be acceptable to the medical profession except on these lines. We invite the attention of the Royal Commission to the glaring anomalies and abuses which we have indicated, and we challenge discussion, while we trust, as the result of the recent inquiry, to see one independent Board for each division of the kingdom established for the qualifying of medical practitioners, thus conceding justice to scientific aspirations, and reflecting certain benefit on the public.

THE state of the health of Prof. Pirogoff, according to the *Sarja*, published at Kiew, is in a very doubtful condition.

(a) Buckle. "History of Civilisation."

INTRODUCTORIES.

It may be noticed by our readers that we have this year, not printed in our columns any of the Introductory lectures delivered in any part of the United Kingdom. We have determined upon this course advisedly, having, though fully conscious that, by so doing, we withhold from our readers much really sterling and readable matter, arrived at the conclusion that the mental pabulum assimilable from inaugural school addresses bears an insignificant ratio to the flood of platitudes and goody-goody exhortation which students have to endure at this season of the year, and that it would be hopeless for us to undertake to select from the Introductories of the three kingdoms, the portions which might be either interesting or instructive to our readers.

It is a matter of course that, when leading or rising teachers in each school throughout the kingdom are entrusted with the duty of speaking publicly in behalf of his school, most of them will do their best, and—being chosen by their colleagues because of their proved capacity for the duty—will do it thoroughly well, and the resultant will be matter well thought out and well expressed. But the real truth is, that genius and labour are wasted in the production of an Introductory, because the oration must be unsuitable either to the immature student to whom it is addressed, or to the fully developed hearer or reader who has to sit it out or peruse it. Those of the speakers who devote their eloquence to "pathology" or "specialism," or some abstract question of the sort, have a subject worthy of their minds and of their rhetoric, but their oration is not an Introductory, nor is it a fitting preliminary to the studies of a bucolic medical student.

We believe, indeed, that we speak as truthfully the opinions of the students themselves as of their elders, when we say that they do not want and derive little profit from introductory lectures. These hyper-developed boys have the habits and all the acuteness of boyhood, and know well enough that the Introductory is a ceremonial maintained for the advertisement of the school and the lecturer, and that, very probably, their mentor has not, as a student, practised what he, as an Introductory lecturer, professes. Is it therefore, surprising that they fail to appreciate the solemnity of the occasion? or to respect the dignity of the great people who come to adorn the ceremonial? and that they are wont to give vent to their boyishness either in untimely and too audible criticisms on the proceedings, or in the explosion of minor fireworks such as children affect.

It is, indeed, hard to look solemn or feel serious under such provocation, but if the big-wigs of a college, university, or school feel uncomfortable when their dignity is not respected by "the boys"—we believe they have, generally speaking, wisdom enough to say nothing, feeling conscious that they have earned the infliction by assisting at a sham.

We do not, in the least, recognise the prevalent tomfoolery of medical students at introductory lectures as anything either clever or funny, or, in any way, worthy of toleration. It is, on the contrary, stupid, the natural emanation of youths who are themselves stupid, and at the time uneducated in professional etiquette, and who

mistake childish noise and unalloyed coarseness for fun. It is a time-honoured and popular formula to say that "old heads cannot be put on young shoulders," but we recognise no such excuse for the total absence of the feeling which ought to animate a gentleman manifested by those who think it fun to insult their teacher in his earnest effort, however mistaken it may be, to advise them for their good.

Viewed from all points, we are driven to the conclusion that introductory lectures are an unreasonable tax upon the solemnity of the grandes under whose auspices they are delivered, and upon the animal spirits of the boys to whom they are supposed to be addressed.

A school which means business can commence business as well without the preliminary posturing, and those schools which need such a start to stimulate their students to begin in earnest are not likely to gain strength thereby.

ANOTHER PROFESSIONAL SCANDAL.

UNFORTUNATELY for the profession of medicine, there are among its members always some, few though they may be, who by their actions bring unmerited disgrace on the whole body of their fellows. How to clear the ranks of such unworthy followers has long been a problem which has vexed reformers, and although a year or two perhaps elapses without the occurrence of any glaring exhibition of turpitude on the part of black sheep, still we are never left sufficiently long without some proof of their existence to banish the dread they are constantly reviving. This, it is, we very much fear, that is chiefly to blame for the inferior position held by medicine in the affections of the people; they cannot be blinded to the shortcomings of many of its professors, and with the hasty logic characteristic of imperfect education, they do not hesitate to brand the whole class as being more or less tinctured with the shortcomings of the few who are false to their principles.

We regret very much to record the fact that the past week has witnessed an exposure which is, at the best, a serious blow to the universal honesty of medical men; and although in this, as in every similar case, disgrace actually attaches only to the perpetrator of the evil, yet notwithstanding the brotherhood of the profession is so close—and rightly so—that all must suffer in some degree from the moral culpability of one. It will count nothing to offer extenuation in cases of this kind; indeed, the honest and proper course alone can be adopted in respect of it, and that must lead to complete and unconcealed condemnation of the proceedings into which the culprit has permitted himself to be drawn. Briefly, the facts are these: Mr. A. A. Sadgrove, a Licentiate of the Apothecaries' Hall, Dublin, wishing to obtain appointments which, by reason of his single qualification, he was ineligible to hold, descended first of all to misrepresentation, and subsequently to forgery, as is alleged, for the purpose of securing certain appointments which he could not otherwise obtain. At the outset he transgressed strict propriety and legal right as well, by describing himself on his door-plate as "Dr. Sadgrove, Physician and Surgeon," and this certainly with the knowledge that he had not obtained any qualification entitling him to do so.

Next he represented himself as a surgeon to the railway contractors, and on the strength of his statement received the appointment of surgeon to the navvies on the line. It however came to the ears of his employers that the Royal College of Physicians of London had already prosecuted Mr. Sadgrove, and that he had been fined for fraudulently representing himself as a licentiate of that corporation, this fact being proved in his own handwriting by his returns to Messrs. Churchill for the *Medical Directory*, whereby he unfortunately obtained admission to that work with L.R.O.P. Lond. after his name. Inquiries were thereupon instituted, and the man was constrained to yet other misstatements of facts in defence of his position. Suffice it to say that these included a declaration of his being a doubly qualified Licentiate of the Faculty of Physicians and Surgeons of Glasgow, in proof of which a diploma, asserted to have been forged, was exhibited. A letter to the Secretary of the Faculty, which miscarried, was followed by another epistle from the clergyman of the parish in which Mr. Sadgrove was practising; and this one being registered, reached its destination, eliciting in reply the information that the person described in it was not on the roll of licentiates of the Faculty. A letter in answer to the first which miscarried, and declaring in the name of the Secretary to the Faculty that Sadgrove was duly licensed, was thus shown to be a forgery, and on this, action was taken, and hence the public exposure of yet another misguided member of the medical profession.

That a gross fraud has been perpetrated on the public, in case all the facts recorded against the defendant in the trial alluded to are true, there can be no question; and that the profession have a right to demand the punishment of one who is likewise an offender against itself, must also be sufficiently clear. That the magistrates who committed Sadgrove for trial on a charge of forgery take a serious view of the case, is testified by the heavy bail demanded for his re-appearance, viz., himself in £300, and two sureties of £150 each. Nor can we wonder at this in the light thrown on the case at the first hearing. Defendant had attempted to possess himself of the license he is said to have forged by fair means, having presented himself for examination at Glasgow in January, 1880. His display of ignorance then, however, was too excessive to have any chance of success in the examination; and it is a serious fact against him that about this time a diploma form of the Faculty was missed—a most unusual occurrence. We cannot but assume that, pressed by the necessity of showing some evidence of his claim to be a surgeon, and without which he would not be permitted to retain the position he enjoyed improperly, the desperate expedient of forging the testimonial presented itself as a last resource; and influenced by the pressure surrounding him it may be, in a moment of weakness he succumbed to the irresistible temptation.

All this, however, is no excuse for the commission of crime. Indeed we are not sure that if proved to have been thus committed, it does not in some measure aggravate the offence; and in the punishment which follows, if conviction for this latter offence takes place, we may hope to find some indication of the certainty that ill-doing by members of the medical profession is as

surely visited with its just reward as in the case of any other wrong doer.

We unfeignedly regret that this has occurred. We could ill afford that it should do so, and the sting of the disgrace is keen and lasting. We can, however, point with satisfaction to the prompt measures being taken for the vindication of their own honour by the corporation primarily offended against, even as the London College of Physicians has already vindicated itself. Still we feel that such possibilities should be beyond us, or the need of them; and by-and-bye, when the profession is yet further improved, we feel sure it will be so.

Notes on Current Topics.

The Returns of Health Officers.

A VERY excellent suggestion was that which was made at an adjourned meeting of the Association of Medical Officers of Health at Manchester last week by Dr. Tatham, of Salford, that health officers should endeavour to arrive at some system of uniformity in their statistical records, so as to render their work of greater practical value. He said that, as they were just entering upon a new decade, and those of them who held the position of health officers would soon have to make preparations for the writing of their annual reports for 1881, the first year of the new decade, some endeavour should be made by those who had to administer the Public Health Act to arrive at this desirable consummation. The present unsatisfactory condition of our national vital statistics is undoubtedly due to the fact that, with respect at least to the large urban districts, the health officers are working solely with regard to local requirements, and entirely without reference to a national statistical system, and their reports are consequently well nigh worthless from the want of uniformity in the tabular forms employed. No statistical forms issued by local associations or individuals are likely to enjoy more than very local and partial adoption, and Dr. Tatham therefore suggested that the association should petition the President of the Local Government Board to instruct the medical department of the Board to prepare and issue officially a set of forms such as they would recommend for adoption by medical officers of health generally. The meeting concurring, a sub-committee was appointed to draw up a memorial in accordance therewith.

"Jerry" Fire Extinguishing Apparatus.

A CORRESPONDENCE is at present appearing in *The Fireman* on a subject which cannot fail to have especial interest for every householder, that, viz., of the quality of material supplied for the purpose of quelling fires. The excellence of workmanship and materials expended in the manufacture of fire-engines and hose is an important matter in its bearing on efficiency of the apparatus under pressure of a sudden emergency. The letters in *The Fireman* are of a disquieting nature in this connection. They assert that through shortsighted economy

and acceptance of the "lowest tender" by many departments and corporations advertising for supplies of this kind, a quantity of inferior hose and many useless engines are now being relied on to achieve the task of conquering fire should it unhappily occur and call for their employment. The pipes, of inferior leather, or of canvas deficient in resisting power, will, when brought into service, burst, and the engines be out of order, or found utterly unfit for the work required of them; and, as a consequence, possibly, lives will be sacrificed and hospitals crowded by the sufferers from a false parsimony. One glaring example is cited where a large building is fitted with hydrants and pipes of a pattern the correspondent describes as "obsolete," unreliable, and ill made. These charges are serious ones to bring against the present system of fortifying ourselves against the powerful element that is so justly dreaded; and in view of the very serious consequences that may ensue from the continuance of such a condition of things as is sketched, prompt and effectual measures should be taken for their very general improvement.

The Vital Statistics of the Country.

THE Registrar-General reports that during the three months ending September 30 last, there were born in the United Kingdom 278,170 children, giving a birth-rate of 31.6 per 1,000, the deaths in the same period numbering 143,518, or at the rate of 16.3 per 1,000. In England and Wales alone 215,586 births, and 109,956 deaths were registered, the death-rate thus being 16.7 or 2.9 below the average, per 1,000, of ten preceding quarters. The mortality from zymotic diseases, however, was considerable, and numbered 8,307 deaths attributed to diarrhoea, 3,535 to scarlet fever, 2,031 to whooping cough, 1,705 to fever, 1,341 to measles, 674 to small-pox, and 629 to diphtheria. The last named affection was slightly more prevalent than usual at the same period, and from it a death-rate of 0.10 as against 0.09 for preceding years is recorded. Small-pox showed a decided decrease as compared with the two previous quarters, when they were 730 and 1,213. Notwithstanding, the deaths from this complaint, 674, are in greater number than at any summer quarter since the great outbreak in 1871 and 1872. Of the total number of deaths, 461 took place in London, and 61 more in the Outer Ring, many others occurring in the counties immediately adjoining. Lancashire and Yorkshire contributed 34 and 15 respectively. 4,030 deaths, or 3.7 per cent. of the whole were uncertified, but these deaths show a further decline, nevertheless; 6,142, or 5.6 per cent. of deaths were certified by coroners in inquest cases.

At a meeting of the Indian Medical Service Defence Committee on Nov. 10, the following resolution was unanimously agreed to:—"That the report of a consulting actuary be obtained on the losses sustained by the members of the Indian Medical Service through changes made since 1858. That the actuary's fees be defrayed from the general fund, but, to provide for any possible deficiency, all officers who entered prior to 1860 be invited to guarantee the probable amount."

Ophthalmia Neonatorum.

In a recent number of the *Louisville Medical News* Dr. W. Cheatham devotes an article to describing the method of treatment adopted by him in cases of ophthalmia neonatorum. This consists essentially of careful application of astringents to the diseased eyes, these being first washed scrupulously clean. He emphatically condemns the use of the syringe, which he asserts is the cause of frequent accidents, even in the hands of skilled operators. Sponge, also, he decidedly objects to, as being on account of its texture and the difficulty of thoroughly cleaning it, a possible carrier of contagion, while at the same time it is actually inferior in point of efficiency to absorbent cotton, or soft rag. The remedies employed by Dr. Cheatham are, argent. nit. and tannic acid. He observes "Tannic acid does not serve in all cases, and when a substitute is required nitrate of silver (one to fifteen grains to the ounce of distilled water) will best serve the purpose. This is to be used in the same manner as the tannic acid, with the extra precaution that it must be washed out of the eye almost immediately with a solution of common salt (a teaspoonful to the half pint of water). This does away with all possibility of silver staining." The writer goes on to defend silver nitrate against the charges brought against it, and ridicules the dread of its use entertained by many practitioners, and adds that he has even employed it *forty grains to the ounce*. Oedema of the lids he treats by iced cloth applications, first smearing the delicate skin with grease to avoid excoriating it. Poultices he strongly denounces, and believes that infinite mischief has been caused by their use. Early treatment of the disease will always, he considers, save the eye.

Hospital Sunday Funds.

THE Hospital Sunday collection for Dublin took place last Sunday, and, as the weather was favourable, it is hoped that the yield of the collection will show an increase on that of last year. The annual collections in Birmingham were made on the 30th ult. for the twenty-third time. The returns show a considerable falling-off from those of recent years, the total received being barely £3,000, as compared with £4,886 last year, and £6,414 in the year 1878. Several returns have, it is true, still to be collected, but it is feared that these will not materially affect the total. On the other hand, the Hospital Sunday and Saturday collections in Liverpool this year produced £10,027, an increase of £306 over last year.

The Notification of Infectious Diseases.

In another column (Scotland) we have given a report of a case of neglect on the part of a medical man in Edinburgh to report a case of infectious disease, as required by the Edinburgh Police Act. With Dr. Bowie's views as to the difference between gastric and typhoid fever we have nothing to do; but the case raises some curious points, that do not appear to have been satisfactorily settled by the police court proceedings. It appears that the usual proceeding in Edinburgh is to send a police officer to confirm or not the diagnosis of the medical attendant, and that in the event of any probable

further inquiry, Dr. Littlejohn, the health officer, then goes to further confirm the policeman's diagnosis. This seems to have been the course adopted in Dr. Bowie's case, and to which he very naturally objects. If Dr. Littlejohn has so much to do that he cannot attend to all the cases reported, two or more medical inspectors should be appointed, whose duty it would be to make the necessary investigations. It certainly seems preposterous that the public should be subjected to the annoyance of these police visitations, and that the medical profession should have to submit to the diagnostic skill of an inspector of police. It appears also that Dr. Littlejohn never visited the supposed cases of fever till the day of the trial—a week or more after notice had been sent to him; and it was, therefore, entirely on the strength of the policeman's diagnosis that the prosecution against Dr. Bowie was commenced. This is a little too bad, and we cannot exonerate Dr. Littlejohn from the charge of a direct neglect of duty. It was his place to visit the case, and in omitting to do so he has dealt most unfairly with a brother practitioner. The profession will, moreover, obtain some little insight into the working of the Act, which certain would-be reformers are anxious to force upon the profession at large.

Coroner for County Monaghan.

ON the 3rd inst. an election for a coroner for the Northern Division of the County Monaghan was held in the Court House, Monaghan. There were four candidates, but at an early hour two resigned; and the contest, as was expected, lay between Dr. Stewart and Dr. William Woods, of Monaghan. The most intense excitement prevailed, and party spirit ran so high that upwards of two hundred police were employed in the town to keep order between the partisans of each side. At twelve o'clock both candidates were equal; but, in a few hours, the numbers showed in favour of Dr. Stewart, the Conservative candidate, who, when the poll closed at four o'clock, was 263 votes a-head of his opponent. Both gentlemen were chaired round the town by their supporters, and the town was not restored to its usual quietude until midnight. We wonder how long will the choice of a "judge of first instance" for the trial of cases of life and death be left in the hands of a mob of turbulent politicians, who—it may safely be said—would as soon elect an imbecile as anyone else, so long as he was of the right political or religious colour. What a glorious humbug our glorious constitution is in such matters!

Accident to Sir Edward R. Sinclair.

As Sir Edward R. Sinclair, Professor of Midwifery in the University of Dublin, was driving in Dublin on Tuesday week, his horses took fright and ran off. They dashed along at a terrific pace, until the carriage came against a lamp-post, and was over-thrown. The lamp-post was knocked down by the violence of the shock, and smashed into several pieces. The horses were caught by several carmen, who witnessed the occurrence, but, strange to say, neither the horses, the carriage, nor its distinguished occupant, received any injury.

The Election of a Councillor at the Irish College of Surgeons.

THE choice of a Member of Council, to succeed Dr. McClintock, took place on Saturday last, and brought together the largest assemblage of the Fellows which has for many years come together at a by-election in the College. Mr. Butcher was the candidate adopted to represent the views of those who have promoted the New Scheme of Education and Examination in the College. Mr. Kendal Franks offered himself also, his views being, we believe, also favourable to the reform. Dr. William Carte came forward, being avowedly hostile to the proposed change of system. Each candidate was actively supported by his own party, and their united efforts brought together 104 Fellows. The result of the poll was as follows:—Butcher, 64; Franks, 35; Carte, 5—a signal success for the party of reform.

Sponge Grafting on the Human Subject.

A CONTEMPORARY calls attention to an interesting new and important contribution to what we know of the *surgical* healing process, which comes from the pen of Dr. Hamilton, Pathologist to the Royal Infirmary, Edinburgh, and is published in the current number of the *Edinburgh Medical Journal*. It speaks of it as "Sponge Grafting;" and, although the experiments which led to its discovery were of a purely scientific character, it is not unlikely that they may prove to possess even greater interest from a clinical standpoint.

Dr. Hamilton, while engaged in the study of the "process of healing," was led to the belief that in the process of organisation of a blood-clot or a fibrinous exudation the effused material itself only plays a mechanical and passive part, and that their vascularisation is not owing to new formation of blood-vessels, but rather to a displacement and pushing inwards of the blood-vessels of surrounding tissues."

Rotundo Lying-in Hospital.

A STATED general meeting of the board of governors and guardians was held on Friday last, George Johnston, Esq., M.D., President of the College of Physicians, ex-master, in the chair. The routine business having been transacted, the president, vice-presidents, and the several officers were re-elected for the ensuing year. Proposed by Lombe Athill, Esq., M.D., Master, seconded by Robt. Wm. Arbutnot Holmes, Esq., J.P., and resolved—"That this board have heard, with great regret, of the death of Dr. Alfred H. M'Clintock, ex-master of this hospital, and desire to record their concern at this sad event, and their sense of the loss they have sustained by his removal from among them."

VON ARLT, the professor of ophthalmic surgery in the University of Vienna, would, on completing the seventieth year of his age in April, 1882, have retired in accordance with law, but has been requested by the Minister of Instruction to remain in office until the end of the academic year in 1883. He has consented to this, and has accordingly withdrawn his notice of resignation.

The Royal Society.

THE anniversary meeting of the Royal Society will be held, as usual, on St. Andrew's Day, the 30th inst. The following is the list of the Council and officers nominated for election:—President: William Spottiswoode, M.A., D.C.L., LL.D. Treasurer: John Evans, D.C.L., LL.D. Secretaries: Professor George Gabriel Stokes, M.A., D.C.L., LL.D.; Professor Michael Foster, M.A., M.D. Foreign Secretary: Professor Alexander William Williamson, Ph.D. Other members of the Council: Francis Maitland Balfour, M.A.; I. Lowthian Bell, F.C.S.; Sir Risdon Bennett, M.D.; Professor Thomas George Bonney, M.A.; Professor Heinrich Debus, Ph.D.; Alexander John Ellis, B.A.; Sir John Hawkshaw, M.I.C.E.; Thomas Archer Hirst, Ph.D.; William Huggins, D.C.L., LL.D.; Professor Thomas Henry Huxley, LL.D.; Professor Joseph Lister, M.D.; Professor Daniel Oliver, F.L.S.; Professor Henry Haffield Roscoe, B.A., LL.D.; W. Warrington Smyth, M.A.; Henry Tibbats Stainton, F.G.S.; Edward James Stone, M.A. Professor Huxley having retired from his office as one of the secretaries, Dr. Michael Foster has been named in his stead.

The Spread of Infection by Milk.

AT a recently adjourned discussion of a paper on the "Milk Supply," read at a meeting of the North-Western Association of Medical Officers of Health, by Dr. Vacher, of Birkenhead, it was resolved to memorialise the Local Government Board to issue a memorandum urging upon local associations the necessity of efficiently enforcing present regulations for the control of milk-sellers and the inspection of milk, and to grant to local associations additional powers to require all licensed milk-sellers to notify all cases of infectious disease appearing on their premises, with ability to close such premises till the removal of the infected animal or person and the disinfection of the premises, and to enable a local association to veto the sale of milk by vendors coming from without its boundary on evidence of infectious disease being on their premises. Many recent epidemics have been traced on unmistakable evidence to the milk supply, and more stringent powers in the hands of local sanitary authorities is therefore desirable, and should have the effect of limiting the spread of infection to the *locale* of discovery.

The London College of Surgeons and the Medical Acts Commission.

AT the ordinary meeting of the Council of the Royal College of Surgeons of England the report of the committee appointed to consider the question of the Medical Acts Commission was presented, and, after some discussion, adopted. The report practically recommended the establishment of a Conjoint Scheme. No person should, it stated, be registered as a legally qualified medical practitioner unless he shall have passed an examination in Medicine, Midwifery, and Surgery, such examination to be conducted by two or more of the existing corporations. The report also suggested that no University should be allowed to grant registrable licences in Medicine or Surgery apart from its degrees in Medicine.

The Cost of Sewage Farming.

It appears, from the annual statement of the Reading Sewage Farm, which has just been published, that there has been a total loss on the year's operations amounting to £146. The loss on the crops could not be put at a smaller sum than £1,500: but from the cattle had been received, for butter and milk, £2,743; cattle sold, £434; increase of valuation, after deducting expenses of purchase, &c., £535; sheep, paid for keep, £102; total, £3,815. It was stated, however, at the Council meeting, at which these figures were presented, that, looked at from a sanitary point of view, the farming operations had been a great success, and that Reading had never before been in such an excellent sanitary condition.

Pathological Society of Dublin.

THE annual general meeting of this Society, for the election of officers and transaction of other business, was held in the Anatomical Theatre of the School of Physic, Trinity College, Dublin, on the afternoon of Saturday, November 5. The chair was then taken, in the first instance, by the out-going President, Dr. Arthur Wynne Foot. After the signing of the minutes, Mr. Edward Hamilton proposed, and Dr. J. W. Moore seconded, a resolution to elect Mr. William Stokes as President of the Society for the ensuing session. The motion having been carried by acclamation, Dr. Foot vacated the chair, which, was then taken by Mr. Stokes. Mr. Hamilton moved, and Dr. Nixon seconded, a vote of thanks to Dr. Foot for his dignified conduct in the chair as President during the past year. Dr. Foot acknowledged the vote of thanks. Dr. J. W. Moore moved, and Dr. Nixon seconded, the following resolution, which was adopted in silence, viz.:— "That the members of the Pathological Society of Dublin desire to accord their sense of the great loss which the Society, as well as the cause of pathological science, have sustained by the lamented death of Dr. Thomas Hayden, one of the Vice-Presidents, and some time President, of the Society.

The following officers for the session 1881-82 were elected:—*President*: William Stokes, M.D. *Secretary and Treasurer*: Edward H. Bennett, M.D. *Secretary for Foreign Correspondence*: John William Moore, M.D. *Vice-Presidents*: John Thomas Banks, M.D.; Samuel Gordon, M.D.; Edward Hamilton, M.D.; George H. Kidd, M.D.; William Moore, M.D.; T. Jolliffe Tufnell, F.R.C.S.I. *Council*: John Kellock Barton, M.D.; Anthony H. Corley, M.D.; George F. Duffey, M.D.; John Magee Finny, M.D.; Arthur Wynne Foot, M.D.; Reuben Joshua Harvey, M.D.; James Little, M.D.; Thomas Evelyn Little, M.D.; Robert McDonnell, M.D.; Christopher J. Nixon, M.B.; John Mallet Purser, M.D.; John Benjamin Storey, M.D. *Committee of Reference of Morbid Growths*: Phineas S. Abraham, Reuben J. Harvey, Thomas E. Little, John Mallet Purser; with the President and Secretaries *ex-officio*. Resolutions were subsequently passed authorising the Council to take steps to effect an amalgamation of the medical societies of Dublin, and to arrange for the holding of special meetings of the Society from time to time for the reception of reports by the Committee of Reference.

Accident with Liquid Ammonia.

At the Belfast Sessions a case was heard in which a railway porter, named Murray sought to recover the sum of £50 damages from Mr. Hogg, druggist.

Eliza Murray, one of the complainants, deposed that she sent her daughter to buy one pennyworth of "head salts," as she was subjected to headaches. The girl returned with the bottle produced. It was put on the shelf and not used for a few days. Having a headache she lifted it to apply it, and had it in her hand for a few minutes when it exploded, the contents covering her face. Her eye was destroyed, and her mouth and throat burned, the skin of both having been torn off. It had been put on the mantelpiece previous to the time that she used it. When about to apply it she was sitting near the fire.

Dr. Gault deposed that on September 28th, he saw Mrs. Murray. Her eyes, mouth, and throat, were greatly swollen. The contents of the bottle produced was liquid ammonia. "Swelling" or "head" salts were usually prepared with carbonate of ammonia and a few drops of the liquid ammonia.

The defendant deposed that he sold the liquid ammonia to the plaintiff's child. The custom of the trade was to give either carbonate of ammonia or the liquid in a diluted form. That given to the plaintiff was diluted.

His worship granted a decree for £30 with two guineas for expenses.

A Medical Duellist.

DR. J. CROX, formerly Professor of Physiology at the St. Petersburg Medico-Chirurgical Academy, who at present is residing in Paris as the editor of the Bonapartist newspaper *Le Gaulois*, was, in consequence of some statement in that journal, challenged to fight a duel with the editor of another newspaper. He received, according to the *Wratsch*, a wound in the wrist.

Treatment of Rheumatic Fever by Salicin and the Salicylates.

THIS subject will be discussed at the Medical Society of London on December 5th. The debate will be opened by Dr. Hilton Fagge, who will furnish the experience of Guy's Hospital upon this matter.

THE Medical Acts Commission having decided, before closing their sittings, to receive evidence tendered on behalf of the Medical Alliance Association, Mr. Nelson Hardy, President of the Association was examined on Friday last.

THE inaugural address of the session 1881-82 at the Meath Hospital and county Dublin Infirmary, was delivered on Thursday, November 7th, in the theatre of the institution, by Dr. Arthur Wynne Foot, Physician to the Hospital. There was a very large audience of visitors and students.

THE banquet in honour of Professor Virchow is to be held at Berlin on the 19th inst., and promises to be highly brilliant and successful. The sum of 30,000 marks

originally proposed to be raised for the memorial appears likely to be greatly exceeded. This memorial, will consist of a marble bust of the Professor, and will be placed in the hall of the Pathological Institute on the above-mentioned day, in commemoration of his twenty-five years' labours as a teacher of medical science.

A TELEGRAM announces that the epidemic of cholera at Mecca is increasing. The mortality from this cause on the 3rd inst. amounted to 55, but on the two following days the number of fatal cases increased to 215 and 214. The pilgrims, adds the telegram, left Mecca on the 6th inst., and it was feared that the Egyptian troops at present stationed at Elwadj, amounting to 460, would be either unable or unwilling to prevent them from entering the latter town, the caravans numbering upwards of 5,000, and a spreading of the disease is feared.

It is announced that Professor Huxley has resigned the office of Secretary of the Royal Society (an appointment which he has held since 1872) in consequence of the pressure of other duties. It is reported that Dr. Michael Foster, Prælector of Physiology in the University of Cambridge, will probably succeed to the office.

CAN it be true that the number of deaths for which no certificate of their causes is given is greater in Edinburgh and Glasgow, than in all the other large towns of the United Kingdom? We have the official statement of the Registrar-General that, for the week ending Nov. 5th, there were 68 uncertified deaths in Edinburgh and Glasgow, whilst in all the other large towns of the kingdom put together but 67 such deaths were returned. This serious evasion of the law in the two northern cities should be inquired into.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population, were in—Wolverhampton 17, Portsmouth 17, Bristol 17, Edinburgh 18, Leeds 18, Sunderland 21, Sheffield 21, Brighton 21, Nottingham 21, Bradford 22, London 22, Leicester 22, Norwich 22, Manchester 22, Salford 22, Newcastle-on-Tyne 22, Plymouth 24, Birmingham 24, Glasgow 24, Oldham 26, Hull 27, Liverpool 28, and Dublin 30.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 23, Bombay 29, Madras 35, Paris 25, Geneva 20, Brussels 21, Amsterdam 22, Rotterdam 20, The Hague 24, Copenhagen 20, Stockholm 20, Christiania 16, St. Petersburg 36, Berlin 22, Hamburg 23, Dresden 20, Breslau 27, Munich 29, Vienna 26, Prague 26, Buda-Pesth 29, Naples 34, Turin 22, Venice 25, New York 26, Brooklyn 26, Philadelphia 20, and Baltimore 25. No returns were received from Lisbon, Rome, and Alexandria.

FROM diseases of the zymotic class in the large towns last week scarlet fever showed the largest proportional fatality especially in Hull, Nottingham, and Brighton; in Hull 36 more fatal cases of this disease were

recorded, making 393 that have occurred since the beginning of July. The 51 deaths from diphtheria included 19 in Glasgow, 13 in London, and 8 in Portsmouth. The highest death-rate from fever occurred in Brighton. Small-pox caused 15 more deaths in London and its outer ring of suburban districts, one in Liverpool, and one in Newcastle-upon-Tyne; no fatal case of this disease was registered in any other large town.

AMONG the passengers on board the ill-fated *Clae Macduff*, lost during the recent gales in the Channel, on the voyage from Liverpool to Bombay, was Surgeon Creed C. H. Smyth, of the Army Medical Department, who, having recently exchanged with a medical officer serving in India, in addition to being a passenger, appears also to have been in the position of surgeon to the ship for the projected voyage, so sadly terminated. His body has been recently picked up at Old Head, Kinsale, and buried in the neighbouring churchyard at Templetril. It is stated that a brother of his on board the same ship was also lost.

WE learn from a contemporary that the Senate of the University of London has recently passed a resolution, intended to overcome an abuse which has assumed rather large proportions. It is notorious that many undergraduates who have passed the first examinations for degrees have either directly assumed or allowed it to be implied that they are possessors of the full degree, and the Senate has therefore been compelled to alter the designation of the primary examinations by a resolution which runs as follows:—"That the First B.A., First B.Sc., First LL.B., First M.B. and First Mus.B. examinations be henceforth respectively denominated the intermediate examinations in Arts Science, Laws, Medicine, and Music.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

MESSERS. MOODY AND IRA D. SANKEY'S VISIT TO GLASGOW.—The inhabitants of Glasgow are informed through the press that the Directors of the United Evangelistic Association are arranging for a general invitation from ministers, office-bearers, and other Christian workers, being forwarded to Messrs. Moody and Sankey asking them to visit Glasgow. Mr. Moody, it is understood, has condescendingly signified his intention of meeting the ministers of the city and the directors of the United Evangelistic Association on an early day. We certainly regret the prospect of any such visit, believing as we do, that the form of excitement with which these peripatetic "Christian" Yankees are associated is both unholy and unhealthy. Some years ago they visited Glasgow. What was the result? Ladies of uncertain age, and weak-minded youths were afforded an unwholesome sympathetic excitation; the trade in American musical instruments was said to have been stimulated, and public morality was unquestionably debased. We trust the clergy of Glasgow will exhibit some better sense than participate in this contemplated "religious" pantomime. They will not raise themselves in public estimation if they, by their conduct, tacitly

confess, that the "American Evangelists" outgeneral them in their assaults upon evil, and Beelzebub in particular. If Messrs. Moody and Sankey will insist on coming here to beat the theological tom-tom, then in the sacred name of common sense, may their reward be the contempt of the majority of Scotchmen. Well may it be said of Sankey "*Ira furor brevis est.*" Surely, we are on the eve of a religious degeneration when "religious" stimulants have to be imported from America into the country of Gabriel Kettledrummle, Manse Headrigg, and John Balfour of Burley!

MATRICULATION AT THE UNIVERSITY OF EDINBURGH.—Over 2,500 students have already paid their matriculation fee for the coming session, the great bulk of them belong to the Medical Faculty.

THE CHAIR OF NATURAL HISTORY, UNIVERSITY OF EDINBURGH.—Another candidate for this chair has started up in the person of Mr. Patrick Geddes, who is returning to England with all speed to push his claims. The special claims of Mr. Geddes have not yet developed themselves, but must be held to be considerable, for that gentleman is leaving Naples, where he is engaged in a scientific investigation for the British Association.

EDINBURGH LITERARY INSTITUTE.—LECTURE BY DR. MACADAM.—The weekly lecture at the Literary Institute was delivered on the 9th inst. by Dr. Stevenson Macadam. The subject was "The Chemistry of Sanitation." It was, he said, now an admitted fact that air contaminated by overcrowding or by gaseous emanations from organic matters, such as evolved from common sewers, and that water polluted with sewage matters or sewage gases, as well as food tainted with putrefaction or disease, had an important bearing upon the health of individuals and of communities. In the elucidation of the conditions and laws which subsist between man and other animals and the outer world, comprehended under the general title of sanitation, chemistry had played a foremost part, in explaining the atmospheric and other causes which led to the sustenance and spread of noxious germs and organisms. The lecture, which was illustrated throughout by many diagrams and experiments, was listened to with great attention.

"COMBE-TRUST" LECTURE.—The fifth of this series of lectures was delivered in the City Hall, Glasgow, on the 7th inst. by Dr. MacCall Anderson who chose for his subject "Small-pox and Vaccination." Mr. I. Campbell White presided. In the course of his remarks Dr. Anderson stated that there was at present a tendency to despise the need for a remedy, owing to the absence of small-pox. Against the practice of vaccination certain objections had been raised which merited a passing notice. It had been urged that to make vaccination compulsory was an unwarrantable interference with the liberty of the subject; but it must be remembered that in many other instances, where danger was likely to accrue to the public the law interfered. It had been said that there was a risk of the animal virus introducing poison into the blood, though this had been denied by distinguished authorities. His own experience led him to admit that such an occurrence was possible, but only when vaccination was performed by unskilful persons, or when reasonable precautions were neglected. He had no hesitation in saying that if he were compelled to have his blood poisoned by vaccination, or run the gauntlet of small-pox, he would unhesitatingly select the former.

GLASGOW OPHTHALMIC INSTITUTION.—The opening of the new extension of the Glasgow Ophthalmic Institution took place on the 7th inst. There was a numerous and influential

attendance. Mr. James White of Overtoun presided. In the course of his address the chairman stated that while in 1870-71, when the institution was first started, the number of patients was 119 in-door, and 1,257 out-door, last year the number was 373 in-door, and 3,227 out-door. He lavished eulogiums on Dr. Wolfe, and indulged the general apothecosis which is characteristic of the annual meeting of this institution.

ABERDEEN RECTORIAL ELECTION.—The election of a Lord Rector for Aberdeen University took place last Saturday, and resulted in Dr. Alexander Bain, the late Professor of Logic in the University, being returned by a large majority. The state of the poll was as follows:—Dr. Bain, 444; Sir James Paget, 238. About a year ago Dr. Bain was defeated for the post of assessor by the clerical party in the University; his election will, for the next three years at least, give him two instead of one vote in the councils of the University. His failure was attributed to his supposed materialistic views, and the probability is that he would not now be Lord Rector had he not then failed. Dr. Bain is to be congratulated on his success.

NEGLECTING TO REPORT INFECTIOUS DISEASES UNDER EDINBURGH POLICE ACT.—At the Edinburgh Police Court last week, before Sheriff Hamilton, John Bowie, medical practitioner, Edinburgh, was charged with contravening the 208th section of the Municipal and Police Act of 1879, in so far as he failed to report to the medical officer of health that there were cases of infectious diseases under his care. Mr. Bowie conducted his own case. Dr. Littlejohn, medical officer of health for the city, said that on the 19th of last month he received a letter, drawing his attention to cases of typhoid fever, and that he sent Inspector Kay to the place, and on receiving his report, visited the house himself, and then wrote to Dr. Bowie, asking why he had not, as required by the Act, reported the cases to him. Dr. Bowie replied to the effect that he was not aware he was required to do so. In answer to the accused, Dr. Littlejohn said that if it was necessary he would describe the symptoms of typhoid fever, but it might take half an hour to lecture on the subject. The Sheriff inquired if there was any kind of fever that was not infectious, to which Dr. Littlejohn replied in the negative. Dr. Bowie (to Dr. Littlejohn)—Is rheumatic or intermitting fever infectious? Dr. Littlejohn—I don't think so. Dr. Bowie—Then why do you say there are no kinds of fever but what are infectious? Dr. Littlejohn—Oh, I think his Lordship understands me. The accused proposed to produce printed authorities on the symptoms of typhoid fever, but these, the Sheriff said, could not be accepted as evidence. Dr. Bowie could put the authors into the witness-box if he chose. At the close of the evidence, Dr. Bowie submitted that it had not been proved that, according to the symptoms of his patients, they were afflicted with typhoid fever. The Sheriff said he could not quite go into the technical question of symptoms. The object of the Act was to prevent the spread of infectious diseases; consequently he thought the Act should be read broadly and not narrowly. Therefore he was inclined, in the absence of any evidence for the defence, to find the charge proven; but as it was the first case of the kind, the penalty would be nominal—one of 10s., or three days' imprisonment. Dr. Bowie—My Lord, can I appeal in this case? Mr. Linton (the prosecutor)—Oh, yes. The fine was paid.

THE CHAIR OF NATURAL HISTORY IN EDINBURGH.—We learn on good authority that Professor Sir Wyville Thompson has not yet tendered his resignation of his Chair, and that reports of his resignation are at least for the present premature.

ST. ANDREW'S UNIVERSITY.—Sir Theodore Martin, K.C.B., has intimated his intention of delivering his inaugural address as Lord Rector of the University of St. Andrew's on Monday, the 21st inst. He is to be accompanied by Lady Martin, and both will be the guests of Principal Tulloch.

Literary Notes and Gossip.

THE Committee of Selection, at the recent meeting of the American Medical Association, have selected as the subject for the prize to be awarded in 1883 the following question:—"What are the special modes of action or therapeutical effects on the human system of water, quina, and salicylic acid when used as antipyretics in the treatment of disease?" The essays must be founded on original experimental and clinical observations, and must be sent in to the Committee of Award on or before the first day of January, 1883.

If there be not a royal road to learning, teachers and authors endeavour to remove all difficulties in the way of traversing the old paths. In this direction Mr. Joseph Ince, F.C.S., F.L.S., has removed a great stumbling block and smoothed the road for candidates for examination in Pharmacy, by a Latin Grammar, containing the fullest explanation of the grammatical construction and distinctive character of the language, and complete directions for the reading of Latin prescriptions. To compounders this will be of considerable value, as physicians are not always understandable.

MOST of the medical, scientific, and literary societies are now in full session, the one or two remaining will commence during the next few days. The first meeting of the One Hundred and Twenty-Eighth Session of the Society of Arts will be held this (Wednesday) evening, when the opening address will be delivered by Sir Frederick J. Bramwell, F.R.S., chairman of council. Previous to Christmas there will be four ordinary meetings in addition to the opening meeting. The Association of Surgeons practising Dental Surgery, also holds its inaugural meeting this evening. The Statistical Society commenced last evening (Tuesday), with an address by Prof. Caird, F.R.S.

WE understand that the "Transactions of the International Medical Congress, 1881," will be published at the beginning of December. The complete work will consist of 3 vols. royal 8vo, and will be supplied to non-members at the price of 30s.; but we are a little uncertain whether members will be entitled to them by virtue of their membership. It would hardly be reasonable to expect this, considering the value members have already had for their guineas, and the enormous cost of producing the abstracts already supplied, and the Transactions about to be published; but the question has frequently been put to us, and some official pronouncement on the subject is desirable.

SOME few months ago we announced that an "International Encyclopædia of Surgery," by authors of various nations, edited by John Ashhurst, Jr., M.D., Professor of Clinical Surgery in the University of Pennsylvania, had been undertaken by the publishers of "Ziemssen's Cyclopædia of Medicine," the first volume of which would appear in October. The promise has not yet been fulfilled, and at present no sign of the coming king appears on the literary horizon. Perhaps, like Baal, the editor is "asleep, and must be awakened, or he is on a journey," and has not yet returned from the International Medical Congress. Whatever be the cause of delay, our anxiety increases in accordance with its duration, the surgery of volumes sometimes leading to amputation.

A COMMENDABLE attempt is being made to popularise science by the issue during the last few days of a new weekly periodical entitled, "Knowledge; an Illustrated Magazine of Science, plainly worded, exactly described." The editor is Mr. R. A. Proctor, of astronomical fame, whose last literary venture, "The Stars of the Earth," is having a very large success. The initiatory number of the new journal promises well, but the difficulty scientific writers have to contend with is the bringing of their advanced ideas to the level of ordinary readers. If Mr. Proctor and his friends

succeed in this, "Knowledge" will become an institution, but not otherwise. The journal is well got up, its first number is a mine of wealth, and the price, twopence weekly, should place it within the reach of all who are "thirsting after Knowledge."

THE literature of otology increases rapidly, though British authors do not contribute much. It is in Germany and Austria that most of the otological work of the present day is done. The publication of the first volume of Prof. Politzer's text book (the second volume of which will, we hope, soon appear), was followed by that of Prof. Urbartschitsch, then in America by the practical volume of Dr. A. H. Buck, and now Prof. A. Hartmann, of Berlin, has brought out a volume on the Diseases of the Ear. Some of these German works will, we understand, be translated for the benefit of the profession in this country, that of Prof. Politzer being already in an advanced state by Dr. Patterson Cassells. Prof. Urbartschitsch's has already appeared in French, and we should like to see it in English, though still better should we welcome a comprehensive text-book from a British otologist.

THE first number of a new claimant for the favour of ophthalmic Specialists, has just been issued by Messrs. Churchill, under the editorship of Dr. Karl Grossman, of Liverpool, and Mr. Priestly Smith, of Birmingham. It is named "The Ophthalmic Review" and it will appear monthly at the cost of 1s. We can welcome the advent of a new representative of special journalism, although we are obliged to confess that—with our experience of newspapers—we hardly hope for a very prolonged or lucrative career for a periodical, which caters for so limited a constituency as the ophthalmologists. The new journal leads off with an excellent article by the prolific and ever original Mr. Hutchinson, on "Retinitis Pigmentosa" and allied affections, as illustrating the laws of heredity, which, being to "be continued in our next," will ensure a sale for the first two numbers of the journal, at least. The rest of its pages are filled with well selected excerpts, which, though not original matter, are none the less instructive. We shall look with interest for future issues of the *Ophthalmic Review*.

UNDER the pretentious title of "The British Imperial Atlas," Messrs. Letts, Son, and Co. have just bound up series I. and II. of their "Popular" into a most useful collection of 76 maps, with consulting index of 23,000 names, which they offer to the public at a price never before attempted in this country, viz., 21s., on paper, in handsome cloth covers, gilt edges, bevelled boards, or 47s. 6d. for their indestructible edition (a very novel and useful feature in atlases). There are beautiful Geological Maps of England and Wales, and the Environs of Dublin, Edinburgh, and London. The populations are delineated by colour from 3,000 to over 100,000; every important lighthouse, every lifeboat station is clearly marked; the old and interesting round towers of Ireland, the cathedrals of the two islands, and the depths of the ocean are all shown by colour. In the Indian maps we find the very latest results of the most recent surveys and explorations in the North-west, and Afghanistan; whilst the historical alterations of boundaries by the treaty of Berlin of 1878, and the Greco-Turkish boundary conference of 1880, are all duly recorded.

WE regret to learn that, notwithstanding the unremitting efforts on behalf of the "Index Medicus," the degree of support which that very useful publication has received from the profession, by way of *bona fide* subscriptions, has not been sufficient to meet the expense of issue during the current year, and the publisher has reluctantly been forced to call upon those who so promptly volunteered to see him safely through this year's issue, for the amounts severally guaranteed by them. The continuation of the "Index" for another year must depend upon the profession, and as it is necessary, in justice to the editors and publisher that an early decision should be reached, every subscriber is requested to respond to the following questions at the earliest moment possible:—1. Will you renew your subscription to the "Index Medicus" for 1882 at 6 dols.? 2. In what manner can you help to secure the "Index Medicus" against actual loss during 1882? The decision whether or not the "Index Medicus" is to continue, will depend upon the responses received to these two questions. To cover the deficit, £250 will have to be guaranteed by Societies or individuals, before the publisher will undertake

the publication for another year. From private information, we believe we are correct in stating that out of the entire subscription list, only about three in a hundred are from the United Kingdom, the rest being in the United States. Of course it will be argued that it is an American publication; true, but it is also an International one, and on this account, and on that of its value to authors, we shall be glad to learn that it is more liberally supported.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, Oct. 5th:—"A Treatise on Chemistry." By Professors Roscoe and Scholesmmer, F.R.S., Vol III. "A Practical Treatise on Impotence, Sterility, &c." By S. W. Gross, M.D. "A Treatise on Medical Electricity." By R. Bartholow, M.D. "An Essay on Suicide." By Hy. Morrell, M.D. "Dramatic Singing Physiologically Estimated." By W. Hayle Walahe, M.D. "University College Hospital Surgical Reports", 1880. "Davos Platz as a Winter Station." By J. E. Muddock. "Koumiss." By G. L. Carrick, M.D. "Manual of Diseases of Children." By Ed. Ellis, M.D. (4th Edit.) "Lectures on the Physical Examination of the Mouth and Throat." By G. V. Poore, M.D. "An Index of Surgery." By C. B. Keetley, F.R.C.S. "On Cholera." By Octavius Sturges, M.D. "On Diseases of Women." By Arthur W. Edis, M.D. "Table of the Average Weights of the Human Body and Brain." "The Latin Grammar of Pharmacy." By Joseph Ince, F.C.S.

PAMPHLETS.—The following have been received since the publication of our last list:—"A Propos du Railway Transsaharien, Reflexions Hygiéniques et Médicales." Par C. J. Masse, M.D. "Vaccination." By Peter A. Taylor, M.P. "Convulsions due to Depressions of Spinal Inhibitory Centres." By E. T. Reichert, M.D. "Ethylene Bichloride as an Anesthetic Agent." By the same author. "Report to the Local Government Board of the Outbreaks of Small-pox in Maidstone." "Chemical Notes and Equations." By R. Milne Murray, M.D. "Hunter and the Stag." A reply to Professor Owen, from the Scientific point of View. "The Unity of Poison." By G. de Gorrequer Griffith, M.D. "Cases of Hepatotomy." By Lawson Tait, F.R.C.S. "Life Assurance." By F. A. C. Hare. "Cirrosi Ipertrofica del Figato." Dell Dr. G. B. Ughetti. "The Toxicology of Cardiac Depressants." By E. T. Reichert, M.D. "Liberty and Authority in the Study of Medicine." By J. W. Haward, F.R.C.S. "Diphtheria." By Robert Bell, M.D.

Novelties.

A NOVEL MEDICAL CAB.

THAT existing conveyances do not supply the need of practitioners, especially in districts which have to be traversed in all weathers and under varying circumstances, is evidenced by the number of letters we receive from time to time asking advice on the subject. During the present month an Industrial exhibition has been held in London at the Alexandra

Pfäce, and amongst the various exhibits were cabs and carriages of almost every conceivable variety. Of these one struck us as particularly useful to medical men who do not themselves drive, viz., "The Empress Patent Hansom," this is the invention of Lieutenant Dalzell, and is manufactured by a Mr. Thomas Eardley, of 13 Henry Street, Hampstead Road, London, which obtained the medal of the exhibition. The improvements in this over existing hansoms consist both in the means of ventilation, convenience, space, and noiselessness. The old falling windows are entirely superseded by others sliding from the side, which can be worked either by the passenger or the driver, thereby giving increased space in the front, together with better ventilation and view, and effectually overcoming the inconvenience arising from the old plan of the windows falling suddenly upon the hat or head, and the necessity of having to call the driver whenever occasion arose for it to be closed or opened. It is moreover easier of ingress and egress—a consideration when many calls have to be made—is remarkably comfortable, has a speaking tube inside for communication with the driver, and is of elegant exterior as the foregoing woodcut shows.

DR. WARD COUSIN'S BED-CLOTHES ELEVATOR AND EXTENSION APPARATUS.

The elevator can be fixed to any bedstead by a clamp, and at the same time it can be applied either at the ends or the sides of the bed. It serves also many other useful purposes. It will suspend a weight or icebag in any position over the body, or it can be converted into a very convenient stand for a vessel, as in the application of an evaporating lotion.

For the purposes of extension the bed-clothes elevator is fitted with a pulley, which is suspended by means of a sliding bracket from the back of the instrument, and is thus capable of adjustment at any convenient height. A sliding collar with a clamp working on a hinge is also supplied for the purpose of fixing securely the upright to the bedstead in those cases in which counter-extension is obtained by raising the foot of the bed. The apparatus is fitted with two counter-extension blocks, each giving three elevations, movable weights, and in fact everything necessary for the immediate use of surgeons practising in the country, or of medical officers going abroad.

SERIOUS CHARGE AGAINST A SUNDERLAND PRACTITIONER.

ALLEGED CONSPIRACY TO DEFRAUD.—Last week at the Sunderland Police Court, Dr. Abrath, medical officer to the Hospital for Foreign Seamen, appeared on a charge of conspiring to defraud, in conjunction with a man named M' Mann. Mr. J. L. Walton, barrister, instructed by Mr. Dix, solicitor, Gateshead, appeared for the North-Eastern Railway Com-

pany. Mr. Barker, the deputy clerk to the Bench, read the warrant, which stated that information was laid on November 7 against M'Mann and Gustave Adolphe Abrath to the effect that between the months of August and November, 1880, in Bishopwearmouth, they did unlawfully conspire together by divers false pretences to fraudulently obtain, and in pursuance thereof one or other did obtain, a large sum of money from the North-Eastern Railway Company. Mr. Walton in opening the case for the prosecution, said on September 10, 1880, there was a slight collision between a passenger and a luggage train, the jolt was of the slightest nature, but it was sufficient to throw the defendant M'Mann who was seated in a third-class carriage, against a partition immediately in front of him. He did not seem to be much hurt, and made no serious complaint. He got out at Durham station and changed into the Sunderland train without any assistance. On reaching Sunderland he walked to his home without assistance in the same way, and ultimately he put himself under the charge of Dr. Abrath, who had the medical custody of the defendant M'Mann from September to the following July. In the month of October a claim was made by M'Mann for very heavy compensation. That claim was compromised, and the sum of £700 was paid over to him or to his solicitor, Mr. Skinner, and the sum of £300 was agreed upon for costs. That compensation was paid in consequence of the representations of the man's condition, which were entirely false. It is charged that this man simulated subjective symptoms, and created with the co-operation of his medical attendant certain subjective symptoms. These subjective symptoms, which he was said to feel, were entirely fictitious, and the condition of the man was produced by artificial means at the instigation and under the agency of his medical attendant. If that were proved from evidence there could be no doubt that the conspiracy was actually cemented between these two men by the creation of these symptoms in order to defraud the company. The companies were exceptionally liable to frauds of this kind, and they had felt this to be a very important case. The solicitors then applied for a remand of the case for a week, which was granted, and both defendants were admitted to bail.

NOTICES TO CORRESPONDENTS.

DR. N. K.—Thanks for communication, but if we mistake not, all the main facts and arguments have already appeared in our columns; we have not, therefore, space to repeat them.

DR. E. T.—Sorry we cannot publish your lines on President Garfield. Firstly, because it is not up to the commonest standard of rhyming; secondly, because we disagree with the inference that—

"Doubtless recovery had been complete,
If changing to sea-air was not too late."

Thirdly, although the subject was an honourable and successful soldier and politician, we can hardly admit that—

"The greatest of humanity has passed away."

CAPILLARY-TUBES.—"Novice" asks where he can get capillary-tubes for vaccine-lymph, and also if it would be safe to use the tubes a second time?

[Capillary-tubes for collecting vaccine-lymph can be purchased from any surgical instrument makers or drug contractors at one shilling a hundred; they are supplied gratuitously to all dispensary medical officers under order of the Local Government Board, and when required should be applied for in the requisition for medicines, &c. Capillary-tubes will be found in the new forms of requisition for medicines, &c.—Ed.]

MR. NIXON.—Some boards require a certificate of having passed an examination in Public Health from one of the universities, special examinations on this subject having recently been fixed by most of these bodies. Many local authorities do not require this, but you must be prepared to show a practical acquaintance with health matters generally when making application for an appointment. On reference to our "Student's Number" you will find advertisements relating to both public and private instruction in public health.

C. H. G.—We shall be happy to publish the results of your investigations with your name attached; the views are decidedly heretical.

M.R.C.S. (Sunderland).—We cannot comment upon the case *sub judice*, but must content ourselves with a short record of facts as they occurred in connection with the case in the police-court; this you will find in another column.

MR. HOOPER.—Thanks for the local newspaper containing reports; you will find the case referred to in our leader columns.

DR. J. J. RIDGE.—The notice of meeting appeared in our last issue.

M.D.—The advertisement of "Mr. Hentsch, M.B.C.S. Eng." in the local papers is most objectionable, but, unfortunately, the practice has become so common of late that to take every case up would

almost fill our columns. We regret that any member of the profession should condescend to advertise "consultations and advice gratis to the working classes" side by side in the newspapers with his letterman and greengrocer.

DR. D.—The subject has been so thoroughly threshed out that we fail to see what can be said that has not already appeared in our columns. Perhaps later on something may arise on which a renewed discussion may be desirable.

MR. HOSKINS.—'Tis most unusual to give the names or addresses of writers of unsigned articles. Any communication addressed to the Editor will receive due attention, and probably reach the gentleman concerned.

AN OLD SUBSCRIBER.—We are a little uncertain as to the date, but will make inquiries and communicate with you by note.

QUINQUININE.—A correspondent asks "how is it that two firms, Messrs. Mackey & Co. and Mr. Sellers, advertise in your columns the quinine substitute 'quinquinine,' each that that only is genuine bearing their or his name, thereby assuming that the other is a spurious preparation. I am a little curious on the subject, as I have had good results from its use for some few years, and want to know if it is a 'trade mark' article, how a second firm can make it, as I want to be sure of getting the genuine preparation in future?"

[The reply to this question should set our correspondent's mind at rest on the score of genuineness. Messrs. Mackey & Sellers were, we believe, formerly partners as manufacturing chemists; "Quinquinine" was one of their registered articles, and was advertised as Mackey & Seller's Quinquinine. Last year the firm dissolved partnership, and as they now carry on business separately, each in its right, we presume, of manufacturing and selling the article in which the name of the firm jointly was associated. Either, therefore, is genuine, and the reference to each other in the advertisement is unnecessary and misleading.—Ed.]

AN INSPECTOR.—If you go in for the certificate of the Sanitary Institute of Great Britain you must be prepared for examination in the Acts relating to the Public Health and the Sale of Food and Drug Act, and to show some practical knowledge of ventilation, disinfection in cases of contagious diseases, &c., and of the nature and fixing of soil-pipes, sink-pipes, and overflow-pipes of a dwelling so as to prevent any danger to the inmates.

THE FULLERIAN PROFESSORSHIP OF PHYSIOLOGY of the Royal Institution of Great Britain is vacant. Candidates are requested to apply before 24th November.

THE SOCIETIES.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.—The (Wednesday) evening, at 7.45 o'clock, Council.—8.30, Casual Communications.

HARVEIAN SOCIETY OF LONDON.—Thursday, Nov. 17th, at 8.30 p.m. Dr. G. C. Henderson, "On a Case of Small-pox followed by Amy." Dr. Cavafy, "A Case of Sciatic Nerve-stretching in Locomotor Ataxia."

Vacancies.

Belgrave Hospital for Children, London, S.W.—House Surgeon, Salary £30, with board. Applications to the Hon. Sec. by Nov. 23.

Charing Cross Hospital.—Assistant Physician on the Staff. Applications to the Secretary on or before Dec. 3.

Gateshead Dispensary.—Resident Surgeon. Salary, £210. Applications to the Hon. Sec., 2 Side, Newcastle-on-Tyne, by Nov. 23.

Liverpool Dispensary.—Assistant House Surgeon. Salary commencing at £108. Must be unmarried. Applications to the secretary by Nov. 22.

North Dublin Union.—Medical Officer. Salary, £150 per annum.

Election, Nov. 30. (See Advt.)

Ruberry Hill Asylum, Bromsgrove.—Assistant Medical Officer. Salary £100, with board. Immediate applications to the Medical Superintendent.

Births.

DUDLEY.—Nov. 3, at Durrrow, Queen's County, the wife of Henry J. Dudley, M.D., of a son.

KING.—Nov. 12, at Ambleside, Westmoreland, the wife of W. Max King, M.B.C.S., of twin girls.

Marriages.

ATKEY—ANDERSON.—Nov. 8, at All Saints' Church, Chichester, W. J. Atkey, L.R.C.P. Lond., &c. of Chichester, to Mary Catherine, daughter of J. Anderson, Esq., of Stockbridge, Chichester.

BLYTH—FINDLATER.—Nov. 12, at the Presbyterian Church, Kipp town, John Blyth, M.D., of Dublin, to Jane, widow of A. S. Findlater, of Kingstown.

KILNER—GOFF.—Nov. 9, at Horeton Church, co. Wexford, C. R. Kilner, M.B., youngest son of J. Kilner, F.R.C.S., of Bury St. Edmund, to Lucy, youngest daughter of S. Davis Goff, J.P., of Bury House, co. Wexford.

Deaths.

ERSKINE.—Nov. 7, at Sandys Place, Newry, Archibald Erskine, M.D.

FIGGINS.—Nov. 4, at Crabtree, Sheffield, Henry Figgins, F.R.C.S., 66 of Birmingham, aged 68.

MARSDEN.—Nov. 11, at Norwood, Elizabeth, widow of Wm. Marsden, M.D., of Lincoln's Inn Fields, London, aged 75.

MCCARROGHER.—Nov. 5, at Chichester, Joseph McCarrogher, M.D.M., aged 93.

M'EVoy.—Nov. 10, at his residence, Balbriggan, co. Dublin, after a long and painful illness, Francis M'Evoy, M.D., in his 66th year.

of which retain their vitality amid such extreme temperatures, that the wonder is the world is not depopulated by them; but the physico-chemical theory places zymotic virus under the same atmospheric influences as other organic matter, whereby it is soon reduced to elementary forms. Hence the dead are not contagious, and epidemics cease." Dr. Richardson also considers, and I agree with him, "that zymotic poison may, under extreme malhygienic states, arise *de novo* in the secretions, from which effects follow precisely, as though it had been introduced into the body, and attributes the immunity from, and tendency to, infectious diseases at various ages, to a constitutional or physiological peculiarity of secretion; and the non-recurrence of the same disease, in the same person, to the elimination of particles in a secretion susceptible of zymosis." Moreover, he says, "I protest that the attempt to connect our knowledge of the minute organisms with the phenomena of the various communicable diseases, so as to suggest, or, as some do, to assert that the diseases in question arise from germs, and that the person affected with a contagious disease has been fertilised like a piece of ploughed land, or virgin soil, with a crop of germs, and in turn he is the soil in which another crop is being produced, by the independant increasing or multiplying of the germs in him. I protest, I say, that this hypothesis is the wildest, the most innocent, the most distant from the phenomena it attempts to explain, that ever entered the mind of man to conceive. What most astounds me is that men who are conversant with the practice of physic, who are treating diseases of a communicable kind every day, should for a moment connect such a hypothesis with the phenomena they have under their observation. Does any one of them believe that hydrophobia is from a germ, that syphilis is from a germ, or other diseases I need not specify?"

It is favourable to the physico-chemical theory that certain epidemics as sweating sickness, black death, and plague, have long disappeared from this country. I may mention that in one night in London the plague caused 4,000 deaths, and in one week 12,000. If these pestilences arise from living germs, whither have the germs gone? If relapsing fever, of which we had an epidemic in Glasgow about ten years ago, depends on germs or on the organisms spirilla, alleged to be found in the blood of relapsing fever patients, whence did the germs or spirilla of that epidemic come, and whither have they fled? I think it far more likely that these affections did not arise from living germs at all, but from putrid poisons generated both in and out of the body, from abounding decomposing organic matter, filthy habits, ignorant and systematic violation of the laws of health, and that they were propagated in accordance with the physico-chemical theory. Further, as their extinction is unquestionably due to increased knowledge and improved sanitary conditions, hence by the same means we may reasonably expect, in course of time, to exterminate the other members of the zymotica; and moreover, I believe that a return to the insanitary conditions under which our forefathers lived, would again conjure to life the fearful epidemics referred to. But whether zymotic poison be living germ or putrid speck, if it be at all tangible, what does the microscope or test-tube say about it? As already indicated this problem is not only one of the most complex that the mind can grapple with. Although, of late years, diligent search has been, and is being made by the highest qualified persons, and with the best apparatus procurable, for the different human zymotic poisons, yet in reality only one has been found, viz. that of small-pox. This virus is easily obtained pure from a small-pox patient during the vesicular stage of the eruption. Like vaccine lymph it is fluid, translucent, odourless, alkaline, and albuminous, hence coagulable by heat and acids. Under the microscope both are found to contain numerous black, roundish, motionless particles, about 1-20,000th of an inch in diameter. M. Chauveau, a distinguished French veterinary path-

ologist first, and Dr. Burdon Sanderson, of London, latterly, succeeded by an ingenious method in separating the particles from the fluid parts. After this they found that a child might be vaccinated or inoculated with the fluid without effect, while the minutest portion that can be separated of the solid parts causes all the phenomena of cow pox or small-pox. Now the question comes to this—are these black virulent specks motionless organisms, or simply putrid particles? This is yet unanswered, although the germ theorists consider them organisms and call them micrococci. So also is the query—are the specific viruses of scarlatina, typhoid fever, &c., &c., of the same form? Any answer to the latter question can only be a mere surmise founded on inference, for the simple reason that these viruses have never been seen.

Some distinguished pathologists in France and Germany as well as in Britain seem to have their minds made up that all communicable diseases and many of an inflammatory nature, of man and the lower animals, are caused by minute living organisms. Now it was formerly held that the bacteria of putrefying fluids were the probable cause of such affections by their gaining access to the blood. But when it was shown that these were ever present in non-zymotic subjects—in the tartar of the teeth, in effete epithelial cells, in alkaline urine, &c., that they were swallowed by the million with impunity in stale cheese, high game, tainted flesh, and "turned milk," and that they were absent from the blood both of healthy and diseased persons, it was then conceded that the alleged virulence of organisms found in such fluids, and in alleged infectious pathological products, depend on the chemical condition of their environment; or in other words, that harmless organisms were metamorphosed into virulent ones, by an increased morbid change in their life conditions. Now this clearly implies, though partly denied by some germ theorists, that the essential virus is the material in which the organisms live, and not the organisms themselves; and these were next held if not constituting specific virus, to be at least carriers of it. That there may be no mistake here, I shall quote a statement of Klebs, of Prague and a supporter of the germ theory, made at the late Medical Congress in London in an address on "The relations of minute organisms to certain specific diseases." He says "such normal inhabitants of the body (bacteria) may, by alteration of the medium in which they occur, acquire virulent properties and so become causes of disease." This expression of opinion looks to me much more in favour of the physico-chemical than of the germ theory.

But in order to perfect, or at least improve the germ theory it was necessary to examine if any morphological differences existed amongst minute organisms, and especially those said to have been lately found in different specific diseases, chiefly of the lower animals. This apparently is the case, and it seems also that amongst these organisms, difference of form corresponds to difference of function. Now, at first sight this appears a strong proof in favour of the germ theory, but it also seems at least equally so for the other side. These organisms may or may not be simple bacteria, or micrococci and bacilli, as they are now called, morphologically transformed by some chemical change in their medium, but whether or no I certainly should not expect to find identical forms in different infectious fluids, but rather in diverse fluids, diverse forms. Moreover, if different infectious fluids, yield different organic forms, it follows as a corollary that the fluids themselves must have different properties, and may it not be to these properties more than to the peculiar organisms each fluid contains, that their specific infection is due? This at any rate is certain—that, until the alleged specific organisms of such fluids, entirely separated from the fluids with their life conditions maintained intact, and the fluids entirely separated from the organisms with their chemical states unaltered

by oxygen and manipulation during filtration are inoculated into healthy animals separately and the results noted, it should be held as undecided which constitutes the actual virus.

I admit that presently the germ theory seems most in favour, and if its adherents proceed as they are doing, we shall soon have disease germs enough, these being apparently blamed as the cause of every pathological state where they are found, and that is in every pathological specimen, animal and vegetable; and, moreover, for many diseases in which they are not found; and they are always looked on by the germ theorists as the causes of these states and diseases but never as the result.

While speaking thus of the germ theorists it is far from my desire to disparage their arduous and interesting labours. On the other hand the brilliant researches of Pasteur, Klebs, Koch, and others in France and Germany, as well as of Lister, Sanderson, Roberts, and others in Britain, command the admiration of every purely scientific mind, and seem presaging results which, if realised, will be the means of preventing annually, both in man and the lower animals, an enormous amount of disease and an immense number of deaths. At the same time it appears to me that these distinguished savants in many of their investigations tacitly admit the physico-chemical theory while ostensibly discarding it. Also that probably most, at least certainly many of their results already obtained may be as satisfactorily interpreted, and those anticipated as easily realised on the physico-chemical, as on the germ, theory.

Such are a few of the many facts and considerations regarding the nature of zymotic poison. In the brief time at my disposal I could not do the subject half justice, and have been obliged to treat it chiefly in the abstract. Many important points have been unnoticed, such as the cultivation of micro-organisms in different solid and liquid media, in which it is stated their alleged virulence can be maintained, augmented, modified, or destroyed. The ways in which infective matter seems to arise; the modes and channels by which it spreads, and the means and substances used for its destruction, &c., Still I hope that enough has been said to convince you of what was stated at the outset, viz. that the intimate nature of zymotic poison is a subject of vital importance, not only to all medical men but to all humanity.

It is much to be regretted that those of our countrymen who, from their abilities and position are naturally expected to aid in unravelling this complex problem, have, by the late prohibitive enactment regarding experiments on animals, been deprived of the chief means for doing so. I have studied for the last few years without bias, the various arguments in favour of anti-vivisection, and briefly they seem to me to consist essentially of rabid sentiment and mere sophistry, the result of morbid æsthetic conditions. Most medical men admit that some experiments formerly repeated on animals were only of interest in showing certain peculiar known vital phenomena primarily revealed by the experiments, and they willingly admit that such are superseded by the knowledge thereby acquired. But, is medical service perfect? Can the shifting, subtle, and profound intricacies of disease and of therapeutic action, be predicated and formulated like a proposition of Euclid? It would seem so, judging from the Anti-vivisection Act, and not that the birth of scientific medicine was only about forty years ago. As the treatment of disease is partly founded on a knowledge of healthy physiological function, how is this to be perfected but by studying the different organs and their functions during healthy life, which is only practicable by experimenting on animals. Partially conceding that there is already sufficient knowledge on this point for all practical purposes, this cannot however by any means be admitted in regard to pathology and therapeutics,

a knowledge of which is as necessary to the treatment of disease, as is that of the healthy organs and functions. Experimental pathology, as I may term it, is a branch of medical science, from which most favourable results in "preventive medicine" may be expected, and more especially in regard to zymotic affections. Certainly, such results can only be obtained by experiments on the lower animals, unless some of the anti-vivisectionists submit themselves as substitutes. For it will hardly do for them to say that men, women, and children and many useful lower animals, must suffer and die of infections and other maladies, in order that a few frogs and dogs, and cats and rats, may live.

As regards therapeutics, in the progress of which I am more particularly interested, its numberless intricate problems, can unquestionably only be solved by experiments on animals. From the great and universally recognised value of medicinal bodies in the treatment of disease, and from the continual introduction of new chemical preparations and vegetable products, some of which may be of great value when their actions are known, I think that the Anti-vivisection Act presses heavier here than elsewhere. Perhaps some of you may have heard of the introduction of Calabar bean as a medicine, by which Sir Robert Christison in trying its effects on himself, nearly lost his valuable life. Now were an anti-vivisectionist or any of his family to have tetanus, it is probable that they would get the benefit of this experiment. Then again chloral and its hydrate were discovered by Liebig more than forty years since, and a bare account of their preparation and composition in works and organic chemistry, was all that was known of them until about ten years ago, when Liebreich experimented on animals with the hydrate in Virchow's laboratory in Berlin, and thereby discovered its valuable soporific properties. These are now so well known and so largely appreciated throughout the world that whereas, at the time of Liebreich's discovery there were perhaps not more than a few ounces in existence, it is now prepared by the hundred-weight and used everywhere. But the anti-vivisectionists are not consistent. Why suppress experiments on animals indispensable for the acquisition of knowledge to be utilised in lessening disease and saving life, while in many cases neglecting the great cruelties inflicted on them for profit and mere sport. Indeed, the fact that thousands of animals are tortured and killed yearly, solely for sport, is surely, to say the least, a vastly greater infringement of morals than that alleged to be perpetrated by the comparatively slight pain inflicted on comparatively few of them, for beneficent ends. The cruelties to which I allude are demonstrated in deer stalking, in which the noble animal with "his round haunches gored," or a scapula fractured, or a leg broken, or his snout shattered by the leaden missile of the stalker, often escapes to some lone mountain corrie—to die. This is painfully illustrated in Landseer's picture entitled "A random shot," where a wounded hind with its fawn sucking it, lies bleeding and dying on the snow. Such cruelties are also seen in the trapping of ground game where a hare or rabbit may be caught by the leg in the iron teeth of the trap at nightfall and held there till next morning struggling in agony; or it may escape to die a lingering death in its burrow, leaving its mangled limb in the trap. They are also seen in the degrading sport of "drawing the badger," and in that of the rat pit where bets are taken on terriers to kill a number of rats in a given time, and where young terriers are often put to kill rats whose teeth have been extracted to prevent them acting in self-defence. They are also seen in the emasculating of lambs, in which the seminal glands are usually torn and gnawed out in the most cruel and brutal manner by the teeth of the shepherd. Female deer have also sometimes their ovaries removed merely to increase their size and improve their appearance. They are also seen in the well known murder spots of grouse shooting, pigeon shooting, hare coursing, deer

drives and fox hunting; and it may also be said in horse racing. Likewise in the conveying of cattle across the Atlantic, in which the poor animals are often dreadfully knocked about, sea-sick and vomiting, a most painful process for a ruminant, having their legs broken, their horns torn from their sockets, and frequently dying in great numbers. Also in the transport and sale of lobsters, in which these crustaceans are allowed slowly to die, as may often be seen in fishmonger's windows, where they are exposed, still in life, with their appendages fastened to prevent escape. Also in steam-dredging, in which masses of fish die a lingering death, especially the flat fishes, these often living many hours after leaving the water. Also in angling, in which a salmon or trout, probably hooked by the eye, may struggle long with its captor, or perhaps have several hooks of a phantom minnow buried in its palate, and perhaps, after all, escaping with the steel barbs still sticking in its mouth. And in angling with the worm, in which the poor creature usually has its sensitive double chain of nervous ganglia strung on the hook, or its tender skin pierced at intervals with three barbs, as in the "Stewart tackle," designed to torture it as little but as long as possible. Also in angling with the live minnow, in which one hook is buried in its skull, one in its spine, and one at the root of its tail. Other live animals are also used in angling, e.g., frogs, flies, grasshoppers, &c., &c. These facts surely show that the anti-vivisectionists are straining at gnats and swallowing camels, and that, for many reasons, they should be placed in the same rank as the anti-vaccinationists.

THE GERM THEORIES OF DISEASE COMPARED.

By Surg.-Gen. CHAS. A. GORDON, M.D., C.B.,
Honorary Physician to H.M. the Queen.

"THE state of disease is not a radically different condition from that of health. The pathological condition is, to the physiological, simply a prolongation of the limits of variation, higher or lower, proper to each phenomenon of the normal organism, and it can never produce any new phenomenon." (a) Thus is expressed the theory of disease looked at from the standpoint of philosophy. But from the days of Hippocrates, medicine has been separated from philosophy; and here are some of the results of this separation: "Hypothesis heaped on hypothesis, unsupported by observation, based on no truths." (b) How far the last quoted remarks apply to the theory of disease germs, which at present commands a large share of professional attention, remains to be seen. At the meeting of the Medical Congress, one (c) of the eminent men who addressed that body, expressed his views with regard to the phenomena of disease in words not very different in their purport from those quoted in the opening paragraph of the present article. At the same time he spoke of the germ theory in conditional terms, thus: "If the specific diseases be due to organisms, and the hypothetical contagium vivum be a reality, and if the doctrine of evolution," &c., &c. We propose now briefly to summarise a little of what very recently has been adduced for and against this hypothesis, bearing in mind the while that the subject is still in the stage so designated.

And, first, those that are for disease germs. The disastrous disturbances by which wounds and life are threatened, are ultimately due to the intrusion of lower organisms. (d) Drs. Fokker and Naegelli consider that there is only one form of bacteria subject to varieties

and modifications. (e) In anthrax the only agent necessary, or able to produce the disease, is the bacillus anthracis. (f) Everybody who did not believe in the specific nature of germs was wrong. (g) Germs or elements of destruction in the form of microzymes, which are the cause of all fermentation, and the lowest element to which our organism can be reduced. (h) Inoculation of animals, with the virus of pleuro-pneumonia, was stated to be a sure guarantee against that disease. (i) By the theory of germs, means were taken to diminish the chances of infection after great operations; morbid poisons could be attenuated, and by inoculation with the product, virulent diseases prevented. (j) The method of preparation of, and inoculation with the virus of children, cholera, and of splenic fever, was fully described by the greatest advocate of the system. (k) And so on.

2. Against the theory of disease germs are the following:—The figures given as results of treatment of wounds in accordance with the theory, have been slighted. (a) Equally favourable results would have followed the observance of perfect cleanliness. (b) It was said (c) that "the relation of micro-organisms to diseased processes was being exaggerated. Whether bacteria exist only as one form, or in that of several different forms, is a point on which opinions differ. (d) Portions of brain substance contained substances that not unlikely were mistaken for organisms. (e) The hay bacillus acquires virulent properties when cultivated in an albuminous fluid. So does aspergillus. (f) The bacillus anthracis could be converted into hay bacillus, and vice versa. (g) It was stated that this could be explained by an error in manipulation. (h) The transformation of a micrococcus had never been seen; therefore, it was not believed in. (i) It was shown at a meeting of the Academy of Medicine that inoculation with the virus of pleuro-pneumonia was of no benefit whatever. (j) It is said of a very eminent experimenter (k), that he sees germs everywhere. Of animals inoculated by him with saliva from the mouth of a child dead by rabies, all died. Their blood contained myriads of microzymes. Rabbits inoculated with the blood died, and in theirs precisely similar microzymes were found. Further experiments, however, with saliva of children who had died by other diseases, were followed by results precisely similar to the first series. (l) Regarding the *spirillum obermeiri* cases of relapsing fever occur in which competent observers fail to detect spirilla in the blood. Persons were equally inoculated with the blood, no matter whether it contained spirilla or not. Observations on septimic infection go to discredit the ministry of organisms. (m) The doctrine of specific organisms, as the cause of specific diseases, is alluded to as a hypothesis;

its adoption as the *assumption* of such a *theory*. (n) It is noticed as being of the number of theories regarding infectious disease as those of "arrows of Apollo, winged worms, little dragons, spiders," and so on; the power of resisting them, as the *vis medicatrix naturæ*. (a) Drs. West and Jacobi, speaking in the section of diseases of children, said that the presence of bacteria, or other organisms in the membrane of diphtheria, does not prove that they are the cause of that disease. Against the theory of inoculation of cattle with virus of spleen fever, it is stated that the results of experiments differ in French and in English cattle; also, according to breed, and that results obtained on the former do not necessarily hold with regard to the latter. (b) The theory of "anthrax poison" being brought to the surface by virus was shown to be inapplicable. (c) It was pointed out that, with the diminution in mortality by small-pox, which has occurred during recent years, there has been an increase in that by measles and scarlatina, exceeding that which increase of population would account for. (d) It is hardly possible to think of a neutral living organism. (*Monas tuberculosum* of Klebs) being charged with the power of conveying so complex details from one body to another. (e) The public is being universally "fetched" by the simple and attractive notion of numerous common diseases being caused by aerial swarms of organisms which have had, as it were, declared war against mankind. (f)

The references thus given, while they comprise the gist of all that has transpired in arguments adduced in support of the "germ theory," give only a few of those that are brought forward in opposition to that theory. Let us assume, for the sake of illustration, that in a criminal court the prosecution had no more definite evidence in support of a charge than such as is here brought forward in favour of the germ theory, as opposed to that "on the other side." Under such circumstances, is it reasonable to believe that an intelligent jury would pronounce a verdict of guilty against "the prisoner at the bar?" Most assuredly—No.

VIVISECTION.

[COMMUNICATED.]

THE futile but vexatious attack made on Professor Ferrier, by the anti-vivisectionists, will not be without useful results, if it discredits a society composed of sickly philanthropists, and presumptuous busy-bodies, and, by cutting off the stream of subscriptions, puts it out of its power in future to fee an eminent Q.C. to bespatter with abuse a man of science, when he is unrepresented and has no opportunity of meeting the charges unwarrantably brought against him. For fourteen days, between the application for the summons and its hearing, Professor Ferrier had to lie under the imputation of being a law-breaker, and of having performed experiments which were denounced as "terrible" and "shocking," and which the public, so prone to take things on trust, will probably continue to regard in that light notwithstanding the convincing evidence adduced that they were beneficent and deserving of the admiration and praise of all who wish well to their fellow men. It is, we understand, unusual as it certainly is unfair for anyone applying for a summons, to indulge in unnecessary expletives or do more than state the facts which justify the application, and we trust there-

fore that it will be remembered by the medical profession of any borough, the suffrages of which Mr. Waddy may hereafter seek, that he went out of his way to traduce an eminent physician whose sole offence is, that he has laboured to extend the boundaries of knowledge and increase the resources of the healing art.

But the attack on Professor Ferrier will have other advantages besides disgracing a silly society and showing forth a legal luminary and political aspirant in his true colours, for it will prominently direct attention to the whole subject of vivisection, and scattering the prejudices and falsehoods that have been diligently gathered round it, tend to spread just notions respecting it amongst the discerning classes of the community. And it is high time that the whole subject of vivisection should be reconsidered. The Act at present regulating painful experiments on living animals was accepted by the medical profession in 1876, at a time when it might have been readily defeated, with some reluctance, but with the understanding that it would be liberally administered. "The compromise which," as Lord Sherbrook has said "then in the language of the solicitor broke out between the parties," was accepted by the profession, not as involving that there had been the slightest abuse of vivisection in this country, or that there was any need for legislative interference, but rather as insuring to scientific investigators, official protection in their work and freedom from misrepresentation and annoyance. It is almost needless to say that the anticipations which led to the acceptance of the compromise have been woefully disappointed. The Act has been interpreted in the narrowest spirit. Obstacles have been placed in the way of the most necessary and praiseworthy investigations. Physiological and pathological discoveries have been practically forbidden in England. Ardent students have had to visit the Continent in order to solve pressing problems having an immediate bearing on the recognition and treatment of disease. Agitation has not abated. Anti-vivisection literature of the wildest description is still sown broadcast over the country, and now an utterly unfounded charge is trumped up against a distinguished medical man, who is accused of having violated an Act, which men of science at least have been careful to respect. It is clear that the yielding policy—the policy of compromise, has failed signally in this instance, and that it must be changed for bolder and more spirited measures. Those interested in the progress of biological science, cannot any longer submit to have their hands tied while they are subjected to insult and calumny. Further surrender is impossible, and a bold stand must be made for truth and humanity—not purblind but far-seeing humanity. The moment that men of science with no misgivings as to the justice of their cause, but with a natural desire for peace and the conciliation of their ignorant or misguided enemies, show a disposition to concede any point a more determined rush than ever is made on their whole position. When Oliver Twist, in his innocence and timidity took to his heels after the theft of Mr. Brownlow's pocket handkerchief, the actual depredators, the Dodger and Master Bates, as well as all the disreputable characters in the neighbourhood joined in the pursuit of him shouting lustily "Stop Thief!" and so when men of science in guilelessness and dislike to controversy, turn silently from the preposterous charges brought against them, all the cruel classes in the country raise the hue and cry and chase them with howls and execrations, in the hope perhaps of withdrawing attention from their own misdeeds, and gaining cheap applause, as the apostles of tenderness and pity. For the fact cannot be disguised that the ranks of the anti-vivisection army are recruited greatly from what must be designated the cruel classes. They include no doubt some raw soldiers, who are genial but stupid, but they are made up we fear chiefly of levies in whose breasts there is but little of the genuine milk of human kindness. There are to be found the torturers of consciences, who for the lust of priestly power, strips the poor soul of its

natural integuments, lacerate its most sensitive recesses, and plant in it long festering issues. These are the heroic pigeon and pheasant shooters, who kill for the love of the thing, and shatter limbs and nerves and viscera in careless profusion. These are the egotistic females—women one cannot call them—whose delicately strung nerves cannot bear the idea that a rabbit should be poisoned for scientific purposes, and who are willing, therefore, to entail intolerable suffering on future generations of mankind. These are the *connoisseurs* of crimped cod and *pâte de foie gras*, the patrons of the bearing rein, the adulterators of food and drugs, the owners of coffin ships, and many others probably who hope

To compound for sins they are inclined to,
By damning those they have no mind to.

To give way to such opponents of vivisection, is to stultify scientific truth, and encourage further encroachments on its domain. As Virchow has well pointed out, were the attempt to restrict vivisection successful, an active crusade for its abolition would be begun, and after that would come an agitation against mortification. Those who now lament the torments to which, they allege, animals are subject, would then thunder against the desecration of corpses, and denounce our dissecting rooms and post-mortem theatres as places in which ingenuous youth is systematically hardened and demoralised. A firm stand must be made against fanaticism in alliance with ignorance and hypocrisy, and the great truth emphatically proclaimed that experiments on living animals are essential to further advances in medicine and surgery. It is not now to be anticipated or desired that such experiments should be carried on, except under registration and supervision, but guarantees must be obtained that no obstacle should be put in the way of their performance by any competent operator, that no bigoted nor popularity hunting official shall have it in his power to impede the growth of knowledge, and the alleviation of suffering, and that those undertaking such experiments shall be safe from harassment and persecution. There is plenty of solid good sense in the English nation to appreciate the irrefutable arguments in favour of vivisection when they are fairly and plainly stated, and to brush aside the follies of those who would extinguish science in these islands, and rivet on us and our descendants oppressive burdens, which a little judicious experimenting might remove. Hence the importance of reopening the question, and of exposing the fallacies, exaggerations, and cunning devices of the anti-vivisectionists.

And on a question of this kind the argument from authority will have much weight with the British public. It will not be slow to understand that the lay mind is as incompetent to prescribe to medical science its future lines of research as it is to dictate to astronomers what improvements they are to effect in their apparatus, or to chemists, what reagents they are to employ in testing. Medical science knows best what is needful for its further progress; and when 99 per cent. of doctors in the country declare solemnly that experiments on living animals are indispensable to deeper insight into the nature of disease, and to improved methods of treating it, then the loud asseverations of any number of ill-informed out-siders may safely be disregarded. All reasonable beings who have suffered from disease, or seen its effects on those they love, who have felt pain, or mourned over the work of the fell-reaper, who cuts down "the bearded grain at a breath, and the flowers that grow between," wish well to medical science, and hope that the resources of the healing art will be made more and more certain and effective.

There is not one man in ten thousand who, if convinced that the slaughter of a rabbit would instantly relieve him of an agonising toothache, or that the decapitation of one thousand frogs would bring back his hydrophobic child from the gates of death, would not instantly sanction the sacrifice. Is there one in ten thousand, then, who, on its being shown that the

slaughter of a rabbit might lead to the relief, not of an individual pang, but of the throes of generations of future sufferers, or that the mincing up of one thousand frogs would insure the abolition of hydrophobia, would hesitate for one instant to wish God speed to the hand that wrought such beneficent destruction?

How comes it then, it must be demanded again and again, that there is so much opposition to vivisection, not only amongst the small and irresponsible residuum of mankind, who would rather die than shed the blood of a guinea pig, but also amongst generally rational and matter-of-fact people? What is it in a painful experiment on a living animal that is objected to, not by the fanatics, for their cries and conjurations are unanswerable, but by sober-minded persons capable of listening to argument? Not surely the pain itself nor the reaction of the pain on those inflicting it. "The whole creation groaneth and travaileth in pain until now," and it is the law that animals must suffer for man's welfare. Wordsworth has told us that:—

"We must not blend our pleasure or our pride
With suffering of the meanest thing that feels."

but even the gentle Lakist has not maintained that it is unlawful to blend our safety, comfort, and convenience with suffering of any animal in the scale of being even up to the noblest, man himself. And no object of man's pursuit more fully warrants the imposition of suffering upon the lower creatures than the emancipation of the human race from the slavery of disease, or, at least, from some of those morbid fetters which have so long bound it in misery. The medical profession emphatically declares that the infliction of a small amount of suffering on animals in the past has brought unmeasured relief to tens of thousands of men, women, and children racked on beds of sickness and accident, and leaders of the profession, not vain dreamers or braggarts—but men like Lister, Rutherford, Lauder Brunton, Radcliffe, Burdon Sanderson—assure us that they have a full conviction that by the infliction of a little suffering on animals now, they will put within our reach new means of ameliorating the condition of our species. Is it to be endured that such men should be held back from their truly philanthropic enterprise, on account of any abstract proposition that it is unlawful to inflict pain on animals?

The argument that the reaction of the pain inflicted on animals on those who inflict it or on the community that sanctions its infliction is delirious, and tends to demoralise is scarcely more tenable than that which maintains that it is not permissible to give pain to animals on any pretext beyond the obvious necessities of procuring food and raiment at their expense. It may be demonstrated that the infliction of pain on sentient beings does not harden nor deprave those who inflict or sanction it. It is not what a man does but the motive with which he does it that purifies or defiles the mind. To give charity ostentatiously, out of one's superabundance is to cultivate the pharisaical spirit which is detestable, but to relieve distress secretly and with self denial is to encourage Christian virtues. And so to inflict pain for wantonness or personal enjoyment is to corrupt and brutalise the heart, but to inflict it, with the conviction of its necessity and for an assured future good, in the performance of duty or pursuit of truth is really to discipline and ennoble the mind. It has never been argued that the infliction of punishment, which means pain, with a view to the reformation of the individual or the masses is in any way prejudicial to anybody concerned. It would indeed seem to have been publicly recognised that the administration of pain in the form of chastisement to small boys has a dignifying effect on the intellect and character; for it used to be said that no one was fit to be a bishop until he had birched a thousand boys. The head masters of our public schools are daily performing very painful experiments on sentient beings with very problematical advantages, and if we possessed as delicate an instrument for measuring sensation, as we do for measuring the force of muscular

contraction it might be proved that any one of them has caused, through the artificial production of intense cutaneous erythema, more physical suffering than all the vivisections in the kingdom, to say nothing of the distressing mental accompaniments of flogging in a being that looks before and after, which have of course no analogues, in an animal living in the moment and not given to retrospection or anticipation. And yet these men are held in high esteem, and so excellent in this case are the effects, the infliction of pain considered on all the parties concerned, that the bigger boys are encouraged to imitate their example, and flog their smaller and weaker brethren, tunding being defended as a manly and invigorating exercise.

It is the motive with which pain is inflicted that determines its moral effects, and surely in the case of vivisection these motives are of the purest and best. They cannot be classed under love of sport, nor mechanical subservience to custom, nor personal aggrandisement, nor craving for the fleeting breath of popularity, but must be recognised as the love of truth, and a desire to improve the condition of humanity and free it from some of its most grievous burdens, and if any motives can exalt and sublimate human action, these surely are they.

Clinical Records.

MEATH HOSPITAL AND CO. DUBLIN
INFIRMARY.

Brief Notes of Operations.

Under the Care of Mr. LAMBERT H. ORMSBY,
F.R.C.S.,

Lecturer on Clinical and Operative Surgery.

(For these notes we are indebted to Mr. PERCY NEWELL.)

OPERATION I.—For Necrosis of Lower Jaw.—Kate K., *æt* 13, an exceedingly weak, unhealthy looking girl, was admitted into the Meath Hospital on the 12th Oct., suffering from necrosis of lower jaw, extending nearly from symphysis to angle. *History*—For nearly three years she has been suffering from abscesses continually forming along the lower jaw, and when formed they usually opened, leaving unhealthy sinuses behind which discharged a thin kind of ichorous pus. On examination it was found that a large piece of the bone was quite bare and loose.

Operation performed for Sequestrotomy.—An incision was made along the ramus of the jaw uniting the sinuses and with the aid of the necrosis forceps, bone forceps, and elevator, a large portion of the dead bone was successfully removed from the outside. The mouth was now opened and it was found that there was some more necrosed bone still remaining, which was loose to a certain extent, and to which was attached two of the molar teeth. After a good deal of gentle manipulation this further portion was removed through the mouth. A profuse hæmorrhage followed. This was arrested by plugging the wound, which was considerable in size, with lint. The girl made a good recovery, and was discharged from the hospital in a fortnight.

OPERATION II.—For Fibrous Anchylosis of Elbow.—Christopher R., labourer, *æt* 30, was admitted to Meath Hospital, Oct. 8th, suffering from fibrous or false ankylosis of right elbow joint. *History*—He states that about two months ago he got a fall out of a cart on his elbow, which probably was fractured above the condyles of the humerus. He went to a "country bone-setter," who set his arm in a perfectly straight position from the shoulder down. The patient felt this a most inconvenient and useless position for his arm; not being able to work or lift food to his mouth. After close examination, Mr. Ormsby decided to break up the fibrous extra-articular adhesions with passive motion under ether, and if motion could not be restored to the joint, the forearm could be placed in a more useful condition for him, viz., in the angular position. Accordingly, on the 12th Oct., he was placed fully under the influence of ether, and when perfectly unconscious, it was found that there was slight motion in the joint, although of a very limited character, but it was

quite sufficient to prove the ankylosis was the false variety, and not the true. By gradual force, the operator slowly but surely, broke up the various adhesions fixing the joint, so that from the completely extended position the forearm was flexed so as to allow the palm of the hand to touch the shoulder. After the forearm was thus flexed and extended on two or three occasions, the limb was bandaged to an angular splint and thus retained. Considerable swelling followed this passive motion, which was treated with cold evaporating lotions and perfect rest enjoined. After some few days the pain and swelling had subsided, and he began to use the arm. In ten days he was again put under ether, and the joint moved again in the same way, after which he could move the joint very fairly, as well as put food to his mouth which he could not do previous to the operation.

OPERATION III.—Tenotomy of Long Flexor of Thumb.—Mary A., *æt* 10, was admitted to Meath Hospital, Oct. 12th suffering from extreme flexion of second phalanx of right thumb due to contraction of the tendon of the flexor pollicis longus. *History*—States that about six weeks ago she received an injury to the top of her thumb, and from that date it began to contract on the palm of the hand, disabling her to a great extent. On examination it was found that the motion in the joint appeared to be in no way impaired, but on attempting to extend the second phalanx, it was prevented by the contracted tendon of long flexor, which was very prominent and hard. Mr. Ormsby fearing, by instrumental pressure it would take a very long time to get the thumb in position, determined to divide the tendon. Accordingly, the girl was placed fully under the influence of ether, and Mr. Ormsby placed a very sharp tenotome under the tendon, and quickly turned the cutting edge against the contraction, which gave way with a perceptible snap. A dossil of lint, and a strip of plaster was placed over the tenotome puncture, no bleeding followed, and a very small flat metallic padded splint was bandaged to the thumb. After the splint was constantly applied for three weeks, the thumb was in a perfectly extended position, and the patient at the end of six weeks had power to flex it as well, showing the tendon must have united and thus regained its utility.

OPERATION IV.—Removal of Warts from Glans Penis.—Thomas M., *æt* 20, was admitted into the Meath Hospital, suffering from a most extraordinary crop of warty growths around and covering over completely the glans penis, due to continued attacks of gonorrhœa, and dirt accumulation, &c. On examination it was found that the warts extended all over the glans and affected the inside of the prepuce as well. He never had chancres, but had repeated attacks of gonorrhœa. It was decided to remove this crop of warts. Accordingly, he was placed fully under the influence of ether, and the operator, by means of a very sharp curved scissors, was able to remove these extraordinary warty excrescences. The parts being very vascular, a great deal of hæmorrhage followed, but it was soon controlled by the application of strips of lint steeped in a solution of tinct. ferri perchlor. The man made a very good recovery.

Special.

MEDICINE IN CHINA.—II.

Ague.—On the subject of ague or intermittent fe much information of a peculiar and interesting kind is found in these reports. The popular name in Peking for ague is *yan-tze*, the book name, *niö-chi*, from the resemblance in its treatment of its subjects to a harsh and cruel man. Several kinds of ague are specified in Chinese medical works. The principal of these are arranged according to assigned cause, for, unlike their Western representatives, the Chinese physicians admit the power of several causative influences besides that indicated by the term *malaria*, or its equivalent, *fung-skui*; that is, air and water, otherwise "climate." Thus we meet with ague from wind, from cold, from heat, damp, "phlegm," food, excessive exertion of body or mind, spirits or devils, epidemic, pestilential vapours issuing from deep valleys, and so on. The causes of the cold and hot stages is traced to a

want of harmony between the two principles of Nature, the *yin* and the *yang*, this explanation perhaps, not more indefinite—and in its nature more abstract—than are some of those theories which find acceptance elsewhere than in China.

The symptoms of ague are minutely and very correctly described in all Chinese medical books, from 2,600 B.C. down to the present dynasty. Thus authentic experience with reference to the affection is carried back to a period of immense antiquity. But it cannot be said that advance has taken place in the methods followed if, as in the West, the significance of the terms "change" and "advance" is held to be synonymous. The remedies employed in the treatment of ague are those that have been used for the same purpose during the last 3,000 years. Full details with regard to them are given in the reports under notice; their composition can be only glanced at. In cases of ague, during the perspiration stage, a preparation is administered composed of cinnamon, *libanotis* root and liquorice (glycyrrhiza). In cases where perspiration is absent, the same with the addition of *ephedra*. In the ordinary and regular quotidian form, a combination of the root of *Bupleurum octotridiatra* cinnamon, scutellaria, ginseng (*Panax ginseng*), *pæonia albiflora*, an armroot (*arum macrori*), prunice, ginger, and jujubes (*Zizyphus jujuba*). In cases of day ague the treatment differs from that for night. One remedy consists of ginger, peppermint, honey and water—a little camphor in addition, should these prove "too hot." Other remedies are enumerated, some palpably inert, others extremely offensive in their nature. From the composition of those enumerated, however, the circumstance transpires that the remedies most trusted to are those the properties of which are severally aromatic, antispasmodic, and tonic.

9. *Dysentery*.—The occurrence of dysentery in China is one of the great dangers to which sailors visiting ports, and residents in that country are exposed. Among seafaring persons—more especially those of scorbutic diathesis—it is generally severe, and often fatal; in foreigners on shore liable to hepatic complications, and showing a tendency to become chronic. Dysentery and malarial fevers are frequently present in the same individual. They chiefly prevail during the same period of the year, namely, that in which marsh miasms are most abundant. They are, in fact, considered to be results of seasonal and climatic causes.

In the treatment of dysentery in China, ipecacuanha in large doses has been administered, as in Europe. In particular cases benefit has rapidly followed; in others the results have been less satisfactory. The native remedy, which has attained the highest reputation in the treatment of dysentery as that disease occurs in China, is the *Ailanthus glandulosa*, the actual properties of the plant being that it is intensely bitter and astringent; also that it is powerfully anthelmintic. As is natural to assume from its properties, it is chiefly employed in the chronic form of dysentery. In that form it is administered combined with aromatics, including mace, levisium, liquorice, together with other substances, as *Lonicera chinensis* and charcoal of *carthamus tinctorius*,—the combination taken in rice water while fasting, the diet of the patient to consist of milk and rice. This *regime* has been directed with success by physicians of the French Legation in Peking. In several respects it bears analogy to the treatment of chronic cases by the rind of the *Garcinia mangostena* in the Straits; by powdered bael (*Aegle marmelos*) in India.

10. *Small-pox*.—According to writings quoted in the reports before us, the history of small-pox is traced back in China to about A.D. 317-40. But as to the manner of its

first occurrence, or its original source, if, indeed, that were extraneous, information is necessarily indefinite.

Inoculation.—The employment of inoculation as a protection against small-pox has been followed in China for ages. Vaccination is rapidly superseding that method: yet among many natives there exists this plausible objection against the latter, that without a few marks as evidence of having passed through small-pox, a marriageable woman is wanting in one of her chief qualifications. But the practice of vaccination is rapidly spreading, nevertheless; and more especially in Canton in the south, and Peking in the far north, of China.

11. *Peculiar Diseases*.—*Sprue*.—The disease so named has long been known in India and Java. The term is sometimes applied to the thrush of infants associated with the development of *oidium albicans* in the mouth. Sprue, however, is entirely confined to adults. Its symptoms are referable, 1. To a remitting inflammation of the mouth and alimentary canal generally. 2. To diarrhoea and irregular action of the bowels. 3. To anæmia and general atrophy. It is peculiar to hot climates. During an exacerbation the tongue is more or less swollen, papillæ elevated, shallow ulcers on cheeks, tongue, and lips; saliva rapidly accumulating, pours from the mouth while being examined; tongue abnormally clean; no fætor. The œsophagus becoming implicated, renders swallowing difficult. Both the inflammation in the mouth and the diarrhoea are periodic. At times the diarrhoea is semi-choleraic in character, the attacks at night, occasionally also with diarrhoea; there is great sense of languor, tympanitis, and borborygmi. The evacuations pale, clayey, frothy. There is great emaciation, the patient is feeble, irritable, incapable of much mental effort, and anæmic. The progress of the disease is slow. Removal to a cold climate is absolutely necessary. Medicine and diet, although they may mitigate, will not cure the disease so long as the patient remains under the conditions in which the disease was acquired.

The cause of sprue is the general unsuitability of the European constitution to tropical climates. In China age and residence have a marked influence as predisposing causes; of five cases recorded the patients were over thirty-five years of age, and had been over ten years in the country; their habits differed—from free livers to teetotalers. At Shanghai, and other northern places, patients improve during the cold weather. The reporter has never seen it in a native. In Batavia the affection is generally associated with cirrhosis, or other disease of the liver.

In the treatment, bismuth and strychnia during the remissions, and bismuth and morphia during the exacerbations, are of some service as palliatives. Wine and spirits should be given much diluted. Other remedies recommended are grey powder, soda and rhubarb, taraxacum with alkali.

12. *Rabies*.—The occurrence of rabies in dogs in China depends not upon ill-usage to which these animals are subjected to. Were this the case, it would be ever present among the curs that live upon foul garbage in city lanes and streets, to speak not of other places no less foul. The several methods adopted by the Chinese of treating hydrophobia are carefully detailed in the Customs' reports. According to one of these, in order to guard against the affection, the newly-inflicted wound must be treated with moxa; then the remedy *yuh tsin* applied, while internally, first the *Foo wei san*, and next the *Hoo peih yu san* are successively administered. The constituents of the former are orris root (*Iris blorentina*), arum pentaphyllum, and another species (*Pek-lu-tze*), urtica tuberosa, angelica, and libanotis (*Libanotis Sibirica*)—equal parts. The combination triturated so as to form a powder, and moistened. The second remedy named,

that is, *Foo wei san*, consists of cantharides, 1 fly, a soft yellow earth, one oz., realgar, 1-10th oz., musk, 1-50th oz. Add one Spanish fly for every day that has transpired since the bite up to the seventh day, but on the tenth, and afterwards, add ten flies to the mixture. The third, namely, *Hoo pek yah san*, is thus composed: yellow earth, 6 oz.; liquorice, 1 oz.; amber, $\frac{1}{2}$ oz.; indigo, 1-12th oz. The dose, 1-3rd oz., "dissolved in water in which the rush has been boiled." Another remedy—and it is said to be infallible—is composed of musk, 16 grammes; native and artificial cinchar, of each 20 grammes. These are powdered, mixed, and administered in a spoonful of rice spirit (arrack). At the end of two or three hours sound sleep, followed by profuse perspiration, follows, and then the dose is to be repeated. But unhappily, a tual statistics of recoveries by all such means have yet to be supplied.

13. *Formication*.—One of the "peculiar" affections to which Chinese in Canton are subject is described as general formication. It appears to be undescribed except in the reports before us. It is there alluded to after this manner. Sensation like the crawling of ants over different parts of the body. These sensations come and go, except in aggravated cases, when they are felt nearly constantly. They are apt to be worst at night; they occur in such weather as usually produce neuralgic pains; they are excited by heat and atmospheric changes, by causes acting upon the mind. Cold has a soothing influence. It appears to be peculiar to the native Chinese; both sexes are about equally liable to attack; the general health of the patients otherwise good. The native physicians recommend a tonic course of treatment and mental relaxation. In its nature the affection is considered as allied somewhat to neuralgia.

14. *Peculiar Affections of the Throat*.—In the far north of China a peculiar form of disease affecting the throat is met with among the natives. It prevails during the winter season, and so far has been met with at no other Treaty port than *Neuchawang*. Its course is somewhat thus: A chill is experienced; then severe fever, lasting a few days; discomfort in the upper part of the mouth; sensation as if something were coughed up; on fourth or fifth day of illness the mucous membrane at the back of the pharynx seems to have disappeared, so completely has it lost its distinctive character. The surface looks as if a dry sponge had been applied, and the mucous membrane rubbed off; what remains of it is dry, shining, and looks as if stretched. Then comes a thin white membrane, which exudes from the part affected, and is coughed up; the exudation, at first white and thin, becomes yellowish and thick. The mucous membrane throughout the mouth and tonsils remains healthy, or very slightly affected. Associated with this affection there is great physical debility. A distinguishing feature is the liability of the patient to relapses.

The treatment employed consisted in steaming the throat with hot water with a little carbolic acid; then gargles containing opium, permanganate of potass or sulphurous acid; internally, phosphates, stimulants, and nourishing food, were given. The affection may or may not be associated with pulmonary disease.

15. *Dengue Fever*.—In 1872 an epidemic of dengue fever occurred in various parts of China. In the month of August of that year it appeared at Amoy, its occurrence was accounted for on the assumption that it was imported by returning emigrants from the Straits Settlements, where, as also in India, it had prevailed during several months. The native physicians at first looked upon the affection as a form of measles. Their theory is, that every person is liable to

three attacks of measles, in Chinese *Tchoot-pia* during his lifetime—twice before he has the small-pox, and once afterwards. When dengue appeared it was looked upon as being the second of such attacks. But the occurrence of the rheumatic pains with eruption in the person of a leading "authority" on the subject induced a change of opinion on his part, this, notwithstanding his national belief that all things new are *old*. Various names accordingly were given to the disease now become epidemic, as *Hong-pia*, or wind measles; *Sin-khi*, the new disease; "*Si-khi*," the seasonal epidemic; *Hong-khi*, the rheumatic disease, and so on. The disease rapidly spread in Amoy; business became in consequence interrupted, coolies, boatmen, and native merchants being nearly all prostrated with it, and not alone the natives, but foreign residents also suffered by it; crews of ships in harbour, as well as persons on shore. From Amoy the epidemic spread to places around. And yet, Foochow, Swatow, and Formosa, so far, remained exempt, notwithstanding that, between those places, India and the Straits communication was frequent and open.

THE HOSPITAL COMMISSION.

THE following appointments to the Governmental Inquiry Commission on the accommodation and administration of hospitals were officially gazetted on Friday last:—Lord Blachford, Sir J. Paget, Sir R. Alcock, Mr. W. Peel, M.P., Dr. J. Burdon Sanderson, Dr. A. Carpenter, Dr. W. H. Broadbent, and Mr. J. Hutchinson. The nature and objects of the inquiry are thus set forth:—

"The nature, extent, and sufficiency of the hospital accommodation for small-pox and fever patients provided by the Managers of the Metropolitan Asylum Board, and the several Vestries and District Boards in the Metropolis, including the Commissioners of Sewers for the City of London.

"The relative advantages and disadvantages to patients and the public of providing for small-pox and fever cases, whether amongst persons of the pauper class, or persons of the non-pauper class without proper means of isolation, or both, by a limited number of hospitals for the whole metropolis under one authority, such as the Managers of the Metropolitan Asylum District, or by parochial and district hospitals, under vestries and district boards.

"The expediency of continuing the several existing small-pox and fever hospitals now under the Managers of the Metropolitan Asylum District; or if it be considered desirable that any should be closed, the accommodation for small-pox and fever cases which should be substituted.

"The expediency of the Managers of the Metropolitan Asylum District establishing additional hospitals and of making special provision for convalescent cases.

"The conditions and limitations under which the hospitals provided by the managers should be continued, and the general conditions and limitations which should be observed in the case of the establishment of new hospitals, whether by the Managers or any other authority, so as to insure as far as practicable, the recovery of the patients and the protection of the public against contagion.

"The operation of the Acts relating to the establishment of hospitals for small-pox and fever patients in the Metropolis, and the provisions, if any, required for the acquisition of sites for such hospitals, whether by agreement or otherwise; and for the protection of the authorities providing small-pox and fever hospitals, subject to the same being conducted with reasonable care, and according to prescribed regulations, from liability to legal proceedings, so as to secure the public

against the loss of the benefits arising from such institutions ; and to make such suggestions as you may deem expedient in connection with all or any of the matters aforesaid."

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

COXALGIA.—At the Société de Chirurgie M. Auger drew the attention of the members to the theory of M. Verneuil in reference to the part played by the muscles of the joint in coxalgia, and endeavoured, by citing a few observations, to oppose the assertion of Verneuil, that cases of relapse in dry coxalgia were due to muscular atrophy and contraction. A little girl, *set.* 6, affected with coxalgia, was treated for several years. In the horizontal position the hip presented no flattening, there was no flexion of the leg, and the ordinary movements of the joint were hardly compromised. But, and this was most striking, there was a lengthening of half an inch. In walking, this lengthening became apparent, and the gluteal muscles were neither contracted nor atrophied. M. Auger believed this to be a case in which the theory of his colleague was not applicable. He (M. Auger) considered that everything depended on the state of the articulation, and that in it was to be found the cause of the different changes witnessed in this disease. M. Verneuil replying, said that in presenting his case (cited last week) to the Société, he did not intend to bring into discussion the whole history of coxalgia. He presented to the members a peculiar case, and endeavoured to explain it in the most natural manner. He did not pretend to speak of the vicious attitudes that the limb takes when the articular surfaces are affected or destroyed. M. le Dentu saw a case analogous to that of the last member. For six years he has been treating a little girl, *set.* 13, for coxalgia by an immovable apparatus, and considered the affection cured. A short time afterwards the mother perceived that the great trochanter of the affected limb was more projective than the other, and that the hip was flattened. Having examined the child, M. le Dentu found that the thigh was slightly flexed on the pelvis, and that there was a beginning of flattening. After some time the flexion became so great that for cible extension had to be practised, which was done under chloroform. During the operation, the resistance being so great, a sensation of tearing was felt. Was it from the ligaments, or the muscles? The child was put into an apparatus, and the limb made a good recovery. The muscles were not atrophied. M. Trélat never saw but two cases cured without ankylosis. M. Ollier considered that relapse was the rule in coxalgia, even after four or five years of apparent cure, and consequently ankylosis was, in his mind, the most fortunate result of treatment. The discussion was concluded as it was commenced, by M. Auger, who agreed thoroughly with MM. Trélat and Ollier, as to the frequency of relapse, and his object in bringing forward his communication, was to oppose the theory of M. Verneuil, who attributed the vicious attitudes of coxalgia alone to the contraction and subsequent atrophy of certain groups of peri-articular muscles, whilst in reality, these attitudes depended on articular lesions.

STRETCHING OF THE LINGUAL NERVE.—M. le Dentu presented a woman, *set.* 76, who suffered from *tic-douloureux* of the face for several years. The pain, which had become intolerable, was seated principally in left temporal region, the jaw, and the corresponding half of the tongue. The inferior lingual nerve was stretched, and the result was highly satisfactory. Thirteen days ago the operation was performed, and since then, the patient had no return of the pain. The nerve was elongated by half an inch. M. Incaise insisted upon the danger of stretching the tri-facial nerve. He had studied the effects of pulling on the superior maxillary nerve in ablation of superior maxillary bone, and he had seen very grave accidents,—trophic troubles, &c. In one case the eye of the side operated on, suppurated. M. le Dentu replied, that he was aware of these accidents, and consequently drew very gently upon the nerves.

HYPogastric LITHOTOMY.—M. Monod made a verbal report upon a communication of one of his colleagues, relative to two cases of hypogastric lithotomy. The first was that of a man affected with an ankylosis, the result of an old coxalgia, and which rendered the perineal section impossible. The calculus was not very voluminous, and weighed but six drachms. Lithotomy being practised above the pubis and the stone extracted, the wound was not closed by sutures, a drainage tube was inserted, and compresses of spirits of camphor applied. The next day a catheter was passed. After the third day of the operation the urine no longer flowed by the wound, and at the end of five weeks cicatrization was complete. The second case was that of a young boy of fifteen, and the operation was similar to that in the first case with this exception, the operator introduced an air-bag into the rectum, so as to throw forward the bladder. Eleven days afterwards the urine flowed by the natural channel, and in eighteen days the cure was definitely effected. The operator, encouraged by these

two successful cases, will to-day only admit of lithotomy, or hypogastric lithotomy. M. Monod, at the Necker Hospital, had occasion to practise three times hypogastric lithotomy, and the result in each case was unfortunate. The first was that of a man, *set.* 63, who had a very voluminous calculus. The extraction was easy, and the wound was sutured with all the necessary precautions. He placed a drain in the lower part of the incision, and a catheter *à demeure* in the bladder. All went well until the patient was attacked with erysipelas, which carried him off very rapidly. In the second case the patient died five days after the operation. No peritonitis could be found, but there was a little pus in the cellular tissue in the front of bladder. In the third case the patient succumbed also on the fifth day to a dangerous abscess of the pre-vesical cavity. M. Després observed that he published four years ago the successful result of two cases in which the operation in question was performed by a provincial surgeon. But the cases were those of children or very young subjects. It is not at all the same with adults, and above all with the old, they succumb, everyone to the hypogastric section. However, if he had a man of robust constitution, and of about fifty years of age, who had a stone of moderate size, he would prefer lithotomy above the pubis to that practised in the perineum. It is a very easy operation, but it should not be practised on the aged.

SUBCUTANEOUS INJECTION OF WATER IN PHTHISIS.—M. Raymond Tripier employs subcutaneous injections of pure water to prevent the vomiting of food in phthical patients. For this end, he injects over the epigastrium a Pravaz syringe-ful of very cold water before or after a meal. Under the influence of these injections, he has often seen the vomiting, which had resisted every other treatment, cease. M. Tripier has treated with success in the same manner the vomiting of certain dyspeptics, especially that of nervous females who dread the employment of morphine.

Transactions of Societies.

THE MEDICAL TEMPERANCE ASSOCIATION.

At the quarterly meeting of the members of this association held in the rooms of the Medical Society of London, Dr. B. W. RICHARDSON, F.R.S., the President, in the chair, Dr. NORMAN KERR read a paper on

THE USE OF STIMULANTS IN WORKHOUSES.

Dr. Norman Kerr treated the subject under three heads. 1. The officers' beer ration. 2. The beer allowance to healthy paupers. 3. The use of intoxicating drinks in the treatment of the sick poor. After pointing out that the presence of drink impaired the discipline, and tended to disturb the good order in workhouses, he strongly urged the entire withdrawal of the beer ration from the official staff, with a reasonable allowance of money instead. The allowance of beer to the healthy pauper, sometimes on the plea of work, was strongly objected to by Dr. Kerr, who held that the practice was condemned alike by many intelligent boards of guardians and by the Local Government Board. The medical prescription of strong drink to sick inmates was an entirely different and independent question, and ought to be considered without reference to any opinion one might have on the action of alcohol in health. There was no method in the medical use of stimulants in workhouses. In one union none would be given, and in another the value of £4 6s. 5d. per inmates would be prescribed. Dr. Kerr gave typical examples of this contradictory and confused prescription of alcohol from the returns affecting unions in England, Scotland, Ireland, and Wales. There was no evidence as yet to show what effect non-alcoholic treatment exercised on life or on disease in poor-houses, some unions consuming no liquor showing a higher percentage of death than other unions where alcohol was administered profusely. They knew nothing about the truth, because hitherto there had been no data complete and full enough to warrant any opinion whatever. Dr. Kerr did not plead for the total disuse of alcohol as a medicine, but for its careful and guarded prescription in accurately defined doses, for a definite purpose, and for the occasion only. He urgently appealed to his colleagues to order alcoholic drinks as cautiously as they did other powerful and dangerous drugs. He entreated his colleagues for their own reputation, for the credit of the profession, and for the benefit of their patients to seriously study the question of alcohol. Their knowledge of the nature of the drug, and of its action on the physical and mental constitution, had of late years been rapidly increasing. One lesson they ought all to take to

heart was, that it was a powerful and dangerous remedy, but too apt in many cases to prove more fatal than the original disease.

The discussion was opened by Dr. DRYSDALE, who said that no information with regard to the effect of alcohol upon disease could be gained from the archives of the Poor-law authorities. He was decidedly against giving alcohol to people in workhouses who were in good health, for he could conceive no greater inducement to the poor to go there than to give them that which perhaps had brought them into the condition which required relief.

Dr. ROGERS, President of the Poor-law Officers' Association, and medical officer to the Westminister Union, said he had not been thirty-five years a workhouse officer without seeing the consequences of intemperance to a degree which was perfectly horrible. At the same time he must complain that total abstinence were not fair in dropping down so heavily upon workhouse medical officers, when the same abuses (if they were abuses) existed in the hospitals. Workhouses were not places, as Dr. Drysdale supposed, where luxuries were served out to paupers, but he had found it judicious to give a little alcoholic drink as a reward for special service in carrying out the ordinary workhouse duties. Boards of guardians were too ready to come down upon medical officers to require assistance from without. Create a public opinion in favour of a non-alcoholic régime in workhouses, and then it could be easily carried out. In one case where a medical officer had denied the paupers any stimulant whatever, he based a claim for an increased stipend for himself, on the fact that he had saved the ratepayers a considerable sum of money.

Dr. RIDGE pointed out that Dr. Kerr had deprecated any attack upon workhouse medical officers, and that the paper fully recognised the difficulty of those gentlemen going against either public opinion, or the will of their respective Boards. The administration of alcohol to healthy paupers in Canada was quite unknown, and he believed it was also unknown in most parts of North America. He thought that much could be done by offering substitutes for beer.

Surgeon-General FRANCIS said that at the Wandsworth and Clapham Infirmary where the expenditure on stimulants had been reduced from £496 18s. 9d. in 1877 to £58 13s. 11d. in 1881 there was a reduction in the death-rate in the latter year, but the increased cost of milk was £50.

Dr. SCATLIFFF observed that the difference between workhouses and hospitals was this—that the workhouses were supported out of the rates, whereas the hospitals were supported by endowments or voluntary contributions.

Dr. RICHARDSON said he would not deprive paupers of any luxury, if it were not a luxury that was conducive to harm. The workhouse was not a desirable home, as could be seen by the instinctive horror of the poor to enter it. The evidence as yet adduced as to whether alcohol decreased or increased mortality was wanting in completeness, and unless some difference could be made in collecting the facts, it would be a long period before they could submit them in a thoroughly satisfactory form. He agreed with Dr. Rogers in thinking it unfair that one class of medical practitioners should be subjected to criticism, and the other not.

A vote of thanks to Dr. Kerr closed the meeting.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, NOVEMBER 7TH.

The President, MR. THOS. ARNOLD ROGERS, in the chair.

Specimens having been exhibited and casual communications read by Messrs. S. J. Hutchinson, J. R. Mummery, Chas. Jones and Lawrence Read,

Dr. B. W. RICHARDSON, F.R.S., read the paper of the evening on

THE CAUSES OF DENTAL CARIES, CONSTITUTIONAL AND LOCAL.

The present widespread prevalence of dental caries was, he said, a matter of more than mere professional, it was of national importance. For some years past he had noted on his clinical records the condition of the teeth of the patients who came before him, and their result of these inquiries had astonished him not a little. He found that of over 4,000 persons, of both sexes and of all ages, over 80 per cent. were

affected more or less severely with dental caries, whilst it was rare to meet with a person in whom both sets were altogether free from the disease. He believed also, that it was now more prevalent among the young, than it was twenty-two years ago, when he commenced medical practice. For such a general prevalence of disease general causes must be looked for, and there were two such which he believed to be of chief importance, viz., Hereditary Syphilis and Dyspepsia. With regard to the first, he quoted the statements of Prof. Gross and Dr. Holland, respecting the proportion of the adult population in the United States and in Great Britain respectively, who acquire the primary disease estimated in each case at about 1 in 8. Contracted in adult life syphilis did not materially affect the teeth, but the hereditary constitution bequeathed by it was undoubtedly indicated in the next generation by disease of the teeth and by a constitutional condition in which caries was readily developed. It was hard to say whether dyspepsia should be placed before or after syphilis in point of importance. The form of the disease which produced the greatest amount of evil, was that which was induced in the first months of life by improper feeding. In children who were deprived of their natural food, the tissues generally were improperly constructed; and although in the case of those which are constantly undergoing renewal some of this harm might be redeemed; in the case of such structures as the teeth, made for the whole of life in a few short months, perfection was impossible if the start was bad. Dr. Richardson did not think that the strumous or tuberculous diathesis caused of themselves any marked tendency to caries; nor did he find that the epidemic diseases of children had any such effect, though this had been asserted. Passing on to speak of local causes, he mentioned four, viz., the action of heated fluids taken into the mouth, the action of acids upon the teeth, deficient cleanliness of the teeth, and exposure of the teeth to the action of certain chemical substances during work at some special occupations. He believed, however, that these causes were of comparatively slight importance, that caries was rarely of purely local origin, though where there was a low state of nutrition within the tooth very slight external causes, acting physically or chemically, would produce serious results. In conclusion, he urged upon the dental profession the importance of impressing upon all with whom it came in contact the necessity of leading a more natural life if they wished to exorcise the terrible disease which was demoralising civilised humanity, and of assisting to promulgate the natural law that it was the duty of every mother of whatever rank to nurse her child and gradually to lead its vital steps into healthy independent existence.

A prolonged discussion followed.

THE annual rate of mortality last week in the principal large towns of the United Kingdom averaged 22.4 per 1,000 of their population, were in—Leicester 11, Wolverhampton 13, Bradford 15, Norwich 16, Plymouth 16, Sunderland 16, Oldham 16, Newcastle-on-Tyne 20, Portsmouth 20, Sheffield 21, Brighton 21, Leeds 21, Birmingham 21, Dublin 21, Edinburgh 21, London 22, Glasgow 23, Bristol 23, Nottingham 24, Manchester 24, Liverpool 28, Salford 29, and Hull 30.

FROM diseases of the zymotic class in the large towns last week scarlet fever showed the largest proportional fatality in Hull, Nottingham, and Brighton; 36 more fatal cases were recorded in Hull, in which town no fewer than 429 have occurred since the beginning of July. Measles showed fatal prevalence in Liverpool and Manchester. The 45 deaths from diphtheria included 23 in London, 8 in Glasgow, and 5 in Portsmouth. The highest death-rates from "fever" occurred in Brighton, Sunderland, Portsmouth, and Hull. Small-pox caused 29 more deaths in London and its outer ring of suburban districts, and one in Oldham; no fatal case of this disease was registered in any of the other large towns.

WEDNESDAY, NOVEMBER 23, 1881.

THE ANTI-VIVISECTIONIST COLLAPSE.

As we ventured to predict in our issue for Nov. 9th he prosecution of Dr. Ferrier by the Anti-Vivisectionists ended in a miserable collapse, the result of their application for a summons having been dismissal of the case. So far the end must be regarded as satisfactory, but none the less there will remain in the mind of every member of the profession a keen sense of the insult offered, not indeed to Dr. Ferrier personally, but to the whole body of scientific inquirers. Certain features of the anti-vivisection crusade have been brought into prominence during the past fortnight, which it might be almost expected would tend to a reaction among the forces of obstruction, were it not hopeless to anticipate any change in the tactics possible only to the ignorant and the fanatical. Low vulgar abuse has been resorted to in many instances, and several well-known physiologists and practitioners have been marked out as objects of vituperation by the uneducated mob who form the majority of the party of hindrance. A revival of the period when Lord Carnarvon's Bill was before Parliament has been witnessed in a small way, and the same species of attack has been resorted to by some at least of the number who, five years ago, yelled their ribald insults against the advance of knowledge. Nor

have the unknown masses alone maintained the cry, for, in a less disgusting, but no less partial manner, many of the lay papers have hastened to ally themselves with the advocates of stagnation. Prominent among them the *Daily News* may be mentioned, this organ having commented on the proceedings at Bow Street in a way which indicated either the most sublime ignorance, or intentional misrepresentation, of the working of the Act. The *Daily News* of Friday morning assured its readers that the charge against Dr. Ferrier had been misunderstood, and that, further, licenses under the Act were never refused to scientific men of the standing of Professor Yeo or Professor Ferrier. This statement may, of course, have been made in ignorance, but we are informed by a correspondent that when opportunity of correcting it was given to the editor of the *Daily News*, he refused to avail himself of it, and thereby maintained a position utterly misleading and partisan. So long, of course, as the organs of public opinion will persist in misinforming their readers, so long will the attempt to put the truth in scientific matters before the public be a futile endeavour.

The occasion offered at the present time of vigorously pursuing a plan of enlightenment and of reform in the question of experimental research, is one that it would be unwise to neglect; and while meetings are being held—as we feel sure they will be held—to express sympathy with Dr. Ferrier, opportunity may very well be taken also to arrange a system of universal instruction on the aims and means of physiological and medical science. Evidence is abundantly forthcoming to prove that most of the blind infatuation which animates the proceedings of various societies organised for the so-called protection of dumb animals, is the outcome of ignorance. Excited by the example of a very few persons placed in high positions, but who are the unfortunate subjects of hysterical and hyper-emotional manifestations, the crowd confidently lend their money and their voice to swell the tide of agitation. Hitherto the medical profession has been content to look on and watch with feelings of amused contempt the miserable exhibitions thus afforded, but now a time has come when prompt and effectual action should replace the passive indifference of the past. Not only is the study of scientific physiology rapidly dying out in this country, but the means whereby measures of remedial efficacy in disease have been perfected, are no longer a subject of study among our ablest observers. This is a question of the first importance; not to our pre-eminence in the ranks of science alone, but more especially to us as professors of the art of medicine. The people themselves are primarily interested herein, moreover, and it needs only a determined attempt to put the masses in possession of the real facts of the case as they chiefly affect themselves, to ensure a speedy rejection on their part of the specious misrepresentations they have been so long the victims of. Enlightenment in this direction is the proper function of the medical profession, and must necessarily precede that amendment of the law for which such pressing need exists. The means and the facilities must be a matter of discussion, and measures should be promptly taken.

NOTIFICATION OF INFECTIOUS DISEASE.

ONE of the statements which has been persistently repeated by those who advocate the forcing of the medical attendant to report his patient's disease to the sanitary authority, is that the anticipated inconvenience and loss to the physician who is compelled to perform this duty is all imaginary, and that the system works with perfect smoothness, and with the cordial co-operation of the medical practitioners wherever it is in force. We never believed the statement, nor have any of the advocates of the system ever afforded us the least proof upon the subject. It now appears that in one town at least, where notification has been for five years in full work, to wit, Bolton, the relation of a considerable section of the profession to the sanitary authority is, on account of the system, one of irritation and hostility.

A meeting of the Lancashire and Cheshire branch of the British Medical Association, took place recently in that town, and at it Mr. Sergeant, the medical officer of health, read the customary sanitarian eulogy on the notification system, but his opinions were not received with the enthusiasm which the notificationists have led us to anticipate. On the contrary, there was an immediate effervescence of opposition to the system, which seems not to be the least calmed down by the five years experience of its working in Bolton. We are told by the local paper that a somewhat animated discussion arose upon the paper. Dr. Royle, of Manchester, introduced the subject, maintaining that the householder and not the medical man ought to be held responsible, in which view he was warmly supported by Dr. Smith and Dr. Court, the latter of whom declared that the medical men of Bolton were not honourably treated by the Corporation. When the clause was first inserted, it was done in an underhand manner. He had still money owing to him by the Corporation for certificates (laughter). Dr. Smith said he had money owing to him also (laughter). Why did not the Corporation, he asked, require the publicans to report each drunken man; it came to the same thing (hear, hear, and laughter). Dr. Fergus Ferguson, speaking with eighteen years' experience of the work of the Sanitary Committee, believed great good resulted from such a system of reporting, but he protested and always had protested against being asked to do a thing under the threat of a penalty. Dr. Johnson Martin, as medical officer of the Bolton Rural Sanitary Authority, thought that although there had been some unpleasantness between the Corporation and the medical men of Bolton, great good had been done by the compulsory system during the time it had been in operation. Dr. Smith proposed to move a motion adverse to that part of Dr. Sergeant's paper relating to this question, but it was stated it was not usual to have motions to essays, and the subject then dropped.

This brisk wrangle, coupled with the fact that the Bill for extending the notification system to all England, was stopped in last session by Mr. Thomassen, M.P. for Bolton, is sufficient to prove that, as regards that town, the boasted cordiality of the medical profession exists only in the imagination of sanitarians. We know now that those who have had five years' experience of the system like it all the less the more they know of it, and we suggest to the profession the unwisdom of allowing the Parliamentary

Bills Committee of the British Medical Association to put the notification halter round their neck.

AUDI ALTERAM PARTEM.

THE daily papers of Thursday last contained reports of an inquest, held the preceding day, on the body of a surgeon who had died in St. Bartholomew's Hospital under circumstances that were deemed to call for an inquiry before a coroner. Briefly the facts were stated to be as follows:—Deceased, who was a surgeon, practising in Spencer Street, Goswell Road, was taken suddenly ill a week previously, and was then attended by three practitioners for some days; his condition, however, growing worse, and danger of suffocation appearing imminent, his attendants deemed it desirable that tracheotomy should be performed for his relief, the cause of illness being put down by Dr. Casidy, one of the medical men in charge of the case, as "inflammation of the larynx." This decision having been arrived at, it seems that, for some hitherto unexplained reason, it was determined to remove the patient to St. Bartholomew's Hospital, in order that the operation should be performed; and the allegation raised against the authorities of the institution is, that through delay in admitting him into a ward, death was accelerated, this being the written opinion also of Dr. Sherrard, another gentleman in constant attendance on deceased. At the inquest Dr. Sherrard described, in an indignant manner, how, on arriving at the hospital, he and his charge were first kept waiting in a cab at the door for a quarter of an hour, and that a further period of twenty minutes elapsed before the house-physician put in an appearance, the patient being all this time in a room subject to excessive draught from doors and windows. Further, that when in the ward even, the case remained uncared for in the manner that he, Dr. Sherrard, considered to be absolutely requisite for safety. In effect, it may be said that Dr. Sherrard charges the hospital officials, beginning with the porters and ending with the resident staff, with inattention and a want of regard for the interests of his patient.

So much the public has heard; but there remains to be considered the evidence of the other side, and it need hardly be said that a different complexion is, through it, put upon the story. We are informed that the statements referring to the time occupied in admitting Mr. Booth are exaggerated, as, indeed, might be assumed from the heated manner in which the evidence was tendered; and, further, the condition of the patient on admission was such as to create serious misgiving concerning the wisdom exhibited by the medical friends of the unfortunate man. By their description he was in *in extremis*, and most certainly in no fit condition to bear the removal and exposure consequent on it under even the most favourable circumstances. Also we must perforce, ask why, knowing that the only chance left for their patient was immediate opening of the larynx, these two practitioners permitted him to run the grave risk of death occasioned by delay. Surely it was their place to give him the relief they had determined to be his only remaining hope, and not to leave it unsecured

for a moment. This omission most certainly transfers any blame attaching in the case to the shoulders of those who are first to bring the charge; and far from thinking the administration of the hospital culpable in the matter, no professional reader of the accounts given will hesitate to throw the onus on the medical men who could thus incautiously expose a patient to the danger of suffocation. Moreover, on post-mortem examination signs of extensive disease were exhibited, which had been apparently overlooked by the practitioners in charge of the case, death having resulted from double pleural effusion; it will therefore be at once seen how seriously the difficulties have been overlooked. Double pleurisy is by no means an unrecognisable complaint, or one that should escape the observation of an attendant of ordinary carefulness; and all things considered, it may well be questioned whether the stigma of disgrace has been rightly allotted by Dr. Casidy to "an institution with half a million of money."

One point this occurrence may not improperly be expected to ventilate with advantage, and that is the desirability of an improvement in the room devoted to receiving applicants for admission into St. Bartholomew's Hospital. It is certainly not adapted for the purpose; it contains too many doors, which are constantly being opened and shut, and though this will in no way relieve Drs. Casidy and Sherrard of the liability they incurred by their treatment of Mr. Booth, and cannot, for a moment, be assigned as contributing to the result, mainly brought about by that gentleman's exposure and removal and the delay thereby involved, yet some benefit may be secured by an attention to the improvements called for in the room in question.

One word of advice may be permitted here to local practitioners. Too many of these entertain the notion that they are entitled to presume on their position as medical men, and to conduct themselves within the walls of public hospitals, as they may be accustomed to do in their own surgeries. This is an error; they have no more right to bluster and command, or to forget that they are governed by the laws which regulate the conduct of gentlemen when seeking favours of other gentlemen, simply because they happen to have sympathies in common with them, than is any other applicant for hospital relief. They are members of the general public as much as any other stranger, in the eyes of the hospital; and it is only by an extension of courtesy that they are permitted privileges in right of their education. These privileges are certainly worthy of respect, and so long as they are not improperly presumed on they will be recognised. When it unfortunately happens, however, that medical men forget the respect due to themselves, it should afford them no surprise if others are equally forgetful with themselves.

THE REPRESENTATION OF IRELAND IN THE GENERAL MEDICAL COUNCIL.

THE death of Dr. McClintock has placed in the hands of Lord Spencer, as Lord President of the Privy Council, the selection of a successor to represent Her Majesty in

Ireland in that body, and we hear of his lordship being importuned to appoint a specialist in obstetrics to that office, as if it were an acknowledged right of some practitioner in that department to have the place. Against such an assumption we must earnestly protest, and we venture respectfully to suggest to the Lord President that no specialist in any department ought to have any particular claim to the position. In the first place we would remind the obstetric party who are demanding that they shall hold the patent right to a seat on the General Medical Council, that they have less special claim to represent the Crown than to occupy any other seat.

The nomination of six members was intentionally reserved to the Queen by the Act of Parliament, in order that the interests of the public and the medical profession outside the licensing bodies might have some representatives in the Medical Council, and, for this reason, it would be at variance with the intention of the Medical Act that any one shall be chosen by the Crown who is not entirely independent of teaching or licensing bodies, and entirely free from personal interest in the pushing forward of any speciality. Members who are introduced to the Council simply because they are specialists, and are bound to advance their speciality, cannot be free in their judgment and in their votes upon questions in which their department is concerned, and, therefore, are not suitable for a Crown nomination. Besides, they have the elective seats of the nineteen licensing bodies open to them, and if obstetricity is, by its importance as a part of surgery, deserving of an exclusive chair for itself at the Council table, its practitioners ought to be able, by the exercise of legitimate influence, to secure one or more of these elective seats. We do not recognise in their speciality any greater right to representation than ophthalmology possesses, and we conceive that—considering the Medical Council is now constituted also a Dental Council—the dentists have an obvious right of priority against them.

The present attempt to secure the nomination of an obstetrician is encouraged, we presume, by the fact that the last occupant of the vacant seat was a practitioner in that branch of the profession. But Dr. McClintock was much more. He was the President of the Royal College of Surgeons in Ireland, and a man of supreme qualities for a maker of medical laws. If he had been a stricture surgeon, or a skin doctor, he would have been just as eligible as he was, being a gynæcologist. We entirely approve of the view taken of the matter by the Lord Lieutenant of Ireland, Earl Cowper, who told the deputation of obstetricians who waited on him that he did not see the necessity for giving the Crown nomination to anyone because he professed a given speciality, and we hope that Earl Spencer will share this opinion, and will refuse to let Her Majesty's choice be used to strengthen the influence of any "corner" in the medical profession.

Midwifery practitioners are as good for General Medical Councillors as other people, and no better; and it seems to us that the pretensions put forward on their behalf on this occasion are somewhat self-asserting and offensive to those who do not practise their particular art.

Notes on Current Topics.

Industrial Schools.

THE termination of the inquiry concerning the management of St. Paul's Industrial School may well be regarded as satisfactory evidence of a desire, on the part of the Home Office to do all in its power to render such institutions of the utmost possible benefit to society. Undoubtedly it is essential that they shall be conducted with the utmost regard to the welfare of the inmates, to the preservation of due order among them, and to ensuring thereby that protection to society which it is the first object of Industrial Schools to provide. That none of these results can follow mal-administration on the part of governors or masters of such an institution, the recent exposures have sufficiently shown, and that there may be other cases in which similar ventilation will lead to the advancement of public interests is no improbable matter. Indeed, it is already hinted that at least one institution demands searching inquiry into its management, this time at Glasgow, where, it is alleged, the matron has been guilty of acts of cruelty that will bear comparison with those perpetrated on the unfortunate inmates of St. Paul's School. This woman is said to have caused several girls to be most severely flogged, one having been thus ill-treated and then further submitted to a spray bath for the purpose of cooling. It is, of course, possible that the story is exaggerated, but it sufficiently indicates the necessity for a careful investigation into the working of all government institutions of the kind complained of, a course of proceeding that will fittingly follow as a sequel to the action already taken by the Home Secretary.

A New Needle Holder.

DR. GEORGE JONES describes, in the *New York Medical Record*, a new needle holder which presents several features that are important improvements on the holders usually employed. The forceps is placed on the end of a tube, and the jaws are closed by a strong clip embracing them, and sliding on the tube in connection with a lever situated between two handles at the other end of the principal tube. The instrument is made in two forms, and either shape when closed can be locked by a graduated slide under contact with the thumb. It can be made in various sizes, and though originally intended for gynecological work is equally adapted for use by laryngologists and other specialists. The inventor claims for his invention a power superior to that of any other needle holder, while it is also under perfect control of the operator. It can not only be used as a needle holder, but as a holder for other instruments, and an important advantage is that it maintains a certain grip of the instrument held in its teeth. The invention is apparently a very valuable improvement in many respects.

Smoke Exhibition.

An exhibition of smoke-consuming grates, and smoke abating apparatus will be opened to the public next week, at the Agricultural Hall, Islington, by the Lord Mayor. An interesting and important display may be expected, the number of exhibits being very large.

The Surgical Society of Ireland.—Retirement of Dr. Richardson from the Secretariate.

THE first meeting of the Society will take place on Friday evening next at the Irish College of Surgeons, when Dr. Chaplin, the President of the College, will deliver the inaugural address, and the Society will afterwards proceed to the reading of papers, &c., as is usual. The opening of this session of the Society is notable in consequence of the retirement of Dr. B. W. Richardson from the office which he has so long held in connection with it. The coming or going of an honorary secretary is not often an occasion for special observation, but, in this case, this Society which ministers so effectually to the progress of surgery in Ireland loses so much by Dr. Richardson's resignation that the occurrence is of direct importance to the profession in Ireland, and of some interest to students of surgery everywhere.

Dr. Richardson accepted the secretary's post nearly a quarter of a century since, when Dr. Bellingham vacated office, and since then it is no exaggeration to say that he has been the "*Deus ex Machina*" of the Society. The admirable punctuality and business-like accuracy with which his duties were performed gave strength to the institution, which it would have lacked in other hands; and by his enthusiastic co-operation with Dr. Charles Benson, who was for many years his senior in the secretariate, the meetings of the Society were always instructive and attractive.

Naturally its Council have felt that the services of a professional lifetime deserve some other recognition from the Society than mere thanks, and they have, therefore, taken steps to enable its members to show their gratitude to Dr. Richardson by offering to him a suitable present as a memento of his connection with it. The movement has been already organised, and a circular note will be—sent to each member of the Society, to which we anticipate a cordial and liberal response, such that the Council may be in a position to give a creditable expression to the sincere feelings of regret to which Dr. Richardson's retirement has given rise.

Madness and Murder.

THE agitation in favour of reprieving the convict Lefroy is based on the assumption of hereditary madness, and the Home Secretary is to be memorialised on the subject of respite. How far the prisoner really is an irresponsible agent can, of course, be decided only on the evidence of experts; but of his previous eccentricity an amount of proof has been tendered which encourages an idea of its reality. The question how far moral insanity may be recognised and admitted to explain acts of criminal violence is one that is rapidly assuming the importance it deserves; while, in France, it has long been held to absolve a culprit from the last dread punishment of the law. An extremely interesting article on this topic is printed in the current number of the *Journal of Psychological Medicine*, entitled "Legal Medicine in France;" and we are entitled to anticipate that the more enlightened views entertained by our neighbours in connection with crimes committed by lunatics, will, ere long obtain in England also. Lefroy's sanity may, with

justice, be fairly doubted; and this being so, humanity calls less for the exaction of a death penalty than for his being remitted to the care of those entrusted with the treatment of insane offenders against the laws. Up to the present we are without the data to be afforded only by actual examination of the prisoner; but this will probably be immediately forthcoming, and will offer a more reliable basis for forming a judgment on the question at issue.

A Scientific Cabinet Minister.

THE new French Ministry numbers amongst its members at least one scientifically-educated and interested individual; and very fittingly he holds the post of minister of public instruction. We refer, of course, to M. Paul Bert, the eminent professor of physiology at the Sorbonne, who has again and again lately shown his entire sympathy with the party of scientific progress, as well by action as by speech. That unbounded benefit will accrue from the presence of such a person in the Cabinet and from the influence of his counsel, is certain; and it is a noteworthy fact, as showing the thorough earnestness of M. Bert's devotion to science, that almost within an hour of his appointment by M. Gambetta he delivered, at the Academy, a lengthy and invaluable paper on "Chloroform, and other Anæsthetics."

Medicine in Japan.

ACCORDING to a note contained in the current number of *Nature*, Japan possesses a total of "169 hospitals where the patients are treated on the principles of Western medicine. Thirty-five of these are private institutions, in the sense that they receive no government aid; while twelve are military or naval hospitals. Vaccination, which is compulsory, is performed *gratis* everywhere. A law prohibiting the practice of physic or surgery by any except persons holding certificates of permission has recently been passed. A large school of medicine, with German professors, has been established for the last eight or ten years in the capital." This affords another satisfactory indication of the energy with which the Japanese are conforming to the customs of more civilised countries; and in the interests of medicine it would be interesting could we obtain the vaccination statistics already compiled.

Royal University of Ireland.

THE Senate of the Royal University met on Thursday last.

The following resolution, proposed by Dr. Lyons, M.P., and seconded by Dr. Banks, was unanimously adopted:—"That the Senate desires to record its sense of the loss this University has sustained in the death of Dr. Hayden."

It was ordered that this resolution be communicated to the family of Dr. Hayden.

The statutes of the University having been finally settled, they were sealed with the common seal of the University in the presence of the Senate, and were ordered to be transmitted to the Lord Lieutenant in order to obtain the approval of her Majesty, to be signified under the sign manual.

The Senate had under consideration the arrangements

to be made for carrying on the matriculation examination on December 6th prox., and appointed the examiners, among others those in experimental physics—George Coffey, Esq., B.A.; John England, Esq., M.A.; Joseph D. Everett, Esq., D.C.L.

These appointments have been made for the purpose of carrying on the approaching Matriculation Examination only, and confer no right to any future appointment in the University.

More Anti-Vivisection.

A MELANCHOLY meeting of about seventy or eighty persons interested in the total extinction of science was held on Monday afternoon, at Willis's Rooms, London. This gathering, convened for the "discussion" of the vivisection question, was addressed by Mr. G. R. Jones, Dr. de Noe Walker, and one or two other sympathisers with their well-known views. A single speaker who addressed the meeting on the other side so bothered the partisans of sentimentalism that they speedily thereafter dissolved the assembly, which was as convincing as any previous demonstration under similar auspices of the cant and one-sidedness of anti-vivisection principles.

Deaths of Indian Medical Officers.

THE death is announced at Delhi of Surgeon-Major Adam Taylor, Bengal Medical Service, on Oct. 24th, from an attack of measles. Dr. Taylor entered the Indian Army in 1857, and had lately been appointed Civil Surgeon and Superintendent of the gaol at Delhi. The death of Surgeon A. F. Adams, occurred at Kurrachee on Oct. 17th. He was for many years Civil Surgeon of Shirkarpur. The Madras papers also record the death of Surgeon-Major E. Trenmill, attached to the 39th Madras Native Infantry, on Oct. 25th, from disease of the kidneys.

The Census in France.

THE next census in France is to be taken before the end of the present year, and, for the first time, is to be got through in a single day. It is intended to show sex, age, birthplace, nationality, status (whether married, etc.) and occupation. The intention now expressed is to fix the next census for the year 1885, on the ground that most countries take the census in years ending with 5. Hitherto the forms have been filled in by municipal officers, who have been allowed a margin of several weeks, but forms are now to be delivered to the heads of families a few days before the date of the census.

Donations to English Medical Charities.

THE London Hospital, the German Hospital, Dalston, St. George's, and the Hospital for Consumption, Victoria Park, become entitled each to £2,000 under the will of the late Mr. M. F. Bruxner. The late Mr. James Lark, of Newlands, bequeathed £1,000 to the Kent and Canterbury Hospital. By the will of the late Mr. Horatio Bobb, formerly of Mamhead, Devon, St. Mary's Hospital becomes entitled to £100.

By latest telegrams, the cholera epidemic among the Mecca pilgrims is decreasing.

Queen's University Students in the Royal University.

THE Senate, at its meeting held last week, passed the following resolution:—"All students of the Queen's University, at the time of its dissolution, shall be entitled to present themselves for examination only to the Royal University, in the respective faculties, according to their status in the Queen's University, and in the subjects prescribed by the curriculum of that university, and according to the regulations in force at the time of its dissolution, provided that they shall not be entitled to the honours, exhibitions, or prizes maintained by the funds of the Royal University. This provision shall extend to all matriculated students of the Royal University."

The Indian Medical Service.

THE *Indian Medical Gazette* says that a rumour has got about that competition is no longer to constitute the portal to the Indian Medical Service, but that a certain number of nominations will be placed at the disposition of the principal medical schools. The native papers have it that the reason of this is that so many natives have obtained entrance into the Service, and that the authorities are afraid that the European candidates will not be able to hold their own against Indian competitors! We don't believe in the existence of any such motive, but we know well that abolition of competition means a return to nepotism and the appointment of people who have influential friends, but one too stupid to obtain appointment by work or brains. Why should the British soldier be condemned to suffer under such patronage nominee, and why should not a native Indian win his medical spurs if he can?

The Sunderland Conspiracy Case against a Medical Man.

THIS case being still *sub judice* we, as is our rule, refrain from commenting upon it, save so far having carefully read over the reports of the evidence yet adduced in support of the charge of conspiring, we cannot fail to have observed that several of the witnesses examined are, on their own confession, either what are called jail-birds, prizefighters, or the wives and daughters of the same. Moreover, it is an undeniable fact that these same persons went to Newcastle Assizes in July last prepared to perjure themselves—that is, swear to the truth of what they now swear to be false; and apparently for no better reason than that of having failed to squeeze out of their injured friends as much money as they thought they were entitled to. For a similar reason they now appear to sell themselves to the railway company, for as one of them said, "he saw others of his pals making money out of lying," and he saw no reason why he should not turn his hand to the same profitable line of business.

With regard to the medical evidence so far as it has gone, we do not see that it is likely to assist the case overmuch. A medical expert gave it as his reason for not communicating a suspicion he had formed, that the man was malingering at the time of the trial, that he had no confidence in his own knowledge of the electric test, and he had not resorted to it, nor to other equally well known tests, for, we suppose, equally good, or rather bad, reasons; and therefore he came to the conclusion

the man was a malingerer. Every opportunity had however been afforded to the company to make—not one, but three—examinations, and no impediment had at any time been placed in the way of the medical attendants in charge of the case, so that the company had the fullest opportunity of satisfying themselves as to the genuineness as to its being, as stated, a *case of concussion of the spine*. This is not denied. We shall keep our eyes open in the interest of the profession, and for the additional reason it is currently reported that the company are prepared to spend a large sum of money to secure a conviction against one who has already been a thorn in its sides.

The Hunterian Collection.

AT a quarterly meeting of the trustees of the Museum of the Royal College of Surgeons, on the 11th inst., the Right Hon. the Earl of Aberdare was unanimously elected a trustee in the vacancy occasioned by the decease of Sir Philip de Malpas Grey Egerton, Bart., who was elected in 1840 with his Grace the Duke of Devonshire and the Earl of Enniskillen.

Dublin Hospital Board.

DR. SAMUEL GORDON has been appointed to the seat on this Board, vacant by the death of Dr. M'Clintock. If the new member has any enthusiasm for official work or for hospital improvement, he will find enough left undone by the Board to occupy his energies for all the time he can afford.

The Confidences of the Physician.

EDITORS, like others mentioned in proverbs, should have good memories, for sometimes their pronouncements of last week come into a curious contrast with their opinions of to-day.

In a recent number of the *British Medical Journal* we find the following editorial advice to a correspondent who wanted to know "whether there would be any impropriety in divulging, for reward or otherwise, to a sanitary authority the existence of infectious disease in a private patient, when under no legal obligation to do so; and whether one would not be committing a breach of confidence in sending notice of disease in a private house to a public authority or anyone else."

The opinion given by the editor is as follows—

"We do not think there would be any impropriety in the medical man giving such information to the sanitary authority, but that, on the contrary, it would be a distinct gain to the public health;" and he adds the hint, "Usually, half-a-crown is paid for each such notification."

Surely, this is not the same editor who, two or three weeks previously wrote as follows—

"The duty of secrecy which is incumbent upon a medical man in respect to circumstances which have become known to him in virtue of his professional functions is regarded by medical men in all countries as involving sacred obligations, of which it is necessary to preserve the principle intact, and to defend, if necessary, even against the law itself. This obligation, like all others which an honourable profession accepts and upholds, is based upon the interests of society at large; for it is certain that if,

on the one hand, justice is concerned in acquiring the necessary knowledge for its operations, society is deeply interested in the maintenance of confidence in the medical profession, under whatever circumstances medicine is called upon to fulfil her functions."

We are charmed to find the views of our contemporary so sound on the subject of professional confidence, because it happens to be the custom of sanitarians just now to pooh-pooh the feeling of physicians on this subject as mere sentiment. This last quotation is the commentary of the editor upon the conduct of a Belgian surgeon who refused to give inculpatory evidence respecting a duel. We are dull enough not to see the distinction between such testimony and the testimony as to the disease from which a patient is suffering which the physician is to be compelled to give by the coming "notification" Bill.

The Site of the Royal Irish University.

It is reported that the Senate of the new University contemplates taking a disused skating-rink near Balls Bridge (outside Dublin), close to the suburban Cattle Show, and equi-distant from the Beggar's Bush Barracks, and the Ringsend Bottle works, with the view of placing the University Buildings thereon. The Senate might do better. If they are, as they seem, anxious to find a place out of everyone's reach, and where architectural beauty would be thrown away, we recommend the vacant ground next the manure works at Ballybough Bridge, near the Richmond Whisky Distillery, as being at once a classic and unobtrusive locality. But, surely, the report must be incorrect, for it is inconceivable that the Senate should throw its money away on a site so inconvenient and unsuitable as that which is spoken of.

Proposed Academy of Medicine for Ireland.

A PROPOSITION which has been talked about for some years, has just been revived in a more practical form, and it will shortly be brought before all the governing bodies of Medico-Chirurgical Societies in Dublin for their approval. It is proposed to amalgamate the Pathological, Surgical, Medical, and Obstetrical societies into one institution of the nature of an "Academy of Medicine," such as flourishes in Paris, the individuality of each of the constituent societies being maintained by giving to each of them a special section in the "Academy." The advantages claimed for the proposed incorporation are that while the subscriptions would not be more than the aggregate of all existing subscriptions, the work of the society would be done more effectually, and the audiences would be larger, while the publication of their transactions would be effected under very favourable circumstances, and in a form creditable to the Irish School of Medicine and Surgery. It is suggested, if this arrangement were generally approved, that the Colleges of Physicians and Surgeons and the University should be asked to allow the "Academy" to meet each year in turn within their walls.

The scheme certainly has the elements of success, and merits approval as an effort to reorganise and improve the existing means for interchange of medical thought in Ireland. The arrangements for establishment of such an institution will necessarily be troublesome, but the purpose in view is worthy the effort, and we hope the proposal will be at least pushed forward for further consideration by the societies.

The Overplus in the Profession.

THAT the profession at home is overloaded is increasingly evident from the number who openly advertise medicine and advice at sums varying from threepence to one shilling per week, still further is this impressed upon us by the number of applications we receive for information as to appointments and openings abroad. Of the former numberless instances are probably cropping up before the notice of most of our readers, and of the latter the following will suffice to illustrate our point. About a month since an appointment of medical officer to the Wynnad mining district was advertised in our columns, at a salary of £700 per annum—not a very lucrative post for India; yet seventy candidates applied, and were ready to risk the unhealthy climate of that locality for this emolument. For the consolation and information of the unsuccessful sixty-nine we may mention that, from these, five who had had considerable Indian experience were selected to meet the Board, and from these Dr. Mountain was finally appointed, and will at once proceed to take medical charge.

The population both fixed and floating of this district of Southern India has enormously increased during the past twelve months, and the health of so large and growing a community has hitherto been under the sole charge of a government apothecary, who though he has done his best during the past unusually sickly monsoon has proved totally unable to deal with any but the simplest cases. No doubt the Government of Madras, if appealed to would probably have appointed an efficient officer, but this step was not taken, and as the mining companies of the district felt that a serious responsibility rested upon them to provide the best possible advice and accommodation for their employes, eight of the leading gold mining company's associated themselves together and formed a medical board consisting of one director from each company to ensure prompt and efficient action in this important matter. An hospital will be erected, and it is hoped that a considerable decrease of sickness will be reported next season.

The General Medical Council and the Royal Commission.

WE stated last week, and we believe, truly, that the Report of the Commission was being put together. When fully drafted it will, of course, require the revision of the Commission at one or more special sittings, and it will probably not be made public until after Parliament meets in February. We think it time to ask whether the General Medical Council is to have anything to say to the subjects of the Report before it is finally approved. The Colleges of Surgeons of Ireland and Edinburgh, and other licensing bodies have recently been inspected by the Council's visitors, and it would be of great importance that the Royal Commission and the public should know what verdict has been passed on the examinations of these bodies. If the decision is favourable, these bodies ought to have the credit of the judgment when they are on trial before the House of Commons, if unfavourable, Parliament ought to know of it in order that reform may be decreed. But, if the Medical Council sleeps, as it is wont, until the dog days, these visitation reports will not see the light until special interest in them is past, perhaps not until the inspected bodies have been sum-

marily dealt with by Parliament, There seems to us good reason for a short Christmas sitting of the Council to receive these reports, and we hope the suggestion will be considered by the President.

A FIRE broke out in the Nottingham General Hospital last Wednesday night, but fortunately did but little damage.

By command of Her Majesty the Queen, a valuable present of old linen has been presented to St. George's Hospital for the use of the patients.

SIR HUGH OWEN, whose name will be remembered as Secretary to the Local Government during the passage of the Public Health Act, died at Nice on Saturday last, after only a few days illness.

THE Governors of the Glamorgan and Monmouth Infirmary have resolved to proceed at once with the erection of a new building, which is to cost £23,000. The site of the building is the gift of the Marquess of Bute.

SPEAKING at a meeting at the Royal Albert Hospital, Plymouth, Sir Massey Lopes said his duties when at the Admiralty brought him into possession of certain information as to the working of the Contagious Diseases Act. The measure appeared to have operated most beneficially, and a large proportion of the unfortunates affected by it had been reclaimed.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 25, Bombay 27, Madras 30, Paris 27, Geneva 20, Amsterdam 22, Rotterdam 21, The Hague 24, Copenhagen 21, Stockholm 18, Christiania 14, St. Petersburg 38, Berlin 23, Hamburg 21, Dresden 20, Breslau 25, Munich 30, Vienna 24, Prague 27, Buda-Pesth 28, Naples 28, Turin 20, Venice 23, Alexandria 44, New York 30, Brooklyn 26, Philadelphia 20, and Baltimore 28. No returns were received from Brussels and Rome.

THE APPARENT REDUCTION OF THE DUBLIN DEATH-RATE.

WITHOUT at all desiring to minimise the effect of the sanitary work carried out in Dublin by Dr. Cameron, it is right that we should guard against a too rosy hue being given to the current mortality by a comparison of past months. It is true that the decrease of deaths has been remarkable and gratifying, but that such decrease is not the result, exclusively, of improved sanitation is shown by the fact that the health-wave which has produced these results in Dublin has extended to the provinces where no sanitation has been attempted. The death-rate of last quarter for all Ireland is 0.9 per 1,000 of the population under the five year average, and the Registrar-General says that "the deaths were below average in all counties," and this decrease has saved 3,400 lives within the quarter. On the whole the death-rate, not of Dublin exclusively, but of all Ireland, is lower than in any year since 1876.

RE-APPOINTMENT AFTER DISMISSAL UNDER SEALED ORDER.

IN connection with the recent dismissal of Dr. Kenny, Medical Officer to the North Dublin Union, we stated, as to the possibility of his restoration to office, that we had never heard of a case in which an officer dismissed by sealed order had been re-instated. A correspondent supplies us with one such case which occurred in 1863, and does not seem open to question. We are much obliged for the correction, but it seems that this case is the exception which proves the rule.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE RELIGIOUS EDUCATION OF STUDENTS.—The students in Edinburgh are going through a process of religious patronage which will soon become a daily martyrdom. Every denomination is instituting services for the hapless youths where everything is taught but the duty they owe to humanity. Mr. Moody is to take them in hand next week. If half as much interest were taken in finding these young men healthy amusements, in a town where the dearth of such is appalling, as is taken in these so-called religious instructions there would be far fewer "chronics" and wasted lives than there are now.

A VALUABLE APPOINTMENT.—The Aberdeen Town Council are in want of an assistant sanitary inspector. The salary attached to the office is between £50 and £60 with the use of a house, (rent free) at the Epidemic Hospital. The applicants have to be married men without family, and we suppose, without hopes of such. The wife of the person to be appointed, is to act as matron of the hospital, without additional remuneration. It is to be hoped that the selected candidates have gone through a full academic course, and be thoroughly *au fait* with the nature of zymotic diseases, for it would surely grieve the liberal spirits of the Town Council to pay for additional help during the illness of the inspector or matron. All the Aberdeen sanitary officers appear to be lodged in the Epidemic Hospital.

POLICE SURGERY IN EDINBURGH.—It appears that the amount of work at the police office is so large, that surgical operations are frequently handed over to members of the "force." One woman, we learn, was so treated for a cut on her head, the amateur surgeon sewing up the wound "quite glove-like." It appears as the missionaries say, "the harvest is plentiful, but the labourers are few."

DEATH OF DR. ROBERTSON, OF HOPEWELL.—Dr. Andrew Robertson, of Hopewell, who for many years acted as Commissioner to Her Majesty and the Prince of Wales on their Balmoral and Abergeldie estates, died at Aberdeen, on the 16th inst. The deceased gentleman who had attained to the ripe age of eighty-two, was born in Perth, took the License of the Royal College of Surgeons of Edinburgh in 1818, and graduated at Aberdeen in 1858. He was thus a long time settled in the Upper Deeside district. When the Queen became proprietrix of Balmoral, Dr. Robertson was selected as Commissioner on the estate, and continued in that office until a short time ago, when he resigned on account of advancing years, Dr. Profeit being his successor. Dr. Robertson was a general favourite of the Court at Balmoral, and Her Majesty was a frequent visitor at Hopewell, both before and after he was Commissioner on the Royal estates. As a private gentleman he was greatly respected and esteemed, and his death will be universally regretted.

CHAIR OF NATURAL HISTORY IN THE UNIVERSITY OF EDINBURGH.—We hope there is no rumour for the report that certain manoeuvring is being indulged in to lessen the chances of Dr. Alleyne Nicholson's succession to this chair. Edinburgh cannot well afford to treat more of her distinguished graduates in the shabby and unjust manner which she has recently betrayed.

GLASGOW UNIVERSITY, BOTANY CLASS.—Messrs. Maclure and Macdonald, of Glasgow, have just executed a gold medal, which is to form one of the prizes in connection with the botany class of the University of Glasgow. The medal is presented by Dr. Balfour, formerly professor of botany in Edinburgh, and whose son is professor of the same useless subject, medically speaking, in Glasgow.

ABERDEEN UNIVERSITY RECTORIAL ELECTION.—As mentioned in our last, Dr. Bain, formerly professor of logic and rhetoric in the University, was elected on the 12th inst. to the office of Lord Rector of the University. The clerical and educational element strongly opposed Dr. Bain, owing to advanced and sensible opinions which he holds subversive of their authority. For Dr. Bain there were 444 votes, and for Sir James Paget 239. After the declaration of the poll, the victorious Bainites walked in procession to Dr. Bain's house at Ferryhill, where they announced the result to the successful candidate, amid protracted cheering. Dr. Bain made a short speech in reply thanking them for the honour that had been conferred upon him, and mentioning incidentally that many of his old pupils and friends had proposed to honour him with a commemorative portrait on the walls of the University. Professor Minto also spoke. The minority have lodged a protest against the election of Dr. Bain on the ground that he is an Emeritus professor, and draws a salary from the University funds.

MUNICIPAL REQUESTS TO THE PAISLEY INFIRMARY.—The trustees of the late Mr. James Clark, senior partner of the firm of Messrs. Clark & Co., Anchor Threadworks, Paisley, have just paid over to the treasurer of the Paisley Infirmary the sum of £6,000, bequeathed to that institution by Mr. Clark. £1,000 of the sum is to be added to the endowed funds of the Infirmary, and the other £5,000 is left to aid out-door patients affected by consumption. The treasurer has also received a sum of £900—being £1,000, less legacy-duty—bequeathed to the institution by the late Miss Jessie Gordon, of Helensburg.

EDINBURGH HEALTH LECTURES.—The first of the present winter series was delivered to a full audience by Councillor James Russell, M.B., on Saturday last; the subject selected being "Some Lessons from Modern Medicine." The lecturer dwelt on some of the recent advances in modern medicine and showed their relation to improved sanitary conditions, paying a just tribute of respect to the recent investigations of M. Pasteur.

FOULIS MEMORIAL.—Steps are being taken by an influential section of the medical profession in Glasgow, to raise a memorial to the memory of the late Dr. David Foulis. If a sufficient sum of money can be obtained, it has been thought that the foundation of a Travelling Fellowship in Pathology, open to all students of the Glasgow medical schools, would be a suitable form for the proposed memorial. The Fellowship is to amount to £50, annually, biennially, or triennially, according to circumstances. If the perpetuation of one's memory in this manner is at all desirable, there are few whose memories present greater claims than those of the deceased, and regretted gentleman in question. We wish, therefore, not to be misunderstood, when we say that there is usually an exuberance of emotion in connection with these movements,

and many will now come forward to perpetuate a memory, who would do very little for the bearer of it when in life. "Memoria bene reddita vitæ sempiterna." We have none but good wishes for the movement.

EDINBURGH PHARMACEUTICAL SOCIETY.—At the first meeting of the present Session of the North British Branch of the Pharmaceutical Society held in Edinburgh, on the 16th inst., Mr. Hugh MacCallum, of the Hong-Kong Government Civil Hospital, read a very interesting paper on the Chinese habit of opium smoking. Mr. MacCallum does not think the habit as injurious as it is represented to be. The Scotch clergy are disturbed on the matter, and have been in communication with Lord Granville. Would that the Scotch clergy would pay more attention to home vice, and trouble themselves less about what they know nothing of, and are perfectly impotent to influence.

Correspondence.

"DESPAIR."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your judicious and necessary article (Nov. 9th) on Mr. Tennyson's much to be deplored contribution to the current number of the *Nineteenth Century*, has recalled to my mind some verses, dealing also with "Despair," which I read in a Scotch newspaper a few weeks ago. These verses are from the pen of the Rev. Walter Smith, the author of *Olrig Grange*, a poet of no small repute, and while representing the same emotional phase with the Laureate's more studied lines, they strike a very different and much healthier note. The speaker in Mr. Walter Smith's poem is not a weak-minded egotist madly dashing himself against the bars of the cage of misery which he has laboriously constructed for himself, but a strong, kindly, faithful man, momentarily overwhelmed and crushed by a terrible and inscrutable visitation. "A Cry from the Merse," for that is the title of Mr. Walter Smith's verses, is a natural expression of the agonised grief of the relations of those poor sailors who perished suddenly in sight of their own homes during the late terrific gale on the East coast. The singer, standing in one of the fishing villages that was desolated, describes the universal bereavement, the broken hearts, the falling tears, the hearts at every door, the corpse in every home, and the extraordinary radiation and reverberation of grief in a little community, where all are "sib" or related to each other. He then goes on to indicate his own more personal share in the general calamity; how his brother-in-law has perished, and also his daughter's husband, and him who should have been the husband of his much loved Elsie. Little wonder that in such sad plight he should burst forth

"Lord God, what does it mean!
They were a' brave lads and true;
What can this misery bring
O' profit to us or to you?
My head gangs roon' when I think
How the sea lay calm in the bay,
Till it had them a' well in its grip,
And took the brave lads for a prey."

"Lord keep me frae sin, if ye can;
I canna be sure what I do;
There Elsie sits dazed-like and dumb,
And Janet moans a' the day through.
I try to keep hands o' thee Lord,
But a' that I get for my pains
Is to drift farther into the mist,
'Mid the wail o' the woman and weans."

This is natural despair born of tender affection and blinding sorrow, and not monstrous pessimism, the offspring of conceit and self-indulgence. The "Cry from the Merse," strikes a cord in every human heart, and does not require a course of Contium for its appreciation. It is an agonised cry; but no one hearing it can doubt that the trouble and sorrow are but for a season, and that hope will dawn ere long, and resignation come.

Surely, our Poet Laureate has lost his cunning, and has laid aside his inspiration, when he took up anti-vivisection. Some

decadence was inevitable when he turned from the sweetness and light of Euterpe and Erato and Polyinnia, to what Mr. Ruskin has called, "the sounding brass and tinkling cymbal" of our modern shrieking sisterhood. But we scarcely expected to find the author of "Ulysses" and "Locksley Hall" in the very slums of despair. Is it for demoralising stuff like this that the nation pays Mr. Tennyson £127 per annum as Laureate, and £200 per annum from the Civil Pension Fund? Perhaps he will favour us with an ode on Professor Ferrier's appearance at the dock of the Bow Street Police Office, a scene to which our descendants will certainly look back with feelings of anything but indifference.

I am, sir, yours, &c.,

MANDRAGORA, M.D.

November 15, 1881.

"FAIR" AND "FREE" TRADE IN SCIENCE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—All medical students must feel indebted to you for the able *exposé* of their grievances contained in your impression of last week. I desire, however, to point out to you that your comparison columns are not quite accurate, as that, for the present time, makes the case even less iniquitous than it really is. Your kind insertion of this letter will correct this charitable error. Take one or two instances of great hardship, as compared with some time ago, the professor of surgery, at the University of Glasgow, takes about £10 10s. out of each student instead of £3 8s. For the Session 1881-82 he professes to overtake the following in the field of surgery:—

1. Surgical affections of the neck.
2. Hernia.
3. External injury.
4. Syphilis.
5. Tumours.
6. Injuries of the skull.
7. Diseases of blood vessels (aneurism).

The statutory course consists of 100 lectures; thus, in round numbers, 14 lectures are devoted to each of the above subjects! Surely there is something far wrong here. At the commencement of his course, he devotes about one week's lecturing to "the history of medicine." He does not say exactly whether Hippocrates wore a swallow-tail coat, parted his hair in the centre, or went to church, but assuredly we are treated to a great deal that is silly and irrelevant. If the student wishes to learn something about the history of surgery, there are plenty of books where, at his leisure, he can obtain this information. Of course I may be informed that it is not necessary to fee the course for a second time. All I can say to this is that I should consider myself ill-equipped for practice by listening to the mere course of lectures above indicated. The professor of medical jurisprudence has found out that he can compress his course into three months, the *class-fee remaining the same*. Could the professor of surgery not accomplish some such reduction under the same conditions?

The class of *practical materia medica* was taught by a druggist. For this class £3 3s. were charged; charged for learning what? to dispense medicines; a thing which no one is allowed to do if he aspires to the Fellowship of one of the Bodies. Thanking you for your article,

I am, &c.,

Glasgow.

A MEDICAL STUDENT.

Medical News.

Royal Colleges of Physicians and Surgeons, Edinburgh.—DOUBLE QUALIFICATION.—The following gentlemen passed their first professional examination during the October sittings of the Examiners:—

Ernest Herbert Schäfer, Middlesex; John Gormley, County Roscommon; Theodore Mäller Kendall, Sydney, N.S.W.; Thomas Sharples, Preston; Searle Montith Howard, London; Alexander Wilson McFadyen, Stirling; Francis Gurney Mason, Newark; William Stephen Johns, Norfolk; Eustace Julian D'Grigny, India; Odoardo Tamasso Achille Villani Van Vestrant, London; Edmund Eyre, Limerick; James Maher, Ballinacree; John Gower O'Neill, Hastings; Robert Carrie, County Antrim; Edmond Walsh, County Cork; Alfred Ellisson Lancaster, Manchester; John Oldershaw, Derby; Arthur Wellesley Wales, Belfast; Frederick Cyril Joseph Capes, London; William Henry Clifton, Wiltshire.

During October and November the following gentlemen passed their final examination and were admitted L.R.C.P. Edinburgh, and L.R.C.S. Edinburgh:—

John Thomas Dickie, Edinburgh; Louis Fitz-Patrick, Dublin; Robert Andrew Stirling, Melbourne; Thomas Sharples, Preston; Henry Fimpson Wood, Melbourne; Alexander Macdonald Westwater, Edinburgh; John Busby Seymour, London; Edwin Williams Kelly, Calcutta; Robert Hall Neller, Madras; James Callaway, Gloucestershire; James McGregor, Portsmouth; Edgar Batricke Hanson, Cornwall; John Henry Whitham, Cambridge; William Henry Fretz, Colombo, Ceylon; Malcolm L. Cameron, Canada; Madabloy Sombaji Shroff, Bombay; William Gunn, Canada; Maurice Francis Jones, Bombay; John Buchan Spence, Berwickshire; Theodore Mäller Kendall, Sydney, N.S.W.; Howard Roxboro Elliot, Inverness, Ontario; James Howard Hough, Cambridge; Duocan McTavish, Canada; William Cormack, Canada; William Ebenezer Berryman, Madras; Francis William Joshua, Gloucester; Ernest Oxford Stuart, Woolwich; Alfred Llewellyn Perkins, Cwm Aman; John Trimble Elliot, County Armagh; John Mackenzie, Sutherlandshire; Harold Athelstane Baines, Melton Mowbray; John Oliver Chisholm, Jedburgh; Robert Joseph O'Farrell, Galway; Michael Augustine Lyson, Galway; Frederick Erskine Paton, Broughty Ferry; John Norman Thompson, Madras; William MacGregor, Ceylon; William Bird, Yorkshire; James Ballantine Hogg, Edinburgh; Anthony Salley, Yorkshire.

Royal College of Surgeons, Edinburgh.—The following gentlemen passed their final examination, and were admitted Licentiate of the College on 21st October last:—

George Esidow, Galston; Alexander Bruce Low, Edinburgh; Alexander Stokes, Liverpool; Rudolph John Mass, Michigan, United States; Matthew Finlayson, Alton, having likewise passed his final examination for the Diploma in Dental Surgery, was admitted L.D.S. on 20th October last.

Royal College of Surgeons of England.—The following candidates for the Diploma of M.R.C.S., having passed the required examination, were admitted Members of the College on November 14th:—

Castaneda y Triana, M.D.	Line, William Henry, M.B. Dub.
Conway, John, M.B. Glasg.	Ochiltree, E. Graham, M.B. Glas.
Fligg, William, M.B. Edin.	Richmond, James
Frye, John, L.S.A.	Riordan, Daniel, M.D. Q.U.I.
Greaves, Thomas, M.D.	Summerhill, Thomas Henry
Hurtley, William Maw, L.S.A.	Sykes, Matthew C., L.R.C.P. Lond.
Karanja, Merwanji Dhungibhai	Taylor, B. B. Archer, L.S.A.
Lewers, T. Ross, M.B. Melbourne	Vitjoen, Anthony G., M.B. Edin.

The following were admitted on Nov. 15th:—

Adeney, Edwin Leonard	Hingston, Richard, L.S.A.
Archer, Henry Edward	Marshall, J. Grissell, L.S.A.
Chittenden, Thos. Hillier	Martyn, Ernest, M.B. Aberd.
Coles, Wm. James, L.S.A.	Rayner, Hugh
Daint, Elliot	shaw, Lauriston Elgie
Evans, J. Durance, L.R.C.P. Ed.	Square, James Elliot
Gordon, Bryce	Williams, Robert
Hart, William Hamilton	

The following were admitted on Nov. 16th:—

Cleaver, William Fidler	Greenwood, George
Cowan, Richard H., L.S.A.	Harrison, James, L.R.C.P. Ed.
Bertram, Benjamin	Harvey, Kildon, L.R.C.P. Ed.
Birkett, Ernest	Husband, J. C. Radcliffe
Deane, Herbert Edwd., L.S.A.	Kershaw, Hugh
Edwards, T. B. Charles	Pitt, G. Newton
Fox, George	Style, R. George
Garrard, C. B. Orish	Thomson, Robert Blair
Gotch, Francis	Williams, H. Egerton

King and Queen's College of Physicians in Ireland.—At the usual monthly examinations for the Licenses of the College, held on November 7, 8, and 10, the following candidates passed:

For the License to practise Medicine—

Callan, Richard	McCabe, Alfred Alexander Donald
Galston, John Seymour	McCormac, William Lane
Kisby, James Henry	O'Carroll, Joseph Francis
Ledwich, Edward L'Estrange	Skerrett, Patrick de Basterot

For the License to practise Midwifery—

Galston, John Seymour	McCormack, William Lane
Kisby, James Henry	O'Carroll, Joseph Francis
Ledwich, Edward L'Estrange	Peyton, Henry Reynolds
McCabe, Alfred Alexander Donald	Skerrett, Patrick de Basterot
	Sugrue, Jeremiah

The following Licentiate were admitted Members of the College during the same examinations:—

MacDowel, Benjamin George, M.D. Dub. 1858, F.R.C.S.I. 1845, Licentiate of the College 1880.
Rae, William Masters, Surgeon R.N., Bermuda, Licentiate 1876.

NOTICES TO CORRESPONDENTS.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

ONE WHO WAS THERE, writes an account of what he heard at the police-court during the recent prosecution of Dr. Ferrier. The choicest morsels will hardly bear repeating. Needless to say they consist of decided abuse of science in particular and every branch of knowledge in general. Our correspondent will do well to avoid such recreations in future.

MR. CRISHOLME.—Thanks, the enclosure has been utilised.

MR. HARE—Communication not yet to hand, probably miscarried, or lost through the post.

HUMANITY.—Your disgusting letter is a fit indication of the loathsome condition to which systematic obstruction to the progress of knowledge reduces such as yourself. Your sickening cant about the "sanctity of animal life" is powerless to disguise the hypocritical pretence that governs your actions and affects us in no way.

CYPRUS REGENERATE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—A medical friend of mine who has been in bad health, but is now better, has read Dr. Cullen's account of Cyprus in your last issue, and has asked me to write to you to inquire (if you know) how district surrogencies in that Island are to be obtained, and, if possible, the duties and emoluments, also whether a surgeon would be able to make a living there by private practice? If you can answer any of these queries you will much oblige him and
Yours sincerely,
CHI HA ARTE PER TUTTO HA PARTE.

CHI HA ARTE PER TUTTO HA PARTE.

"* We have no personal knowledge of Cyprus, and cannot, therefore, furnish our correspondent with the desired information. We doubt not that Dr. Cullen, who kindly contributed the paper, will, as a resident in that Island, afford the information sought.—ED]

ERRATUM.—"FIRE" AND "FAIR" TRADE IN SCIENCE.—In consequence of the corrected proof of this article having miscarried, one or two trifling errors have occurred. The comparison columns of study should have been as follows:—

Curriculum of Study at Glasgow, 1862.	£ s. d.	Curriculum of Study at Glasgow, 1881.	£ s. d.
Anatomy, 1 course ..	3 3 0	Anatomy, 3 courses ..	11 11 0
Practical anatomy, 1 course ..	1 11 6	Chemistry, 2 courses ..	6 6 0
Anatomical demonstrations, 1 course ..	2 2 0	Botany, 2 courses ..	5 5 0
Chemistry, 1 course ..	3 3 0	Physiology, 2 courses ..	6 6 0

Botany, 1 course ..	3 3 0	Practical materia medica ..	3 3 0
Perpetual hospital ticket, including clinical lectures on surgery and medicine ..	10 10 0		

Total thirteen classes at a cost of .. 44 2 0 Total twenty-one classes at a cost of .. 85 1 0

DR. H. C. L.—Thanks for enclosure; will have the book looked out and sent you.

MR. P. A. W.—We do not consider yours a case which calls for commiseration. If you have made £80 in your first years' practice you have been exceedingly fortunate. We know several, now eminent medical men, who did not make so much during several years. You must have patience; the fact of achieving even this much should be an incentive to go on, although we admit it is impossible to live upon such a pittance if you have no private resources.

H. C. B.—If possible in an early number.

ANTI—You might have signed yourself anti—everything which has for its object the public good. Both Prof. Ferrier and we can stand your anonymous attacks with equanimity.

THE CLINICAL SOCIETY OF LONDON.—A CORRECTION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In your report of my paper on "The Removal of a Pebble by Tracheotomy from the Right Bronchus" the compositor has by some accident substituted St. George's Hospital for Guy's Hospital.

I would not have troubled you to correct this trivial error but that, viewed in connection with the nursing dispute which so disquieted us last year, it might convey to some the impression that I had separated myself from my Alma Mater.

I am, Sir, your obedient servant,

B. CLEMENT LUCAS, B.S. Lond., F.R.C.S.,
Senior Assistant Surgeon to Guy's Hospital.

18 Finsbury Square, E.C.

MR. WILSON.—Your distinguished namesake has received the honour of knighthood, and your surmise is, therefore, entirely justified by the result. The intention was frustrated without any interference from us.

DR. J. H. B. will find the subject referred to in another column.

DR. DAVEY.—The case was reported in a medical contemporary, and excited a considerable amount of attention at the time. Subsequently several suggestions were made for the removal of the bottle, and among them the plan proposed by you had a place. It is impossible to say what success would have attended it, but we think that when the Vivisection Act is repealed experiments to determine the point will be advisable.

SCUTATOR.—Not suitable for our columns, thanks nevertheless.

J. O. F.—The proceedings of the late International Congress will form the contents of special volumes which are now in course of preparation, and the issue of which must necessarily depend on the rapidity exhibited by the compilers entrusted with the work; they will be a most valuable memorial.

THE SOCIETIES.

HUNTERIAN SOCIETY.—This (Wednesday) evening, at 8 o'clock, Dr. Farl, "On some Cases of Hydatid Tumour of the Liver."

QUEKETT MICROSCOPICAL CLUB.—Friday, Nov. 25th, at 8 p.m., Mr. W. H. Gilbert, "On the Structure and Division of the Vegetable Cell."

CLINICAL SOCIETY OF LONDON.—Friday, Nov. 25th, at 8.30 p.m., Dr. Mahomed and Mr. Cripps, "On Two Cases of Direct Transfusion of Blood from Haemorrhage in Typhoid Fever."—Dr. Whitlam, "On Three Cases of Continued Fever with Affection of the Spleen and unusually High Temperatures."—Mr. W. H. Bennett, "On a Case of Talipes Equino-Varus treated by Resection of a Portion of the Tarsus" (the patient will be exhibited).—Mr. J. K. Lunn, "On Two Cases of Myxodema, male and female" (the patients will be exhibited).

SURGICAL SOCIETY OF IRELAND.—The Inaugural Meeting of the Session will be held on Friday evening, Nov. 25th, at 8.30 o'clock.

HARVEIAN SOCIETY OF LONDON.—Thursday, Dec. 1st, at 8.30 p.m., 1st Harveian Lecture by Dr. Alfred Meadows, "Menstruation and its Derangements." (The second and third lectures will be delivered on Dec. 8th and 15th.)

Appointments.

- COOPER, E. F., L.R.C.P.L., M.R.C.S.,** Assistant Medical Officer to St. Andrew's Hospital for Mental Diseases, Northampton.
- FOX, F. C., B.A., M.B., M.R.C.S.,** Physician to the North West London Hospital.
- GOFTON, J. E., L.R.C.P. Lond., M.R.C.S.,** Medical Officer for the North Shields District of the Tyne-mouth Union.
- GOULD, A. P., M.S. Lond., F.R.C.S. Eng.,** Surgeon to the North West London Hospital.
- LANGTON, H., M.R.C.S.E.,** District Medical Officer to the Brighton and Hove Dispensary.
- MARR, L. P., L.R.C.P. Lond., M.R.C.S.,** House Surgeon to the Richmond Hospital, Surrey.
- OSBORNE, H. E., M.R.C.S.,** Assistant House Surgeon to the Infirmary for Children, Liverpool.
- OSWALD, J. W. J., M.D. St. And., F.R.C.S.,** Medical Officer for the Third District of the Parish of St. Mary, Lambeth.
- POWELL, G. B., L.R.C.P. Ed., L.R.C.S. Ed.,** Public Vaccinator to No. 2 District of the Nottingham Union.
- REDMOND, J. M., M.D., M. & L.K.Q.C.P.I.,** Physician to the Mater Misericordiae Hospital, Dublin.
- EKKNIE, F., M.B., C.M. Ed.,** Medical Officer for the Whitley District of the Tyne-mouth Union.
- RICHARDSON, C. B., M.B., M.R.C.S.E.,** Senior House Surgeon to the Brighton and Hove Dispensary.
- TELFORD, A. B., M.D. Glas., L.R.C.S. Ed.,** Medical Officer for the Pilkington District of the Bury Union.
- THELWALL, L., L.R.C.P. Ed., L.R.C.S. Ed.,** Medical Officer for the Stillton District of the Peterborough Union.

Births.

- BELLAMY**—Nov. 16, at 17 Wimpole Street, London, the wife of Edward Bellamy, F.R.C.S., of a daughter.
- WOOD.**—Nov. 17, at Gosport, the wife of Staff-Surgeon J. Wood, M.D., B.N., H.M.S. Duke of Wellington, of a daughter.

Marriages.

- KENNY—M'GRATH.**—Nov. 8, Michael J. Kenny, L.R.C.S.I., Lismore, to Kate, daughter of the late John M'Grath, Esq.
- WATSON—BLANSONE.**—Nov. 15, at Mount Kisco, New York, Barclay S. Watson, M.D., of Iowa, to Ada, daughter of the late Dr. S. Ransom, of Wandsworth Common. (By telegram)

Deaths.

- BATEMAN.**—Nov. 21, at his residence, Canonbury, N., Henry Bateman, F.R.C.S. Eng., aged 74.
- BUCKNILL.**—Nov. 12, at Rugby, Samuel Birch Bucknill, M.D., aged 65.
- CAMDEN.**—Nov. 15, at 18 West Parade, Rhyll, Sarah Camden, for 50 years the beloved wife of G. J. S. Camden, M.R.C.S., aged 81.
- GORE.**—Nov. 14, at Bath, Richard Thomas Gore, F.R.C.S., in his 83rd year.
- OLDFIELD.**—Oct. 17, at Surinam, West Indies, Edmund Oldfield, M.D., late of Aahill, Norfolk, in his 49th year of his age.
- SCOTT.**—Nov. 17, at Lancaster House, Lincoln, William Edward Scott, M.R.C.P., aged 30.
- VARLEY.**—Nov. 13, at Burton Street, Nottingham, John Varley, L.S.A. Lond., aged 67.
- WILSON.**—Nov. 19, at Alnwick, Northumberland, Robert Wilson, M.D., M.R.C.S., Surgeon-Major, aged 52.

CLINICAL LECTURES ON SYMPTOMS.

Delivered in the Wards of the Hospital.

By **FREDERICK T. ROBERTS, M.D., B.Sc., F.R.C.P.**, Professor of Materia Medica and Therapeutics at University College; Physician and Professor of Clinical Medicine at University College Hospital, &c.

LECTURE I.

GENTLEMEN,—If you desire really to learn medicine, and to become competent practitioners in this department of your profession, you must make up your minds to study the subject systematically and progressively, and must be prepared to give your intelligent and close attention to what may often seem to you to be tedious and uninteresting details. Your object in coming to these wards is, or ought to be, to lay a good foundation, broad, sound, and firm, upon which you may build in the future. You may now acquire useful knowledge, and learn many facts which it is essential you should be acquainted with; you may familiarise yourselves with the clinical examination, and to some extent with the management and treatment of patients; you may gain practical skill in carrying out the different modes to this clinical examination, some of them difficult and needing much patience, and at the same time learn the meaning of the phenomena thus elicited; and you may train yourselves in clinical observation, in careful and systematic case-taking, and in that mental process by which the diagnosis of a patient's disease is arrived at. Do not imagine that while students you can acquire all that you need for practice. Some students soon arrive at the opinion that they know everything, but they do not, and a very short experience of actual practice on their own responsibility will convince them of this, if they are not incorrigibly conceited.

I have on a former occasion given you an outline of how to "take a case," and I then pointed out that one of the most important parts of this process consists in finding out

what symptoms are present. I take it for granted that it is unnecessary for me to define the meaning of the word "symptom," and my first duty is to impress upon you that you have no right to be satisfied with merely ascertaining the chief symptoms which are present in any case, and then proceeding to treat these without troubling to investigate further, or to trace them to the morbid condition or conditions upon which they depend. This is what is often done, not uncommonly to the serious injury of the patient. Of course, I do not imply that symptoms must never be treated, but they should not be treated as a rule until their meaning in the particular case is understood, and their relations duly recognised; it will then frequently be found that they need not be specially interfered with. Your clear duty is to fathom to the best of your ability the whole case, when a patient comes under your care. It may not even be sufficient to discover one *disease*, for very frequently, as is exemplified in these wards at the present time, there are combinations of diseases in the same or in different organs or structures, each of which may contribute to the causation of the symptoms, and may demand recognition. Symptoms must only be regarded as one class of phenomena by which we are helped and directed in our endeavour to attain the end which I have indicated. Even when they are in a sense *diseases*, it is requisite to try to trace them to their ultimate source. For instance, we have at present in these wards some cases in which there is ascites or dropsy of the peritoneum; this is obviously in itself a diseased condition, nevertheless we are not justified in regarding it independently, but must seek to find out the precise seat and nature of the disease upon which this local dropsy depends, before we have any right to take measures for its treatment. I must qualify these remarks by stating that if a symptom is urgent, or if the investigation of its cause is likely to injure the patient, our duty is often to treat such symptom at once, and wait for a more favourable opportunity for further inquiry. Thus, we have recently had a case of severe hæmoptysis in the wards, which ultimately proved fatal, and you will remember that I refrained from disturbing the patient myself, and forbade any examination of his chest. Our duty

in this case was clearly to endeavour to stop the bleeding, and not to endanger the life of the patient by seeking to find out precisely what it depended upon, or searching for its exact cause, especially as we had sufficient evidence to show that he was suffering from phthisis.

In the next place let me remind you that it is not sufficient to learn by rote, and to be able to repeat in parrot-like fashion, the symptoms belonging to each particular disease to which the body or its various parts are liable. I might take several diseases of an organ, and enumerate precisely the same symptoms as belonging to each one of these diseases; and, indeed, two or more organs may present certain symptoms of a similar character; while very different cases may have exactly the same symptoms. Therefore it is necessary to *understand* symptoms, not only in themselves, but also in relation to particular organs and diseases, and in individual cases. This brings me to the object of these lectures or demonstrations, which is to *study* symptoms with you, and, so far as opportunities permit, to study them as they are exemplified in cases in these wards, so that thus we may come to comprehend them more fully in all their relationships. I propose to carry out this object according to the following plan:—1. To offer a few observations respecting symptoms in general. 2. To discuss the symptoms belonging to particular systems, organs, or structures. 3. To consider the combinations of symptoms in individual cases, of a more or less complicated nature. 4. To study some of the most important symptoms separately and in detail, as regards their ætiology, varieties, treatment, and other points.

GENERAL OBSERVATIONS ON SYMPTOMS.

Various terms have been applied to symptoms, but I only think it necessary at present to call your special attention to the following divisions, namely, into:—1. *General* and *Local*; and, 2. *Subjective* and *Objective*. These distinctions you should always keep in mind, and probably you all know the meaning of the terms, which is obvious enough. For the sake of completeness, however, I will try to indicate their real meaning, which is not always recognised, and to offer one or two remarks relative to them. *General* symptoms usually imply that the entire system is more or less involved, and, as a rule, they are not connected with any one particular cause, nor have they a local origin of a definite kind, but may be due to many causes, and have their source in a variety of local conditions—various as to their seat and nature. Emaciation and debility will serve to illustrate these remarks. There are general symptoms, however, in so far that they affect the body extensively, or it may be throughout, which yet have a definite local origin, such as jaundice connected with the liver, general dropsy with the heart or kidneys, and general paralysis with the nerve-centres. *Local* symptoms are limited to some particular part of the body, or are evidently associated with some individual organ or structure, and have a more or less obvious local cause originating them. It is, therefore, of the utmost consequence to learn at the outset the symptoms which may be expected in connection with each system or part of a system, such as the respiratory, circulatory, or nervous; as well as with the several organs and structures of the body.

The division of symptoms in *subjective* and *objective* is also a very important one to bear in mind.

Subjective symptoms are those which are merely felt by the patient, and of which he alone is conscious, whose statement and description we have, therefore, mainly to rely upon as to their reality and characters. This group is exemplified by such phenomena as pain, tenderness, headache, nausea, general languor or debility, diminution or loss of sensation, blindness or deafness, numbness, itching, &c. Patients sometimes describe subjective feelings of the most unusual and extraordinary kind, and you must be prepared to consider these in an intelligent and sensible manner, taking them for what they are worth, but guarding against being led by them into erro-

neous conclusions. While, on the whole, we have to be satisfied with the patient's statements with regard to subjective symptoms, and, consequently, their diagnostic value is far less than that of the objective class, and we have to be very careful what importance we attach to them; yet we may be able, by careful observation of the patient, and by certain modes of investigation, to verify these statements, or to prove that they have no foundation in fact; and also to make out the degree and certain other points about subjective sensations which we can determine for ourselves, and of which, perhaps, the patient can give us no reliable information. For instance, when a patient complains of pain or tenderness, we can often test its reality and intensity, and may be able to localise its exact seat, by noticing his manner, posture, movements, expression, mode of breathing, &c.; or by watching the effects produced by acts likely to influence certain local pains, such as the effect of deep breathing or coughing upon pains in the chest, or of rising from the sitting posture upon pain in the loins. It may happen, moreover, that the patient does not spontaneously complain of any abnormal sensation; but this is only brought out by the practitioner's examination, and it may even then be of much importance. This applies particularly to tenderness which may be a symptom of considerable moment when there is no spontaneous pain. Again, by proper investigation and care, tenderness may be distinguished from mere excessive sensibility or hyperæsthesia of the skin—a point of much practical importance. It is often easy to test the reality and degree of weakness of which patients complain. Such symptoms as loss of sensation, blindness, and deafness, can also be investigated very effectually in many cases; and it is a point worthy of special notice that examination by a doctor has sometimes revealed to a patient that one of his eyes has lost its sight.

You will gather, then, from the foregoing remarks that subjective symptoms, while always being taken into due consideration, must be regarded with caution, and not have too much weight attached to them; and they should in every case be duly tested when practicable. Care is especially needed when the patient has some purpose to serve in his own interest. Apart from positive malingering you will find in many kinds of practice that people want holidays, or belong to a "club," on which they wish to be placed, or are anxious to get into a hospital for a while, and they complain of pains and various other sensations, which you, perhaps, cannot positively deny, or prove or disprove the existence of, and your discretion and judgment may be sorely taxed sometimes. But remember to be just to your patient, and cautious on his behalf, as well as in the opposite direction. I have known cases in which patients were supposed to be "shamming," and treated accordingly, because they complained of a constant localised pain for which no cause could be found, but which was afterwards accounted for by the sudden bursting of an aneurism, or the rupture of a gastric ulcer. The various strange sensations you will meet with in hysterical and hypochondriacal patients you may as a rule regard as of little or no real consequence, but these must also be duly noted and investigated.

Objective symptoms include all clinical phenomena which are either at once evident to the observer, or can be discovered by the aid of the senses of sight, hearing, touch, or smell, as these are ordinarily employed. It is expedient to place in a separate class the so-called "physical signs," which are ascertained by certain special modes of "physical examination." It will be obvious to you that objective symptoms are of far greater importance and diagnostic value than those of the subjective class. They can usually be verified without any difficulty, and it is the duty of the practitioner never to take a patient's statement as to the presence of these symptoms, but always to investigate them for himself. It is remarkable how often patients deceive themselves even about objective conditions, and innocently imagine them when they do not exist. Moreover, malingers and hysterical persons will deliberately pretend to be affected

with certain symptoms, such as paralysis, local swelling, fever, dyspnoea, or cough, the reality of which can be usually easily tested, though even here there is a danger of being misled. You probably have heard of cases in which individuals have practised deception when actually under close observation in hospital wards, by causing the temperature, as recorded by the clinical thermometer, to rise to remarkable heights. They will sometimes colour the urine and skin to simulate jaundice; produce artificial blisters on the surface of the body; feign fits or convulsive attacks; pretend to have discharges of blood, and to suffer from various other symptoms which have no actual existence. Again, it is often requisite to investigate objective symptoms, when they do exist, in order to determine their degree, localisation, characters, or other points which may be suggested in connection with particular symptoms, and in particular instances. Redness, swelling, wasting, cough, and dyspnoea will serve to illustrate this remark. It may be insisted upon as a general rule, that any unusual discharge from certain important organs should be examined by the practitioner himself, and that he should not trust to the descriptions of patients or their friends. This applies to such things as vomited matters, the stools in many cases, expectoration from the respiratory organs, discharges in the urine, hæmorrhages, and purulent discharges from various parts of the body.

The foregoing remarks will have prepared the way for indicating the modes by which symptoms are made out and studied in particular instances, and I may take this opportunity of pointing out in general terms, without entering into any details, what methods of investigation may be required in order to determine the clinical phenomena present in any given case. They may be considered under the following heads:—

1. Superficial observation.
2. Questioning.
3. Objective examination.
4. Ordinary physical, chemical, and microscopic examination.
5. Special skilled examination.

(To be continued.)

ON AIDS TO EPIDEMIOLOGICAL KNOWLEDGE. (a)

By GEORGE BUCHANAN, M.D., F.R.C.P. Lond.,
President of the Epidemiological Society; Consulting Physician
to the London Fever Hospital.

OUR Society enters to-day on the thirty-first year of its life. It has experienced its ordinary share of difficulties, and its full measure of success. In no small degree its difficulties have been the creation of its success. That greater concern is now felt about scarlatina, typhus, small-pox, &c., than at the time of the Society's creation, and that public bodies and their officers compete with us in their interest for the problems which we study, is a result to which our Society has contributed in a foremost degree, but we still continue to hold our place as pioneers. We have among us people who study the subject from different standpoints at the bedside, in the post-mortem room, or in the camp, the ship, &c., but we want for success to study the *δημος* under other aspects than the technically medical, to study other *δημοι* than our own, and to identify ourselves with statesmen, geographers, and with travellers, to obtain help from chemistry and physics, from meteorology, botany, and zoology; indeed, it would be difficult to name a department of human knowledge to which we do not hope some day to become indebted.

Our first thought is of the place we shall gratefully

assign to mathematics. So identified is epidemiology with mathematics that there has occasionally been a confusion in the popular mind, and the study of epidemics has been regarded as essentially an affair of statistics. Epidemic disease claims the aid of numbers, but it would be a serious error to think of this relation ending with records of quantity of disease, of death-rate, sickness-rate, &c. It is by arithmetical analysis of coincident circumstances of one and another sort that a clue is often got about the relation of effect to cause, as to efficiency of cause to produce effect. The case of relation between cholera and elevation of soil is an example familiar to us of an experience noted by the arithmetician to have something in it for the physician to inquire about. Of another sort of arithmetical help an evidence was afforded to me in the investigation of a fever outbreak, when, of two competing sets of circumstances, either of which might contain the cause of the outbreak, I was told the probabilities in favour of the one set were as 375 to 1, while the probabilities in favour of the other set (putting aside any probabilities against it) were but as 6 to 1. As another illustration:—An investigation is being made as to the possible influence of an infectious centre upon its neighbourhood. Putting aside influences that may destroy it, there is necessarily more of it at a spot near the centre than there is at a spot further off—that is, so long as the distribution is effected after the fashion of a something radiating from centre to circumference. The question arises: How much more infection will there be at a given nearer point, than at a given more distant point? because an answer to this question is wanted before we can go on to consider the meaning of the facts we observe. In reply to this question we shall see that the distribution of our infection will be affected according as it is effected along a single plane or into space of three dimensions. In the former case the relative amounts of infection present in two given places will be inversely as the distance of each place from the centre; in the latter they will be inversely as the squares of the distances. Now, there is reason for thinking the contagious matter is subject to the laws of gravitation, wherefore it is to the plane of the earth's surface that the contagion will tend, and its distribution in that plane will come to be effected according to the law that governs radiation in one plane. In this way we can appreciate the rate at which the spread of infection should manifest itself, and we can understand the significance of the actually observed distribution.

The best example of our indebtedness to physical science may be taken from the lessons that the physicist has taught us of the characters of infection itself. At the foundation of our Society there was but a half-formed recognition of the fact that every disease of the class with which we concern ourselves has a material of its own. The earlier addresses of our first President contain many exhortations to the use of the microscope as a means of understanding the nature of diseases which we had to study, and from the microscope in the hands of Dr. Lionel Beale we soon came to know of the existence of particulate matter in infective liquids; but it was not until the resources of the physicist had been applied to separate out the particle from the fluid that any conclusion could be formed about the inherence of the quality of contagiousness in the one or the other element of the infectious liquid. The method of diffusion was used by Chauveau to such liquids, and first to vaccine lymph: the soluble was separated from the particulate, and the potency of the lymph was found to be in the particulate only. It was soon found that other contagia, like small-pox, exhibit the same quality.

At this time the pathologist had been cautiously tracking other lines of research; and so long ago as 1841 a happy inspiration had led Dr. Farr to insist upon the use of the word "zymotic" as best expressing the character common to epidemic, endemic, and contagious diseases; and then in 1848-49, Dr. John Snow had satisfied himself that the best explanation of the phenomena of

(a) Presidential Address delivered at the opening of the Epidemiological Society for the Session 1881-82.

cholera and its spread was to be found in the existence of a specific cholera "cell," capable of passing into other bodies and producing cholera in them.

Further, Dr. Budd reached the judgment, alike for diseases propagated through air and for those communicated by water, that "the contagious agent which issues in the excreta is the fruit of its own prior reproduction within the already infected body."

In studying the nature of various fermentative and putrefactive processes, it has appeared to Professor Schroeder and M. Pasteur that certain microscopic bodies are essential to such changes. From the standpoint thus reached by the chemist, the chemist himself came to regard similar organisms as probably concerned in processes of disease also; and the researches of M. Pasteur in 1865 into the disease which was so fatal to silkworms, gave sufficient demonstration. This was a true view of the case in respect of that disease, and afforded a stronger presumption that the material of contagion was in nature a parasitic being having a life and life-history of its own. This strong presumption rapidly led to further inquiries; one after another the characteristic staff-shaped bodies of splenic fever, the spirillum of relapsing fever, and the microzymes of vaccine, of small-pox, and of sheep-pox have been made out.

For years before this period, the suggestion that particulate contagium must, almost of necessity, be *contagium vivum* had been one that had its attractions for the botanist. What if it should be the reproductive matter of some vegetable thing? At one time it did seem that we should find the genesis of cholera in that direction. It is to be admitted that Dr. Burdon Sanderson's critical examination of Professor Hallier's experiments relegated to the domain of the unproved this promising vision, but we are coming more and more to expect that the materials of some contagia have another *habitat*, perhaps in a known, but not yet recognised, alternative form. As time has gone on, and one disease after another has been found to be accompanied by organisms that are apparently concerned in their pathological processes, as the several members of the epidemic and contagious groups have been brought, with more or less of probability, into the list of those which have parasitic vegetable organisms for their actual cause, we are invited further to observe in the natural history of the various organisms affinities of botanical classes broadly corresponding to the nature of the groups of diseases with which they are found associated.

Unquestionably the prospects held out to the epidemiologist are of the most fascinating kind. As there was a period when we were promised in the behaviour of metallic oxides in the presence of peroxide of hydrogen the line of explanation of what constituted contagiousness, so now we seem to have reached a point where the botanist offers us the most promising insight into the nature of what is epidemic.

I wish to spend the time that remains to me in pointing out some of the interesting and important consequences that follow from the doctrine which would regard the material of infectious disease as something in its essence having a place and mode of life beyond the infected body. One of these is the possibility that is appearing of being able to cultivate that material outside the body in ways that shall give it different degrees of potency. So long ago as 1867, Dr. Sanderson had distinguished two sets of consequences producible by local inflammations artificially set up in the lower animals—the one a chronic disease having the characters of tubercle, the other an acute disease presenting the features of pyæmia, and both infective and being producible at the will of the experimenter by the inoculation of the same material. In 1872 he demonstrated in a number of acute infective processes, microzymes abounding in the exudation liquids and in the blood; he showed how by successive transmissions of infective material an intensely virulent material could be obtained, the original product and the cultivated material having certain microscopical and physical characters

distinguishing the one from the other. Dr. Knoch, of Wolstein, made a notable advance, and found the bacilli of splenic fever grow and multiply in blood serum or aqueous humour, and even in artificially prepared cultivating liquids, and that this could be done through successive generations, more than this, he found that mice inoculated with matter that contained numerous spores died of splenic fever in twenty-four hours, whereas mice inoculated with liquid in which spores were scarce did not die until later. And shortly afterwards our own Dr. Klein found this same property of cultivating outside the body in the very similar bacilli of the disease of the pig, known as pnenmo-enteritis, and that liquid of the eighth generation inoculated in a pig produced a disease reduced in intensity.

In 1879, Dr. Burdon Sanderson found that the cultivation of anthrax in the body of rodents modified the poison so that the subsequent inoculation of a bovine animal did not destroy the life of the latter, but protected it from subsequent attacks of disease. At the same time M. Pasteur made out for the disease called "fowl-cholera" the same quality of cultivability by multiplication of its bacilli in organic, but not vitalised, liquids.

We cannot help having before us the dazzling prospect of being able to offer to men and animals the protection of a trivial disease against each more fatal disease, to achieve what M. Pasteur calls the "vaccination" of animals against the several dangerous contagia.

But perhaps as valuable are the indications we are gaining of possible means of preventing epidemic diseases in other ways. Suggestions arise of material of contagion having, like tape-worm, an alternative mode of life outside the animal body, or in one animal body leading a different sort of existence from that in the other animal body. What if the material of cholera, or of yellow or of enteric fever, should have another *habitat* than as a contagium, and there exist, having no power of producing disease until its conditions were changed, but then altering its mode of life, and becoming the active material of disease in animals into whose bodies it was introduced? What if we could recognise it in its other fashion of life, and destroy it or prevent the conditions necessary for its development? In 1875, Dr. Klein recognised in a particle peculiar to enteric fever a microphyte, which had been identified by Professor Cohn, of Breslau, as occurring in the water of a well at Breslau, and the district of the city supplied by that well had long been famous for the amount of enteric fever in it. The relation between milk and outbreaks of enteric or scarlet fever or diphtheria has been thought of as a mere affair of disease entering milk-cans by the aid of water used in washing or of hands used in milking cows. It may turn out that the disease-producing milk has received some organism that under other conditions of life would have been impotent, or such organism have been derived from the body of the cow itself.

Indeed, the hygienist is coming to suspect that he may often have to do with organised material not far developed from perfectly non-specific germs. It is impossible not to recollect the inquiries of Dr. Ballard, of Welbeck and Nottingham, in which he heard of strange maladies occurring in groups of people, and having their cause in some common article of food.

Such are a few examples of the aid which pathology is rendering to an understanding of epidemics. It must be of concern to our Society in the future to have regard to the many new considerations that are presenting themselves to us, and to put the views of the pathologist to the test of our manifold experiences.

ACCORDING to the report of the health officer of Hastings, it appears that the mortality of that favourite watering place for the past quarter was only 13 per 1,000 of the population. A most satisfactory state of things.

THE PRACTICAL VALUE OF RECENT RESEARCH ON MICRO-ORGANISMS. (a)

By THOMAS M. DOLAN, F.R.C.S. Ed.,

Medical Officer to the Halifax (Yorkshire) Union Infirmaries.

MR. DOLAN commenced by saying there is a romance in history, in philosophy, and there is even a romance in science. We read in the early myths of different countries how fabulous knights went forth armed *cap-a-pied* to destroy the grisly monsters—dragons, centaurs, and griffins, who came down from mountain passes, or from the depths of dank morasses, and impenetrable forests, to devastate and destroy; how whole flocks of sheep and oxen were carried off; how men and women were slaughtered; how vineyards were blasted; how all life and vegetation disappeared before the flame of the breath of these mythical creations. No doubt, in early days, famine and pestilence prevailed. Man, ever eager for knowledge, was anxious to know the cause of such occurrences; in explanation teachers fell back upon the unscientific use of the imagination. In more imaginative climes, with more poetic temperaments, a belief in gods and goddesses took the place of ruder and earlier conceptions on pestilence. Thus we read in that grand work the *Iliad* of Homer, how a fatal pestilence is raging in the camp of the Greeks. What can be the cause? The soothsayers are consulted. The answer is given. The sun god is angry. Diana and Apollo are showering down their wrath in the form of the mysterious diseases which are devastating the Grecian lines.

In other ages, superstition associated disease with magic, witchcraft, the enchanter's wand, the evil eye. At the present day, the romantic conceptions of early days have taken a new departure. In the place of the all devouring, fabulous, mythological griffin, we have an almost infinitesimal particle or organism, varying from the 20,000th to the 40,000th part of an inch, playing the same part, continuing the work of destruction. On the slopes of Russian mountains destroying horses, oxen, sheep, men; on the fertile plains of France invading oxen, sheep, the silk worm; in the pastures of England and Ireland killing animals and men. The age of romance is not yet over. The knight of old has disappeared—sword and spear are thrown away; in their place we find the test tube and the microscope, modern weapons against disease producers and man destroyers. The fierce light of science bears rudely down upon old superstitions and old beliefs as regards the finite, proving to us that underneath the phenomena of disease, we have agencies at work operating in accordance with natural laws, linking as it were the past with the present. The myth of the earliest ages finds a certain degree of verification in the facts of the nineteenth century. Modern researches on micro-organisms read to me like a romance. Our savants, in studying these minute organisms were assisting not only in revealing the wonders of animated nature, but were benefiting at the same time the art of medicine. About thirty-five years ago a number of rod-like bodies were discovered in the blood, which were at first thought to be crystals of organic compounds, but it was found that these bodies grew, reproduced, and died; in other words that they manifested all the signs of vitality. Competent modern observers regard them as photo-phytic *fungi*, and had classified the *bacterium* as an organism capable of living on organic and inorganic matter, possessed of motion, and belonging to the vegetable kingdom. After describing the various species of germs and their classification, the lecturer said the researches of Drs. Dallinger and John Drysdale read like a story out of "Alice in Wonderland." They treated of an organism the minute character of which might be imagined when he told them that 30,000 could be placed in a pinhole. These men, who had followed the *bacterium* through all its phases from life to death, had now discovered the small granular white bodies or eggs from which the *bacteria* developed. Speaking of the heat-resisting capacity of the germs, he said they bore a temperature of 250 degrees; a little below that point they developed and went through all their stages as if they had never been heated. Just the same order and regularity were observable in the evolutions of the monad as in those of the highest forms of life. The *bacterium*, however, was a comparatively harmless agent; it fed on putrid matter, and thus served a purpose in the economy of nature.

(a) Abstract of a Lecture delivered at Halifax Literary and Philosophical Society, Nov. 22nd, 1881.

The *bacillus* was, on the contrary, a disease producer, a dangerous organism—a potent destroyer of life. This form was the cause of wool-sorter's disease. These *bacilli* consisted of cells and rods. The latter were of considerable length, and broke up into segments and separate cells. Passing on to the consideration of the germ theory, he referred to the works of Professors Tyndall and Grove, the latter of whom was, he said, the first in modern times to advocate the hypothesis, that living germs were the exciting agents of epidemic and infectious diseases. The lecturer stated that he had communicated Grove's name to Professor Tyndall, with some remarks as to his being the originator of this hypothesis, and observed that nothing could be clearer than Grove's exposition of the germ theory. He had a claim to be considered its modern originator. Grove was an Englishman, and we should feel a certain degree of national pride that this useful theory was formulated in England. Grove wrote to the lecturer as follows:—"The only merit I can claim from my work is, that I endeavoured to lay a foundation for more definite ideas as to the nature of the morbid poisons, both as regards their influence on the vegetable, as well as on the animal kingdom. And again, in pointing out the necessarily practical results that only by antidotes to these poisons, or prophylactic measures, could we ever hope for any great success in the avoidance of communicable diseases. I made sulphur an antidote for cholera, acetic acid for typhoid. . . . Dr. B. W. Richardson, though he differs from me in his views, has in *Nature* given me the credit for being the first in modern times to draw serious attention to a germ doctrine of diseases." The lecturer next touched upon Pasteur's researches on the silk-worm, which had been carried out to find a counter-agent to *pebrine* or silk-worm disease; he, by discovering a remedy, had saved millions to his country, and had restored to France her ancient industry. This was an argument, the lecturer urged, why all countries desiring to be great should encourage scientific studies, and aid in the establishment of free libraries and technical schools. Listerism or anti-septic surgery had sprung from Pasteur's researches. The eminent professor of surgery at King's College, London, had applied the germ theory to the dressing of wounds with most beneficial results. Commerce, surgery, and medicine had all gained by the researches of micro-organisms. The lecturer next described the researches of Branell, Pollender, Greenfield, and Koch on splenic fever—a disease due to the *bacillus anthracis*—and traced the connection of this germ and wool-sorter's disease. Of the latter disease, he said its pathology had only lately been cleared up. The links in the chain of causation in disease were made up of scattered facts. Primary causes operating in Russia, produced secondary effects in English manufacturing towns. Coming to the more recent researches of Pasteur on the causes of fowl cholera and splenic fever, he said it was another phase of the germ theory. By inoculating the tamed virus of fowl cholera and splenic fever, Pasteur has been able to mitigate those diseases, on the same *rationalis* as vaccination. If the premises of Pasteur were true, then the power of man over disease would be vastly increased. Pasteur was now experimenting with the virus of scarlatina and another formidable disease, puerperal fever. They had every reason to believe that scarlatina was caused by a self-multiplying germ from the outside world. Pasteur would cultivate scarlatina virus in his laboratory just as the gardener cultivated a rose or an apple tree. He would see what agreed and what disagreed with its life, and next he would experiment with it on some living animal. This brought the lecturer to the question of vivisection, and he continued:—"So much for the labours of Pasteur, and the latest development of his industry, of his genius, and, I may say, of his inspiration. Consider, for one moment, what may be the possible results of his discoveries. Should it prove true of all septic and contagious diseases, as of splenic fever and fowl cholera, that in the laboratory a vaccine to protect from each can be prepared, we are on the threshold of a discovery, which will so vastly increase the sway of man over those diseases before which we are now comparatively powerless, that we may, in time, eliminate them. What a priceless boon this will be to humanity. The illustrious Jenner, by the introduction of vaccination, conferred a boon on his race, on humanity, on the world, though, perhaps, the process of vaccination has not been altogether without its alloy. Proceeding on similar lines, Pasteur is continuing the work initiated by Jenner. The whole subject is, as yet, in its infancy, but results prove

that we have foundation for the hope for more brilliant, and even more practical achievements, as there are so many conscientious workers in the field. The ultimate benefits to humanity cannot be over-estimated. In the art of medicine we have it in its higher elements, in regions quite out of the ordinary practitioner's path. Medicine, to most minds, is associated with drugs, with the taking and giving of medicine, this is medicine in its lowest form. In its highest form it is seen in its connection with Biology, that science, which, as Huxley says, "makes one chain of causation connecting the nebulous original of suns and planetary systems, with the protoplasmic foundations of life and organisation." It is in this higher field we find the workers, who search for the explanation of diseased states in modified cell life, who search with the microscope for the organisms we have been considering, and who do so with the hope of establishing preventive medicine on a scientific basis, thus saving life and misery. It is in this field we find the experimental physiologists who are revealing to us the power of drugs over diseased states, who supply the scientific physician with the means of affecting in any desired sense the functions of any physiological element in the body, so that, as Huxley tells us, "It will, in short, become possible to introduce into the economy a molecular mechanism, which, like a very cunningly-contrived torpedo, shall find its way to some particular group of living elements, and cause an explosion there, leaving the rest untouched." You will, I trust, in conclusion, pardon me if I say a few words to you about animal experimentation, mis-called, as I have said, vivisection. I should like to take this opportunity of disabusing your minds about the practice and to ask you to consider this question rationally, I shall not say a word to hurt the most ardent anti-vivisectionist. (1st) Cruelty to animals is abhorred by medical men; I need not tell you I allude to unnecessary cruelty. (2nd) Experiments on animals are only made by scientific skilled physiologists; nearly all animals experimented on are rendered insensible by curare. (3rd) All we ask for is that our tried and trusted physiologists and surgeons should be allowed, under a certificate to conduct those experiments which they may deem necessary, without the harassing and annoying conditions which are almost prohibitory, and which are fatal to the advance of physiology. I know we have English talent in the physiological department of medicine, equal to any foreign talent, undeveloped, however, owing to the discouragement it receives. I would ask you to consider the present condition of the profession in England, and if you desire the advance of English medicine, to strengthen the hands of those who are advancing it, by your moral support.

To torture a living animal, under the pretence of research, deserves condemnation; no language is too strong to use against such iniquity. Let the act stand in force against such dabbles in science; with a ten-fold greater severity even than at present, let its punishment be increased, but let us discriminate. Pasteur, with all his honours thick upon him, loved, revered, with family ties, and everything that can bind him to life goes calmly down to the foulsome Lazzaretto, to try and find out the cause of yellow fever, to stamp it out as he stamped out silk worm disease. He goes with his life in his hand to slay disease. Colville and Payne (Englishmen) went to Astrakan to study the plague; they went forth nobly, as medical men should go, to confront the plague in its home. They exposed their lives, and I am convinced that the humblest member in my profession, is so imbued with its traditions, so educated, that, whether it be cholera, the plague, or typhus he has to encounter when called in, he will be at his post, faithful unto death. It is for those unselfish men, for Brunton, Frazer, Lister, Sanderson, Greenfield, Ewart, I ask your sympathy and support; for the leaders in medicine, who are striving in this prosaic weary work-a-day world, like the knights of old, to overcome the powers that surround us, the hidden, unseen, impalpable agents of disease and death, to bring them into subjection to laws of health, to benefit you and posterity.

THE statement published by several journals that cholera has made its appearance in Egypt is totally unfounded. On the contrary, the sanitary condition of the country is excellent, and not a single case of cholera has taken place.

Clinical Records.

EAST LONDON HOSPITAL FOR CHILDREN.

Two Cases of Calculus Vesicae in Girls, Removed by Rapid Dilatation of Urethra.

Under the care of MR. PARKER.

Communicated by MR. SIDNEY DAVIES, B.A.,
Clinical Assistant.

(With remarks by MR. PARKER.)

CASE I.—Emily M., *æt.* 5. was admitted into the Hospital on February 19th, 1881.

Previous Diseases.—Patient had had measles, scarlet fever, and whooping cough.

Family History.—The mother has had seven children, all living. No miscarriages. The father was a French poliaber, temperate and healthy. The mother is healthy.

Present Illness.—Two years ago the child complained of pain in passing water. This symptom improved for a time, and then got worse again. She had had nocturnal incontinence for several months. She used to "save it because it did not hurt to pass water at night." She now passes water very frequently and in very small quantities, and lately has got up several times in the night. The operation for removal of the stone was performed the day after admission by Mr. Parker. Chloroform having been administered, the child was examined bimanually per rectum and per hypogastrium. The stone was felt, and gave the impression of being small. The urethra having been dilated by a Weiss's three pronged dilator, a small pair of forceps was introduced and the stone seized. Several ineffectual attempts were made before the stone was extracted; at last it came out in small pieces. The calculus consisted of a uric acid nucleus and a coating of phosphate, the whole being surrounded by a thick layer of mucous, entangling calcareous material.

February 21st.—The temperature rose after the operation to 102°, and there were some rigors.

24th.—The child is comfortable. There has been no rigor since the 22nd, and the temperature has fallen to 99°. The urine dribbles away still. The urethra has returned almost to its natural size. The patient is taking bicarbonate of potash and hyosciamus.

25th.—The child is said to be able to retain her urine during the day. Passes two ounces at a time.

27th.—She does not wet the bed by day, calling when she wants to micturate, but still wets the bed at night.

March 2nd.—Patient still wets the bed at night. She can only retain her water a few minutes after the desire to micturate comes on.

9th.—Nocturnal incontinence continues.

The patient was discharged on the 14th. She came to be seen as out-patient on the 16th, when it was reported that she had only wetted the bed once since leaving the Hospital.

CASE II.—Ellen T., *æt.* 8, was admitted into the hospital on September 6th, of the present year. The patient had resided all her life in Limeshouse. There was no history of gravel in the family.

Previous History.—She had had symptoms of vesical calculus for nine months past. The first thing noticed was tenesmus of the lower bowel; this was followed by an almost constant dribbling of the urine and increased frequency of micturition. She also had suffered from an eczematous eruption about the vulva.

On admission, the patient had an ammoniacal urinous smell, and was obliged to pass her water every five or ten minutes. The urine was alkaline. There were enlarged inguinal glands in both groins, secondary to the eczematous condition of the thighs and vulva. On the day of admission the child was put under chloroform, and Mr. Parker examined the bladder with a sound. The stone was found to be a large one, and ensacculated in the anterior wall of the bladder near the fundus. The urethra was easily dilated so that the index finger could be introduced. The stone could be felt between the finger in the bladder and the other hand laid on the abdomen, the posterior part of the bladder being free and empty. Forceps were then introduced, and after two or three attempts, in which the external soft layer of phosphate was partially detached, the stone was successfully removed.

It weighed three drachms without the *débris* and measured about $1\frac{1}{2}$ by $\frac{1}{2}$ inch. The bladder was then thoroughly washed out with warm water. Considerable pieces of vesical mucous membrane entangling calcareous deposit were removed by this washing out.

The evening of the operation the patient's temperature fell to 96° and she vomited up everything given to her, notwithstanding the administration of ice and lime water. She complained of no pain. There was a good deal of sanguineous discharge, about 16 oz. Ordered chloral hydrate, gr. v., statim.

September 7th.—Temp. normal. Patient has had three hours good sleep after the chloral, and has been dozing this morning. Complains of no pain and looks very comfortable. Her urine dribbled away without causing any discomfort.

8th.—Temp. normal. The child is looking very well. The urine is a deep scarlet colour, strong ammoniacal odour, and deposits a sediment of ropy mucus, pus and broken down blood corpuscles; it is strongly alkaline.

Ordered Acid. nit. dil. $\mathfrak{r}x$;
Ext. belladon., gr. $\frac{1}{2}$;
Ext. hyoscyam., gr. v.;
Inf. buchu., $\mathfrak{z}ss$. t. d. s.

and to have fancy diet, with beef tea.

13th.—The child complained of pain yesterday for the first time. The urine passed during the night and early part of the day, is coffee coloured, ropy, strongly alkaline, the ammonia given off being sufficient to turn red litmus blue when held over the glass. Patient sleeps well and has a good appetite. The vulva to be smeared with vaseline.

20th.—Much improved. There is still an eczematous eruption on the vulvæ which are coated with a white incrustation. Ung. zinci. et vasel. is applied as before. The urine which has passed since 10 o'clock this morning is still ammoniacal and turns litmus paper blue, and it contains ropy shreds of blood stained mucus, but much less in quantity than a week ago. Temp. normal. General condition satisfactory. No control over the urine.

23rd.—Urine still alkaline, but very slightly. Patient has to-day for the first time called for the bed-pan for micturition.

29th.—Urine nearly clear and acid. Patient now has full control over her bladder, for a limited time, always calling for the bed-pan for micturition.

October 4th.—Urine has been once or twice alkaline since last note. To-day it is acid, but very cloudy, with urates, mucus, and pus. Less discharge from the labia. Her general condition improves daily.

6th.—Got up to-day.

11th.—Patient gets up daily. She retains her water during the night, but not always at night. Urine acid, but still cloudy.

21st.—For the last two nights patient has not wetted the bed. The urine is clear and acid, and the eruption about the labia is nearly healed.

23rd.—The patient was discharged to-day.

This girl was seen in the out-patient department a fortnight after her discharge. She had then full control over her bladder both night and day.

Remarks (by Mr. Parker).—All authors agree as to the comparative rarity of stone in the female bladder; but they disagree as to the actual percentage of the cases. The Norwich statistics show the proportion to be 1 to 19. It so happens that of my own cases I have had two females and three males during the same period. As regards symptoms, in both my cases they pointed to the rectum rather than to the bladder. Case II. had been under treatment at one of the large hospitals for some bowel trouble, the actual condition of things not having been recognised, although there was a strong urinous odour, together with an eczematous excoriation of the vulvæ. I have seen this condition before, and regard it in children as a most valuable sign in the diagnosis of calculus vesicæ. For some time before admission Case I. had been in the habit of holding her water during the day, because she could pass it during the night (unconsciously), without any pain. It is probable that, during the recumbent position, the stone fell away from the neck of the bladder, and so caused less irritation. In Case II. the stone was encapsulated in the anterior wall of the bladder. Thus while the child was on the operating table, after dilating the urethra, the stone could be felt by the finger in the bladder, and some difficulty was experienced in dislodging it, although it could be distinctly grasped through the abdominal wall.

Rapid dilatation has proved quite free from danger, and it offers a simple and ready means of access to or from the bladder. I doubt whether crushing, after Bigelow's method, would have proved more successful.

Special.

MEDICINE IN CHINA.—III.

16. *Plague*.—In the report on Amoy for the half-year ending 31st March, 1878, there is an article on the plague in China, prepared chiefly from notes by Mr. Rosher, of the Chinese Customs Service. These notes are believed to prove the existence of bubonic plague in China; that of late years the disease spread over a large area of the empire, and that it did not in reality disappear as believed by some writers.

In Yunnan, the sickness known as yang-tzu, otherwise plague, carries off yearly many victims in that province. It appears to have been imported from Burmah; its early history is imperfectly traced, but since the outbreak of the rebellion in that province it has spread among the population of it. A belief was expressed that its cause existed in exhalations from the ground, because animals that live in, or much upon it, suffered in an especial manner. After animals had suffered, the disease spread to man. Then the people employ such "sanitary" measures, as purifying their houses, lighting fires in every room, and abstaining from pork. The reporter states that in Yunnan he has seen many persons attacked by the disease, but few recovered. In places where the plague passes but lightly through, the mortality may be estimated at 4 per cent.; in places where it stops whole families disappear one after another, and the general population is decimated. In some districts the inhabitants, to avoid the pestilence, abandon their homes and harvests and camp out on the heights. Since, however, in some instances, the epidemic follows them, the dead are usually left exposed unburied; thus, the *Fung-shui* is not desecrated by their interment. But the odours from decomposing bodies is intense.

In 1871, 1872, and 1873, the epidemic began about the period of rice-planting, that is, in May or June, inward, during summer, which, in Yunnan, is also the rainy season, the disease continues, but in a mild form; after the rains have ceased, however, the disease becomes most active and deadly. Instead of visiting every village in its direct progress, it would pass some completely by, visiting places near to, and on, either side of them, to return several months afterwards to those forgotten spots, when elsewhere it would appear to have died away. After having devastated villages in the plains, it often ascended mountains and there affects severely the aborigines. It was constant among the Imperial troops, during the years named, while they were operating against the Mahomedan rebels.

17. *Filaria Disease—Chyloderma*.—With regard to the occurrence of filaria disease at Amoy, 1879, the reporter quotes various opinions in favour of, and adverse to, the theory of the relation of filaria to lymph scrotum and elephantiasis. He then enters into details with a view to support his belief that the parasite and disease are related in the manner of cause and effect. He observed six cases of this affection, all of which had this feature in common that in them there was enlargement of the inguinal glands. In the clear lymph obtained from them there were abundance of filariæ, although none in blood obtained from the finger.

In some instances lymph scrotum was associated with elephantiasis; in others not so. In those of elephantiasis, attended by inflammation of the leg, the attendant pyrexia was designated *elephantoid fever*, also *transient fever*. Then follow remarks as to whether filariae are oviparous or viviparous; as to the specific alliance between those entozoa and those found in the *Corvus torquatus*, the *Goura coronata*, and the dog. The reporter had examined a number of patients "with the result of finding that, unless there is some disturbance as fever, interfering with the regular physiological rhythm of the body, filariae embryos invariably begin to appear in the circulation at sunset, their numbers gradually increase till about midnight, during early morning they become fewer by degrees, and by 9 or 10 o'clock in the forenoon it is a very rare thing to find one in the blood." This diurnal periodicity is accounted for after this manner: "The nocturnal habits of *filaria sanguinis hominis* are adapted to the nocturnal habits of the mosquito, its intermediary host," and then a dissertation more or less conjectural upon the stages through which this filaria embryo is stated to pass. The present object is sufficiently obtained by simply transcribing these particulars, adduced, as they are, with the evident desire to support a theory.

18. *Cholera*.—The reports before us contain valuable reference to the history of cholera in China, as given by native authors. As in India, so in China that scourge has been recognised as existing from time immemorial. At a period 2,500 years before our era it was described by the very name it now bears—"huo-luan"—an expression meaning something huddled up in a confused manner inside the body, and which is evidenced by vomiting and purging. As to the early theories of its etiology, an author, during the Tang dynasty, A.D. 620—697, attributed it to food and not to demons; a second, of the Yuen dynasty, A.D. 1280—1368, ascribed it to retained ingesta aided by external influences, such as cold, by which the male principle or *Yang* ceases to ascend, the female, or *Yin*, to descend; thus the diaphragm is drawn down. An author of the Ming dynasty, A.D. 1368—1644, ascribes the disease principally to heat, for the reason that it prevails most in summer and autumn, and very rarely at other times. Accepting the views thus expressed by competent inquirers that cholera is one of the oldest diseases of which a distinct description exists, writers are struck with the small number of widespread epidemics which, from early times, have travelled eastward from India to China, compared with those which have extended westward, not only to the very furthest limits of Europe, but far beyond. The natural barriers eastwards are not more formidable than in the west; the habits of the Chinese, the conditions under which, densely crowded, they live in walled cities, the extreme filth which everywhere abounds at the doors and around their dwellings would seem eminently adapted to foster and propagate the malady, and yet on former occasions, as so recently as 1877, while Japan has been severely devastated by epidemic cholera, China, still nearer the cradle of the disease, has comparatively, if not altogether and absolutely escaped. The flood of travel westward alike by land and sea, has for generations far exceeded the currents eastward. But the reporters in China accept the explanation thus indicated as only in part sufficient. The occurrence of epidemic cholera in China is first stated to have taken place in 1669, on which occasion it was believed to have been brought from Malacca. In 1761 and 1769 it prevailed in the Coromandel, and shortly after the latter date was conveyed to China. The epidemic of 1817 extended from Bengal to Dacca, thence north eastward along the

Bramapootra to Rungpore, and onwards to the borders of Thibet and south-western China. In 1820 it made its first appearance in Canton, whence, as from a focus, it penetrated into the interior of the Empire by direct route; it radiated to Ningpo, and thence upwards along the Yangtze Kiang. In 1821 it reached Peking, where, in 1822, and again in 1823, it prevailed, forming the centre of infection in Northern Asia. In 1826 it was again borne from India to China; it reached Peking, whence, advancing, it crossed the Chinese wall, swept through Mongolia, and onwards to Moscow. In 1840, by means of the expedition from India, the disease once again reached China. It travelled to Peking, thence by caravan route westward to Russia. It 1841 it prevailed in malignant form at Ningpo; in 1842-3 it affected the men of the British East India Squadron. From that date a lull in its record appears, lasting fifteen years. In 1858 it reappeared, and year after year continued to do so till 1867. Then another lull till 1877.

19. *Conclusion*.—And so could we continue our analysis of the reports by medical officers at the several Treaty ports in China; while also it were practicable, if expedient, to add remarks obtained from similar reports regarding consulates in Japan. But the present object will be attained if, by the remarks now made, the attention of the profession generally be directed to the valuable store of information in progress of being accumulated, and twice in each year made available for general use through the forethought and energy of the Custom's officials and medical officers scattered throughout the chief maritime and river ports of China.

CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 25TH.

The President, JOSEPH LISTER, F.R.S., in the Chair.

Dr. F. A. MAHOMED ON

TWO CASES OF DIRECT TRANSFUSION OF BLOOD FOR HÆMORRHAGE IN TYPHOID FEVER.

The first case was that of an unmarried man, 26 years of age, who was stout, rather bloated looking, and thoroughly out of condition; he passed through an anxious attack of enteric fever, complicated during the latter part of it by wakeful, excited delirium, resembling that of "delirium tremens," a complication not unfrequent during the defervescence of the specific fevers, and, perhaps more especially liable to occur in persons addicted to the excessive use of alcohol. He relapsed on the 25th day of his illness; on the 10th day of his relapse, and the 35th of his fever, he had a severe hæmorrhage, which recurred twice on the following day. Exhausted, anæmic, restless, with cold extremities and a very small, thready and often irregular pulse, about 160 per minute, he was evidently fast sinking, when transfusion was performed, with the immediate result of bringing down his pulse rate from 160 to 144. After this he rallied for a few days, and even gained ground so much as to give great hopes of his ultimate recovery. Six days after the operation hæmorrhage recurred to a small amount which caused a sudden change for the worse, one or two more slight discharges of blood soon reduced him to a state of exhaustion, from which he could not recover. He died nine days after the operation, on the 19th day of his relapse and the 44th of his fever. The second case was that of a married man, who had a young family dependent upon him. He was 25 years of age. A powerful, well made man, who during his attack of fever suffered a probably irrecoverable injury by collapse of a large part of his right lung, while in addition to this he had severe general bronchitis. On the 26th day of his illness he too had a relapse. On the 5th day of his relapse and the 31st of his illness, he

also had a severe hæmorrhage; four days later he had three more severe hæmorrhages, and relapsed into a state of complete exhaustion and impending dissolution. On the following day when he appeared to be "in extremis," transfusion was performed with the best possible effects; for two days he rallied greatly, when during the exceptionally cold weather, his bronchitis increased, and he died from the lung complication on the 5th day after the operation, on the 15th of the relapse and the 40th of his fever. Dr. Mahomed gave some statistics showing that the average frequency of hæmorrhage in enteric fever was about 7 per cent. of all cases, and that about 50 per cent. of these were fatal, more than half of the fatal cases of hæmorrhage lost their lives as a direct result of the bleeding, and that it was in these cases more especially that the operation might be called for. He estimated that it might prove of service in about 20 cases out of 1,400 cases of enteric fever. Each case must be judged on its own merits, and he would advise its performance whenever the patient was sinking into a dangerous condition, as a direct result of the loss of blood. He claimed that by means of it fatal exhaustion and syncope might be warded off, and time given for the action of remedies, a ready stimulant and food supplied to the heart and tissues; and the danger of destructive ulceration of the intestines during exhaustion and anæmia be diminished. He advocated only direct transfusion of human blood by means of Aveling's transfuser, with a small expansion and no valves. He referred to Professor Schäfer's report to the Obstetrical Society in 1879, as proving the uselessness of the blood of the lower animals or saline solutions for this purpose.

Mr. BARKER said it would be interesting to have the experience of those who had employed Roussell's apparatus. He had used it during the past summer on a patient of Dr. Barlow's, the subject of pernicious anæmia. Blood in plenty was yielded by the brother of the patient, and in both donor and recipient the vein was exposed without difficulty. From this stage of the operation, however, troubles arose. In the first place the forcible pressure exerted by the instrument created embarrassment, followed by trifling leakage and subsequent coagulation of the blood within the tubes, after which no good could be effected with the apparatus. Direct injection of defibrinated blood was then resorted to; but little benefit resulted, the patient dying shortly after. His own experience, therefore, was fatal to the use of the instrument.

Dr. COUPLAND inquired if Prof. Schäfer's suggestion to remove blood from an artery of the donor had been considered by the authors of the paper, the reasons urged for the preference being the greater pressure under which the fluid was thus obtained, and its higher stimulating power. Dr. Coupland considered arteries more favourable as a source of supply on several grounds, and while admitting as an objection the difficulty of estimating the quantity drawn off, he thought this would not be insuperable.

Mr. R. W. PARKER related the circumstances under which he had seen Roussell himself use his own apparatus to transfuse blood into a patient in the London Hospital, on whom Mr. James Adams had performed amputation at the thigh. The operation failed through a mere accident caused by a dresser overturning the instrument. Mr. Adams yielded the blood employed, and but for the mishap all might have gone well.

Mr. HAWARD said it was desirable to ascertain the best mode of performing so important an operation as transfusion, and all instruments should be of the simplest description possible. He had seen Roussell's apparatus in use. The chief advantage claimed for it was that blood coagulated less rapidly in it, but this could not be observed, because of the number of valves and complications. In a case of pernicious anæmia under the care of Dr. Cavafy, he had employed this instrument, and found no difficulty in getting it into action, but when about four ounces of blood had passed from arm to arm further action was arrested, and on examination it was found that a coagulum had formed on the interior of the syringe, which was roughened. The patient in this instance showed some improvement, but he had not been encouraged to resort to the use of this particular apparatus often. Dr. Aveling's improvement in the construction of transfusion apparatus marked a considerable advance, but in a perfect instrument there ought to be no valves whatever. Introduction of the canula would be assisted by pinching up the vein, and holding it so. Mr. Haward added that he had assisted Mr. Smith in injecting defibrinated blood into a patient with temporary benefit; and in reply to a question from Mr.

Parker, explained that the instrument he condemned was one of Roussell's own make.

The PRESIDENT, agreeing that simplicity should be a first desideratum in transfusion instruments, advocated the use of ordinary glass syringes and defibrinated blood as preferable to any other means for the purpose. The operation should be carefully performed; the vein of the recipient first being exposed, blood from the donor should be received into a vessel, defibrinated and injected with the syringe; the basin should be scrupulously cleaned before being again used to hold the second supply of blood, and the same measures repeated as required. Thus all complications and risks might be avoided; the apparatus was always ready, and procurable at short notice. The danger to the donor in these cases he thought to be much exaggerated. There could be none, provided the skin and instruments were properly purified, and the incision protected by a purified pad. He explained that some years ago he had shown coagulation to be due to contact of the blood with solid matter of some kind, such contact even for a short time sufficing to bring about the change. During transfusion this tendency was favoured very much, and yet blood so transfused did not coagulate, it thereby being proved that the animal economy by some means overcame the tendency once set up.

Dr. MAHOMED said much less than ten ounces of blood were needed to produce favourable results. In his last case four ounces only were used, the effect being markedly good. He thought the question as to source of the blood not sufficiently discussed. It was manifestly unfair to submit hospital attendants to the risk incurred by donors, and he could not but consider that insertion of a canula was a more dangerous operation than that of ordinary phlebotomy. He had in one case adopted antiseptic precautions, but could not carry them out in detail, the conditions of emergency being so against it. The incision made into the vein should not be longitudinal, but transverse and valve-like. The question of artery v. vein was really unimportant, since the newly-received blood underwent arterialisatio*n* speedily after entering the body, and before its actual reviving influence was experienced to any great degree.

Mr. CRIPPS explained that he had perfected Dr. Aveling's apparatus by the omission of all valves and stop-cocks, thus simplifying it to the greatest possible extent.

The PRESIDENT announced that a patient was on view in the waiting room, the subject of typical chromidrosis, and suggested the appointment of a committee consisting of Drs. Cavafy, Radcliffe Crocker, Stephen Mackenzie, Hewett, and Fox, to report on it, and the similar cases described previously by Dr. Crocker.

This was agreed to

Dr. T. WHIPHAM ON

THREE CASES OF CONTINUED FEVER WITH AFFECTION OF THE SPLEEN, IN TWO OF WHICH AN EXTREMELY HIGH TEMPERATURE OCCURRED BEFORE DEATH, AND ONE OF WHICH CLINICALLY RESEMBLED ENTERIC FEVER.

The cases had come under Dr. Whipham's observation during the past three years. *Case I.* was a domestic servant, æt. 20; had enjoyed excellent health, and save that she was an inordinate meat eater, was guilty of no excesses. Five weeks before admission into hospital, she was attacked by headache; vomiting, and profuse sweats set in about nine days before she came under observation; at this time she complained of abdominal tenderness. While under treatment the symptoms were but little altered, and on the 38th day she was suddenly attacked with severe pain in the left iliac region; so severe was this pain, that she never ceased screaming until her death in the evening. At the autopsy a few yellowish white masses of irregular shape were found in the spleen, giving the general impression of infarcts; no other organ showed any appreciable change from the normal condition. *Case II.*—A domestic servant, æt. 21, had been remarkably free from illness, and had never been seriously ill save when she had chicken-pox as a child. She was in perfect health four days before admission, when she took a warm bath, after which the catamenia appeared, but ceased in about three hours, and she was then attacked by abdominal pain, chiefly in the hypogastrium, and also in the legs and back. She had lost two brothers and a sister from phthisis. After four days rest in hospital she was so much better, that she was allowed to get up, but eleven days later she was unable to stand, and had fits of alternate laughing and crying; was constipated and complained of pains on the top of her head. On July 1st,

1878 (eighteen days after admission), her pulse was 104, and the temperature still normal, but she was delirious and so noisy, that she was removed to the separation ward. She became gradually worse, and died on July 11. The temperature having risen to 109 deg. F. shortly before her death. At the autopsy a few circumscribed dark red patches were found in the spleen, which contrasted strongly with the general brick red colour of the organ. Beyond some congestion of the lungs, no other morbid change was found. *Case III.*—A domestic servant, *æt.* 26, was attacked about November 10th, 1880, with many of the symptoms of enteric fever, and was admitted on November 24th. Next day several rose-coloured spots were found on the abdomen indistinguishable from typhoid spots. Diarrhoea persisted, the patient became very weak and then delirious; the abdomen tympanitic, on December 1st the diarrhoea was profuse; pulse 168, and she died in the afternoon. About ten minutes before death her temperature rose to 108.6 deg. F. At the autopsy the spleen weighed 16 ounces, in its substance was a large infarct partially broken down; the tissue of the organ was diffident. The solitary glands of the intestines were unusually conspicuous, but no other abnormality was found. The cause of the disease was in each case obscure. Two explanations suggested themselves, viz., blood poisoning or local inflammation of, or in the neighbourhood of, the spleen. The weight of evidence pointing rather to the latter. The absence of any history pointing to splenic affection is remarkable, as also is the fact that, these three patients were all female domestic servants, and of about the same age. The high temperature which was observed in Cases II and III is noteworthy.

Dr. THEODORE WILLIAMS asked if the brain and spinal cord had been examined, with a view to throwing light on the cases.

The PRESIDENT said that recent investigations on lower animals had shown numerous blood diseases to be dependent on the presence of different minute organisms, and that consequently it was usual to examine the blood in all obscure diseases before death with a view to determine the presence or absence of bacteria.

Dr. WHIPHAM replied that the brain had been examined in three cases, and the cord in one, but that the blood was not examined. The condition of the spleen, however, might be taken to negative the theory of blood poisoning.

OBSTETRICAL SOCIETY OF IRELAND.

FIRST MEETING OF THE SESSION, SATURDAY, NOV. 26TH.

ABSTRACT OF THE INAUGURAL ADDRESS BY THE PRESIDENT, J. AUGUSTUS BYRNE, M.B. Dub., L.K.Q.C.P., M.R.I.A., Professor of Midwifery and Diseases of Women and Children in the Catholic University.

AFTER thanking the Fellows for the distinguished honour conferred on him in his election as President of so ancient a Society, he spoke of the many deaths which had occurred in their midst since the last session was opened. Among these were Dr. Halton, of Kells, Dr. Rainsford, Dr. Cryan, and Dr. Alfred McClintonck, of Dublin. To the memory of the latter he paid a well-merited tribute. He said: This is not the place, nor is this the opportunity, to write a memoir of our lately departed President and friend. It would, however, be scarcely compatible with the respect which we all entertained for him and with our admiration for his abilities if I in this address, the first which has been given in this hall since his decease, did not say a few words of his early history. Dr. McClintonck was born in Dundalk, and at a very early age became a pupil of Dr. Brunker; thence he went to Paris, where it has been stated to me, that in that gayest of capitals he devoted himself so exclusively to study, that he never enjoyed the gaieties of it like other students. From Paris he went to Edinburgh and Glasgow, where he graduated in medicine in 1844. He became a Licentiate of the Dublin College of Surgeons in 1842, and subsequently a Fellow in 1844. In 1848 he, in conjunction with the late Dr. Hardy, published his work on "Midwifery," and this was followed in 1863 by his treatise on "Diseases of Women"—a book replete with useful information and learning—his first essay being a most useful and instructive addition to our knowledge of obstetrics, and worthy of that hospital which had afforded him, from its great numbers, &c., the means of enabling him to glean

statistics and facts of a highly interesting and important nature. His latest contribution to the store of obstetrical literature was his edition of Smellie's "Midwifery," published by the Sydenham Society. For Smellie he had always entertained a great admiration, and there is not much doubt that it was in some measure due to his familiarity with his works that he was indebted for that terseness of style and that vividness of language which distinguished him not only as a writer but as a speaker. From every quarter he was presented with honorary distinctions, and his name was enrolled on the list of most of the special gynecological societies in other countries, and since the year 1881 two of the highest professional honours were conferred upon him—viz., on the death of the late Dr. A. Hudson he was appointed by Her Gracious Majesty to the vacancy on the General Medical Council of the United Kingdom, and he was also selected to fill the Presidential chair in the Gynecological and Obstetrical Section of the great International Congress, 1881. What stronger proof can be assigned of the great estimation in which he was held by our distinguished *confreres* in London than their selection of him for this position, which could easily have been filled up by a selection amongst the eminent specialists of London? It may be regarded as a tribute of their admiration and gratitude for the many and constant efforts which he had used to improve our knowledge, and of the great personal esteem in which he was held by them. Of his conduct during that short term of office it were needless for me to speak. With all the multitudinous subjects brought before the Sixth Section he displayed an intimate acquaintance, with most of them practically, and with others theoretically; and the event proved that the council of management of this great medical gathering could not have selected one more highly gifted to fill the office. He was highly cultured, impressive, resolved in his manner, and was a model of courtesy.

Ah, how little did any of us then assembled on the day of his opening address in our section suspect that he, our President, would soon be gathered with the illustrious dead, whose history he had compiled and brought before the notice of the many distinguished men *frères* assembled in a most pleasing and instructive memoir. But let us hope that the influence of his name and his reputation will live long, and that his life-long labours in the branches of the profession, which he cultivated so well and so ardently, will be an example to others to imitate and follow, and, if possible, to excel.

Since the commencement of my Presidency an event of great importance has occurred, one which not only affects the interests of this Society, but also of medical education—I allude to the representation of obstetrical interests on the General Medical Council of Education and Registration of the United Kingdom. The Report has furnished to you the details of the action which your Council took upon the death of Dr. A. Hudson, in order to have a special representative appointed by Her Majesty in his place, and also has told of the success of the joint applications of this and the London Society that at least there should be one representative of it on the Council. Her Gracious Majesty, by the advice of the Lord President of the Council, Earl Spencer, hearkened to the prayer of our memorial, addressed and presented to His Excellency Earl Cowper, Lord Lieutenant of Ireland, and the result was that the late Dr. McClintonck was selected to fill the vacancy; and I think that I express the opinion not only of this Society, but also of the medical profession here and in England and Scotland, but this appointment was the means of giving great satisfaction, inasmuch as in the first place the condition of obstetrical and gynecological education required it; and, secondly, no better selection could have been made, for reasons into which I need not enter here, than that of Dr. McClintonck; and I trust that in the filling up of the hiatus caused by his greatly lamented death, the same cogent reason will have weight with the Lord President, Earl Spencer, and that he will continue the appointment in the same line as heretofore; for what do we find on analysing the list of the names of the Council? That out of the twenty-three names constituting the Council there is not a single one representing this great and important branch, nor ever has there been one, since the formation of that Council until the late Dr. McClintonck was appointed. Corporationism and collegism, medicine, surgery, pharmaceuticals, have all had representation, but this great section of medical science was passed over, and no one on that Council—I say it with much respect for the eminent gentlemen constituting it—could be supposed to be familiar with its needs and requirements, nor with the great advances which it has made of late years—an advance un-

equalled in any other department of medicine and surgery. I trust, therefore, that the attempts now being made by the advocates of the plan to induce those in power to discontinue this special representation and to hand back this one seat upon the Council to other quarters may not be successful, and that the extract from *The Medical Press and Circular*, published in yesterday's papers, will have no weight or force in guiding the action of those who advise Her Gracious Majesty, who has always manifested much interest in everything that concerns the health and wellbeing of her own sex, of which she is so bright an ornament.

It would be scarcely compatible with the position which I occupy here this evening were I not to make some allusion to the great event which has occurred during the autumn of this year—the meeting of the great International Medical Congress in London. This, the seventh session of this great medical association, which comprised so many celebrated names, has just passed away, and must mark an era in medical science. I believe that it has been the largest gathering of medical men which has ever taken place, and when I say that 3,200 names were inscribed on the roll of names it will give some idea of the vast numbers of medical savants from every part of the world who came to London to instruct, to learn, and to add to the pile of knowledge which has been accumulating since the earliest birth of medicine.

This great medical army, marshalled by its different generals, during its brief but brilliant campaign, proceeded from victory to victory, overcame obstacle after obstacle, and achieved successes which could not have been achieved in any other way; for in the discussions which took place in the different sections truth could not fail to be elicited and error to be exposed. To our fellow-countryman, Dr. (now Sir) W. MacCormac, much, if not the greater part, of its success is to be attributed, for it was by his talents and skill and energy that this great undertaking was inaugurated, commenced, carried out, and brought to a glorious termination. He as honorary secretary, and with the aid of his eminent confrères in London, was mainly instrumental in organising this vast army, and gained his laurels by his great skill and talents, for he was honoured by Her Gracious Majesty at the termination of the proceedings by being offered the distinction which he can proudly wear—a distinction which met with the approval of the entire medical profession in foreign countries, in London, and here in Ireland.

Department of Lunacy.

LUNACY IN NEW ZEALAND.

It is a gratifying reflection to us that last year we stood, as we believe, alone amongst English medical journals in affording support and encouragement to the late Dr. Frederick Skae, Commissioner in Lunacy in New Zealand, in the laborious and disheartening work in which he was engaged in that colony. That work at length proved overwhelming, and Dr. Skae unhappily sank beneath it in June last in the thirty-ninth year of his age, but not without leaving behind him monuments of his zeal and patient persistence in a good cause. The state of the lunatic asylums in New Zealand is still, we fear, in many respects deplorably bad, but it is very different from what it would have been, but for Dr. Skae's unselfish toil, and very different from what it was when he entered on the duties of his office eight years ago. In spite of obstruction and misrepresentation Dr. Skae went on manfully making the best of the miserable machinery at his disposal, and if he failed in approaching his own ideal, or even in bringing the institutions under his supervision into a state of moderate efficiency, the fault was not his but that of the system in which he found himself involved. The lunatics of the colony have even now cause to feel grateful to his memory for the ameliorations of their lot which he introduced.

All the lunatics in New Zealand would not fill one of our large English asylums. They numbered only 1,125 on the first day of the present year, but they are distributed in seven asylums at wide distances apart, and some of them only to be reached by long sea voyages, so that the visitation of these institutions is an arduous undertaking. And if the visitation of the asylums is arduous, the adequate inspection of their inmates must be still more troublesome and laborious, seeing how they are huddled together. On the 1st of January last there were in all, in the seven New Zealand asylums, 232 patients in excess of their proper accommodation, an amount of overcrowding that ought to keep alive serious apprehensions of epidemic disease, and that must occasion incessant disorder and turmoil in the wards. Steps are being taken to relieve this overcrowding, new wings being now in course of erection at the Auckland and Christchurch asylums, and a temporary building having been raised at Sealiff to receive the overflow from the Dunedin asylum. If, however, overcrowding is to be permanently avoided still more extensive enlargements must be begun forthwith, as the lunatic population is increasing in New Zealand even more rapidly than in England. It has doubled itself in eight years and no abatement is apparent in the rate of increase. If the moral treatment of the insane is to be adequately carried on, not merely enlargements but new asylums will be required, provided with dining halls, chapels, bath-rooms, work shops, and suitable quarters for a staff of officers, and especially of medical officers upon whom the future success or failure of the New Zealand asylums must entirely depend. The present state of matters is not only discreditable to the colony but is cruel and extravagant, as may be gathered from the following statement by Dr. Skae, introduced into his report on the Dunedin Asylum.

"It is no exaggeration to say that many of the present patients have gradually lapsed into hopeless dementia, partly owing to the utterly unfavourable circumstances by which they have been surrounded in the old asylums, and that they would in all probability have recovered had they been treated in such a place as the new one will be."

Mechanical restraint is still too freely and indiscriminately resorted to in the New Zealand asylums, but it is, of course, impracticable to put stringent restrictions on its employment until suitable asylum buildings are secured, and much of the present pernicious system of management amended. Only two out of the seven asylums have resident medical superintendents, and these are miserably underpaid. At Auckland Dr. Young, whose services the Commissioner highly commends, receives a salary of £383, and at Christchurch Dr. Bacon appears to receive only £166. Men fit to hold such appointments and able judiciously to perform the varied and onerous duties connected with them ought to receive £600 or £700 a year, and Dr. Skae's successor ought to be offered £1,000 per annum. After the lamentable fate of Dr. Skae who received only £800 per annum, no one in this country really qualified to fill it would think of accepting it for less than the annual honorarium named.

The average cost per head per patient in the New Zealand

land asylums during 1880, less payments, was £36 15s. 1d., a sum which appears to us considerably too low considering the wages paid to nurses and attendants. The highest cost per head was at the Nelson Asylum and amounted to £34 16s.; the lowest was at Dunedin, and reached only £19 2s.

Notwithstanding the defects in the New Zealand asylums the death-rate in them for 1880, calculated on the average number resident, was only 6.89, and thus considerably lower than the average rate in county and borough asylums in England, which for 1879 was 10.59. Of the 64 deaths reported, 47 were due to diseases of the nervous system, 12 to diseases of the lungs, 3 to heart disease, 8 to abdominal disease, 1 to ruptured intestine, 1 to suffocation by a piece of meat getting into the wind-pipe, and the remainder to various other causes. General paralysis proved fatal in 13 cases, and epilepsy in 6.

THE CAUSES OF INSANITY.

UNTIL the medical superintendents of lunatic asylums can obtain some really useful information about the causation of the mental disease in the cases falling under their notice, we should recommend them to abstain from wasting the money of the ratepayers in printing in their annual reports, elaborate tables purporting to deal with this subject. In the report of the South Yorkshire Asylum which lies before us, we find a table giving the assigned causes of insanity, in the patients admitted during 1880 in which a cause is stated in just 135 out of 494 cases. In 359 cases the cause is said to have been unknown. The utility of such a table is obvious on the face of it. But the table contains worse errors than mere imperfections, betraying a kind of careless confusion that is inexcusable. Thus the same cause figures in it repeatedly under different names, as for instance "business affairs," which reappear as "losses in business," as "trouble" and as "worry and anxiety," or "change of life," which again presents itself as "suppression of periodic discharge," or "excessive study" which comes up a second time as "over work" or "poverty," which disguises itself lower down as "distressed circumstances." These forms of mental diseases are set down in this table as causes, as for example, "puerperal mania" and "low-spirited." Again, new and startling causes of insanity are invented in it, such as "false impressions" and "getting into debt," whilst in successive items it oscillates between hopeless vagueness and perplexing precision, as when it charges "imbecility" and "husband being in prison," "weakness" and "loss of a house" equally with the production of mental derangement. We are at a loss to imagine why this table should have been printed unless to throw discredit on those who compiled it, or to bring etiology into ridicule. A more reasonable table was quite within the range of possibilities. No one in the slightest degree acquainted with lunatic asylum practice can believe that it was impracticable to trace more than six out of 494 cases of insanity to intemperance, or more than one out of that number to senile changes. A very trifling exercise of consideration and research would have made the table if not instructive at least intelligible. Better no tables at all than such as this.

RESIGNATION OF DR. SHEPPARD, COLNEY HATCH ASYLUM.

DR. EDGAR SHEPPARD has resigned his medical superintendentship at Colney Hatch Asylum, after a term of office extending over twenty years. The Committee of Visitors have been unanimous in the expression of sincere regret at losing Dr. Sheppard's valuable services, and in conjunction with the staff generally and all the employes of the establishment, have determined to present Dr. Sheppard with a testimonial to indicate their relationship towards him and their sorrow at losing him. Dr. W. J. Seward, M.B. Lond., one of the assistant medical officers of the Asylum has been appointed to the vacant post.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Bro. Hauteville, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLIAMS and ROGERS; Philadelphia, by Dr. BRINTON, post free in advance, 5j dollars (£1 2s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order

ADVERTISEMENT SCALE.—Whole Page, 25 0s. 0d. Half Page £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth Page, 12s. 6d.

Small Announcements of Practices, Assistancies, Vacancies, Books, &c., of Seven lines or under, 4s. per insertion; 6d. per line beyond. Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 30, 1881.

MEDICAL REGISTRATION AND THE ERASURE OF NAMES.

THE system which has been hitherto adopted for purging the Medical Register of errors has been brought to something like a dead lock by a recent judgment of the Courts, in a prosecution instituted by the Medical Alliance Association. The defendant's name did not appear in the Register, and he was, in consequence, prosecuted for illicit practice; but it turned out that his

name had been once on the list, and had been erased because he did not reply to the inquiry letters addressed to him by the Registrar. The 14th Section of the Medical Act, under which this erasure is effected, is as follows:—

“To enable the respective Registrars duly to fulfil the duties imposed upon them it shall be lawful for the Registrar to write a letter to any registered person, addressed to him according to his address on the Register, to inquire whether he has ceased to practise, or has changed his residence, and if no answer shall be returned to such letter within a period of six months from the sending of the letter it shall be lawful to erase the name of such person from the Register, provided always, that the same may be restored by direction of the General Council should they think fit to make an order to that effect.”

Now, under this Section great activity has recently been displayed, and numbers of practitioners have been “disestablished” as practitioners. The Minutes of the Executive Committee of the General Medical Council just issued contain the names of sixty-eight medical men who paid the fine of 5s. to have their names reinstated; and these are only a small proportion of the whole who were struck out of the Register, although they are alive, and in practice.

Up to the delivery of the legal decision in the case to which we refer, it has been held to be the business of every practitioner to see that his name and address are correctly published in the Register, and he has been held liable to prosecution for illegal practice if he omitted to do so; but now it has been ruled that the duty of maintaining the accuracy of the list devolves upon the Medical Council, and that an erased registrée may go on in practice, and enjoy all the privileges of registration, even if he has long ceased to appear in the official list.

We assume that this judgment will—as it certainly ought—put a stop to the wholesale “scratchings” of medical men which have recently taken place. We can answer for the fact that the Irish Branch Council have struck off the roll many practitioners, some of whom are still extant, and in practice at their original address, and—we believe we may add—have deprived such persons of the registration, for which they originally paid £5, though they knew that such practitioners were neither dead nor gone away. Whether or not this has been done in order to force these persons to pay the fine of 5s. we are unable to say, but that it has been wilfully done we have unquestionable evidence.

The arrangements for correcting the Register are, indeed, most unsatisfactory, and great injustices are inflicted thereby. In the first place, most country practitioners are absolutely careless about answering circular notes; in fact, not more than one in three of them will take the trouble even to read such a missive. Are they to be punished for their unbusiness-like and negligent habits by deprivation of their professional privileges? We certainly think not. Then again, the Post Office Returned Letter Department is absolutely untrustworthy and miserably ineffective. It publishes regulations to the effect that all undelivered letters and circulars shall be returned to the sender; and, probably, the Medical Council officers are under the impression that their note

—not being returned to them—has reached the person to whom it was addressed. Such an idea, we can testify, is perfectly delusive, for not in one case out of twenty do the postal authorities comply with their own regulations. Thus a practitioner who has changed his address may expect to find his name erased from the Register, simply because the Post Office has not taken the trouble either to send the letter after him or to return it to the Medical Council.

We commend to the attention of the Registrars this matter, and we invite them to devise some method of keeping the Register free of error without depriving large numbers of medical men of their rights. Of course, any new method must be legalised in some future Act of Parliament before it can be put in operation; and, meanwhile, we hope that the Registrars will content themselves with removing the names of persons whom they know to be dead, and refrain from making use of the 14th Section, under which these difficulties have arisen. Should they continue these wholesale erasures, we shall have a new class of practitioners created, who are qualified and were once registered, but of whom the official list takes no cognisance, and endless confusion will arise therefrom.

THE ROYAL COMMISSION ON FEVER HOSPITALS.

It is, perhaps, a fortunate circumstance that nothing further is demanded of Royal Commissions than that they should consider evidence bearing on the existence of evils, and suggest measures of relief arising out of such consideration. Were it to be required also, that effect should, through the agency of the Commission, be given to the plan recommended by it, it is to be feared that opportunities for improvement would not often present themselves. Especially might this be so in the case of the Royal Commission last appointed, that, viz., on fever hospitals, and the members of which we were able to announce in our last issue. That something must ere long be accomplished to rescue the metropolis from the miserable confusion heaped up by the incompetent efforts of the Metropolitan Asylums and the Poor-law Government Boards, is abundantly clear. It is indeed only too evident that nothing further can be expected from the body which exercises official sway in this particular; and nothing, it must be added, could well be worse than the chaos in which matters now are in all connected with the management of small-pox and fever cases within the London area.

The work before the Royal Commission, indeed, is a labour of almost incalculable magnitude; ere it can succeed in performing its duty it will have to introduce order where worse than disorder is now reigning; or, at least, it must make such suggestions as shall, on being carried out, ensure a change in this respect. Not only will it be called upon to adjust conflicting claims of rival interests, but it must attempt the more difficult task of allotting the degree to which individual rights are to be respected in one of the most important relations of citizen to citizen and to the State that can be imagined to exist. In fact, whatever light it may be regarded in,

the work of the Commission is both delicate and arduous, and hence it is that a sensation of relief is experienced when the names of those entrusted with so grave a charge are read. No more admirable selection, probably, could have been made; and all it is possible to urge against the list is that it might, with advantage, have been increased by the addition of two or three names of those who have shown ability and interest in the question to be considered.

The chief object of the Commission will, of course, be to ascertain in what particulars existing arrangements for the accommodation of infectious patients are defective, and how far modification will serve to render them more effective. A difficult task this must of necessity be: conflicting interests will each require to be separately weighed, and already there is proof that strenuous attempts will be made to induce the commissioners to side with the abolitionists, if we may so term the committees whose aim it is to sweep away intra-urban hospitals. One local committee is engaged in preparing evidence with a view to this end, and has lodged an application to be heard through its representatives. It is by no means unlikely, we should imagine, that the plan so often insisted on in these columns, whereby infectious hospitals may be safely located outside of towns, and in situations permitting absolute isolation, will meet with approval from the Commission. In any case it can hardly be that further sanction will be accorded to the existence of such danger-spreading centres within the limits of cities, thereby enhancing the chances of infection already sufficiently great without such addition. Dr. Richardson's suggestion for isolating fever and small-pox patients in specially constructed buildings placed in the midst of other dwellings, though, as he described it in his paper before the Social Science Association, possessing very many important and obvious advantages over the present system, is yet surrounded by the possibility of dangers which, to the timid, would fatally bar its acceptance. One point, however, that Dr. Richardson specially insists on, viz., registration and immediate isolation of infectious cases, is bound, sooner or later, to be an essential provision of the law regulating the imperial sanitary service. We presume this will be quite within the province of the Commission to consider, even though the strict letter of the object for which it is created, is to receive evidence as to fever hospitals, and to report on the subject. Whatever may be the outcome of the Commission, however, we feel assured that much-needed radical improvements in the arrangements for receiving fever and other infectious patients will result from it, and the relief will not be provided before it is urgently required.

THE ST. BARTHOLOMEWS' HOSPITAL INQUIRY.

In our last issue we ventured to impress upon our readers the peculiar need of reserving their judgment on an issue raised through a medical man and supported by another practitioner, by way of complaint against the treatment of an inmate (himself a surgeon) in St. Bartholomew's Hospital.

The statement of complaint by a Dr. Sherrard, and the

corroboration of that complaint by a Dr. Cassidy, had occupied the entire time of the court at its first sitting. The hospital had to suffer the severe hardship of a week's interval before one word in its defence could be spoken. Its legal representative, Mr Cross, had indeed significantly intimated at the rising of the court, that a different complexion would be put upon the case when the defence was heard, but this did little to retard popular opinion from arriving at sage and final conclusions. For the few who suspected the complainants on the principle of the "sullied nest," and the "bad birds," crowds regarded them at their own valuation, as self sacrificing reformers, who at any cost to themselves, protested against, and exposed, a gross, an inhuman, a diabolical abuse. Others were willing to admit the hospital plea "not so bad as we seem," but even these more merciful judges not satisfied with damning the hospital with such faint praise, ominously quoted the popular fallacy "no smoke without fire."

Our tone was in no way undecided, yet it is to be honestly confessed, the revelations of the further sitting now held, and the position accepted by the so-called defendants have fairly startled us.

We predicted that exaggeration could be testified to. We heard the diagnosis of the previous attendants had been disputed by the hospital authorities, Drs. Smith and Duckworth, and negatived by the autopsy; but we repeat we were startled to learn that the facts deposed to throughout the first day's hearing, were by a monotonous corroboration of Dr. Smith's evidence by Dr. Duckworth and everyone of the hospital representatives, challenged as complete fabrications, and on oath deposed to as such.

Practically, they deny being defendants by raising a cross issue, in which they charge their assailants with incompetence in their professional treatment, ignorance in their diagnosis, and perjury in their testimony.

The jury cannot escape a verdict final and uncompromising. Either this is indeed a case of smoke without fire, or the entire staff of St. Bartholomew's Hospital engaged, have conspired to shield the institution attacked, at the expense of their oaths, and have been aided and abetted by the independent medical witness, retained by the court to make the autopsy, and on it and the evidence to form and express his opinions and convictions upon the points in dispute. We neither prejudice nor express an opinion upon the matter of the verdict when we record as we now do, without comment, an outline of the incidents which filled the second sitting. We advisedly postpone our comments until the jury shall have to day pronounced its verdict. Dr. Montray was selected by the court, to make an impartial and complete autopsy, and to listen as an expert, to the entire testimony, with a view to the expression of his opinions or convictions at its close. He alone is able to speak of the post-mortem appearances, and of the evidence, as a qualified and independent observer; we shall therefore be happy to place our columns at the disposal of this gentleman for the publication of the case as it came under his notice. Such details will have weight, and they are obviously due both to the profession and the public, who are alike interested in such an inquiry. How Dr. Montray justified his selection for this heavy and trying responsibility, is best

evidenced by the fact that, throughout an entire hour on Wednesday last, he gave evidence without being once challenged or interrupted by either of the sides between whom he was called on to arbitrate. It was with evident reluctance and pain he revealed circumstances to a large jury, far from creditable to his profession as represented by some of its members present. It was with still more visible pain he administered a scathing denunciation of some of the positions accepted, when the court had over-ruled his request to be silent on other points than post-mortem appearances, and when his allusion to these in general terms had been objected to by the coroner, notwithstanding his appeal. On behalf of the jury's time (with possibly a wish to spare the *then* weaker side), the evidence was as frank as it was severe, and while every term was explained to the jury, who listened with eager attention, every opinion expressed was defended by the witness, apparently to the satisfaction of his opponents, as no single statement was challenged.

At the conclusion of his evidence, both Dr. Sherrard and Dr. Cassidy declared further testimony needless. The latter joined the majority present in feeling the charge disposed of, and fit only for withdrawal but with a perseverance worthy the best of causes, Dr. Sherrard retained as much of the complaint as was possible, viz., the charge of accelerated death by hospital neglect, though Dr. Cassidy appealed to him to withdraw it *in toto*.

The Court was crowded. A large proportion of the audience were medical students of the hospital. It was evident their *esprit de corps* made the charges personal, and the satisfaction with which they received the many refutations forthcoming was natural. Their obedience to a dignified and kindly request for perfect neutrality, made by the coroner, speaks equally for the official's tact, and "the boys'" sense of fair play and discretion.

Notes on Current Topics.

Excision of Cancerous Uterus.

MR. SPENCER WELLS communicated to the Royal Medico-Chirurgical Society on Tuesday, the 22nd inst., an account of a case in which he had successfully removed the gravid uterus from a woman suffering from cancer of that organ. This, which is with justice to be regarded as a pronounced triumph of modern surgery, can safely be said to have been rendered possible only by the aid of experience, and facts learned through long series of experimental researches; and although it remains to be seen how far permanent benefit accrues from the operation, it still remains that abdominal surgery is now so far advanced that such an apparently impossible proceeding as total extirpation of the gravid uterus ranks among the attempts successfully made to alleviate human suffering by adopting an extreme and radical measure. It is not to be expected, of course, that the operation will immediately become a common or a favourite one, and a fear may perhaps be expressed lest some more daring surgeons should hasten to perform it under the sanction thus given by Mr. Spencer Wells. All such eager spirits will do well to remember that successful under-

takings of the kind included under operations on the viscera, by direct incision through the parietes, are to be expected only from those who bring to them the judgment, experience, and knowledge that constitute the only claim properly describable as "special." And, further, in the case of cancer of the uterus it should not be forgotten that only the smallest number of instances of this disease are actually more than affections of the cervix, in which the only legitimate remedies are applicable per vaginam. No reflection, however, of this kind can take away from the achievement which is Mr. Spencer Wells' latest claim on the gratitude of humanity; it is possible that he has by it opened up prospects of at least a little life to numberless doomed women, who, but for his endeavours to relieve them, might have perished unassisted. And regarded from any point of view, the success of the operation has proved most convincingly the possibilities open to the future of abdominal surgery.

The Royal Irish University and the Q.U.I.—A Difficulty. The Coming Matriculation Examination.

THE first matriculation examination under the Royal University of Ireland will be held on the 6th prox., and four following days. Long after the constitution of the Senate, under the Royal Charter, the authorities of the Queen's University applied to the Government, and obtained permission to postpone the dissolution of the Queen's University to next April, so that the Royal University and the Queen's University will exist co-ordinately, or rather independently, for the next few months. The practical effect of this permission is that all the students of the three Queen's Colleges matriculate, as heretofore, last month in the Queen's University without submission to the forthcoming Matriculation Examination next month in the Royal.

This exemption excludes some 300 or more students—the collegiate muster on the books of the Queen's Colleges being about 1,000—from the impending examination, all the rest of the candidates being from other colleges and schools. These candidates, including about thirty young women who have given notice of their intention to attend the Matriculation Examinations, amounting to over 740.

The *Irish Times* says that an important question, seemingly purely legal, but mainly one of equity, arises owing to the unexpected postponement till next April of the dissolution of the Queen's University. About 300 students, as we have said, passed the matriculation examination last month in the Queen's Colleges—that is, in the Queen's University. Will these be eligible to compete for scholarships next January with the 700 candidates, more or less, who may matriculate next month under the Royal. In the scheme submitted to Parliament and the Government these twelve scholarships of £50 a year for three years, "will be open to all students who, at the matriculation next preceding the Scholarship Examination, shall have gained honours." Some suppose that these terms preclude from competition all students save those who may matriculate and obtain honours at the examination under the Royal next month. It is said that the Queen's College authorities and students will submit the question for the opinion of counsel, and that the case, like the Supplemental Charter of 1866, may go the Queen's Bench.

Memorials of Broca.

By the generosity of the widow of the late M. Broca, the eminent French anthropologist, a prize has been instituted, to be awarded by the Society of Anthropology, of Paris for researches bearing on the subjects with which the name of Broca is inseparably associated. The last work undertaken by the deceased savant is completed in the current number of the *Revue d'Anthropologie*, edited by Dr. Topinard. The subject of this paper is "Torsion of the Humerus," and it includes a complete description of the *tropometer*, an instrument for determining the torsion of bones. Tables compiled by Broca, with the assistance of M. L. Manouvrier, and relating to the angles of torsion of the humerus in man and other animals, are given in the work, and consideration of all the facts gathered in it led to the conclusion that torsion attains its greatest amount in man, but in the case of the negro its condition is intermediate between the more highly developed races and anthropoid men, a not unexpected deduction. Some Oceanic tribes are described as being inferior to negroes, in the same way, and the transition from the human being to the larger anthropoids is an insensible one. The smallest angle observed in man is less than the smallest angle, however, observed in sixteen humeri of gorillas, a fact which does not invalidate the general law enumerated above, for this is exemplified in the fact that comparison of the gorilla with other large anthropoids yields a larger angle for the former, while the latter again possess a greater angle than that ascribed to smaller monkeys. Insensible gradations again mark the passage to carnivorous animals; and one curious fact elicited by a large number of examinations is that the angle is all but invariably greater in the left humerus than it is in the right.

Death of Mr. Gore, F.R.C.S.

THE Bath papers of a recent date contain a lengthy account of the late Richard Thomas Gore, F.R.C.S., who died on November 14, at the ripe old age of eighty-two years. Mr. Gore occupied an honourable and prominent position among the medical men of his generation, and, for many years he was intimately associated with the Bath United Hospital, being elected surgeon to it in 1844, and ceasing his connection with it but a few weeks before his decease. His medical education was carried out at St. Bartholomew's Hospital, and in 1821 he obtained the membership of the Royal College of Surgeons. He at once commenced practice in Bath, where he remained throughout a long and useful life, respected by all, and loved by every intimate acquaintance. Mr. Gore was a refined scholar, and possessed an extensive acquaintance with biological science, comparative anatomy having always been a favourite study with him. It is related that the Chair of Comparative Anatomy in University College, London, was at one time offered to him, but that he declined to accept it. Mr. Gore spent an active and useful life, and though we do not possess a considerable list of literary productions from him, he leaves behind that best testimony of a well spent existence, popular regret, and universal regard.

Fatal Street Accident to a Physician.

ON Saturday, the 12th inst., an inquest was held at St. Bartholomew's Hospital into the cause of death of Dr. Samuel Maitland Headaway, æt. 76, of 5 Dean Street, Park Lane, an Inspector-General of Hospitals. The body having been identified by Captain Headaway, of Newbridge, Ireland, as that of his father, evidence was given showing that on Monday week the deceased gentleman was proceeding along Threadneedle Street, at its narrowest part, when, to avoid the crowd on the pavement, he attempted to pass them by walking on the kerb. Suddenly his foot slipped into the road, and before he could regain the pavement it was crushed between the kerbstone and the wheel of a van. The deceased was promptly taken to a local surgery, thence to the hospital, but died from shock to the system, the result of the injuries received. He entirely exonerated the driver from all blame, and the jury, therefore, returned a verdict of "accidental death."

Linacre Chair of Physiology, Oxford.

THE Linacre Chair of Physiology in the University of Oxford, rendered vacant by the lamented death of Professor Rolleston, M.D., F.R.S., was on Saturday again filled up by the election of Mr. H. N. Moseley, Assistant Registrar of London University. Professor Moseley first achieved a general reputation in the scientific world by the publication of his inimitable researches on the anatomy of the obscure worm-like articulate *peripatus capensis*, and subsequently the whole reading public became acquainted with him as one of the eminent naturalists on board the *Challenger* during the last round-the-world exploring voyage. On returning from this journey, Exeter College, Oxford recognised Mr. Moseley's vast services to science, by electing him to a valuable fellowship tenable for five years, and since his return to England he has been chiefly engaged in work connected with the *Challenger* voyage. Mr. Moseley will make an admirable Linacre professor.

Doctors in Scandinavia.

IN his delightful work, "The Land of the Midnight Sun," M. Paul du Chailu speaks of the high esteem in which medical men are held by the people of Scandinavia, and describes the neatness and refinement which he observed in their homes even in remote country districts. Throughout Scandinavia there are *distrikts lægs* (doctors of a district), who receive yearly a certain amount of remuneration from the State, varying according to places; for the population is so scattered that, were it not so large tracts of country would be left without medical help, for doctors could not make a living. The fees they receive are regulated by law according to the distance travelled from their residences. Hard indeed, is the life of country doctors, especially of those whose districts are on the fjords or by the sea-coast. The only way of locomotion they have is by boat. Often they have to sail or row some twenty or thirty miles or even more, and encounter all sorts of weather, and great praise is due to them for the lives of self-denial they lead. There is a health officer for each province, besides one for each parish or district, and the former are especially charged

to look after the public health and take precautions necessary to prevent the spread of epidemic diseases.

Women Doctors in France.

FROM the Faculty of Paris, Madame Perrée, aged thirty-two, has recently obtained a doctor's decree. It is stated that she is only the second lady-doctor authorised to practise in France. After being successfully treated by an American "doctress" in a severe illness she was induced to undertake the study of medicine with a view of entering the profession.

Fees for Medical Evidence.

At the Bloomsbury County Court this week, the case of Whiteford v. Fitzgerald was heard, in which a medical man sued the defendant to recover the sum of two guineas for professional services rendered as a witness in a case in which the defendant recovered £18 for having one of his ribs fractured, and in which case the plaintiff gave medical evidence. After the plaintiff had stated his case, the learned judge said the claim could not be allowed, whether the plaintiff attended on subpoena or at the simple request of the defendant. His honour was then informed that after action was brought the defendant's solicitor had sent the plaintiff a postal order for one guinea. In the case of Whiteford v. Smith, heard in this Court in 1878, his honour had allowed the same plaintiff two guineas for his attendance at the police court for similar evidence. His honour, however, ruled that the plaintiff in the present instance was not entitled to recover.

The Medical Acts Commission

MET at 2 Victoria Street, Westminster, on the 18th, 19th, and 21st inst. Evidence was taken from Dr. Quain, and from Mr. F. W. Crick (Medical Herbalists' Association) (!!!). Present:—The Earl of Camperdown (chairman), the Bishop of Peterborough, the Right Hon. W. H. F. Cogan, the Master of the Rolls, the Right Hon. G. Sclater-Booth, M.P., Sir William Jenner, Mr. Simon, C.B., Professor Huxley, Dr. McDonnell, Professor Turner, and Mr. John White (secretary).

Deaths amongst Medical Foreigners.

DR. HOLLAND, the talented editor of Scribner's monthly, died very suddenly on October 10th. He was educated as a doctor, and practised medicine some three years. There can be no question that this education greatly modified his writings and his lectures. He was one of the most prolific writers of this century.

Dr. W. W. Greene, Professor of Surgery in the Medical College of Maine, U.S., died at sea on his return from the late International Congress at London. He at one time occupied the chair of surgery at the University of Michigan, and at the Long Island Hospital Medical College.

Dr. Crowe, Professor of Obstetrics in the University of Louisville, died on September 27th, very suddenly. He was in his fifty-third year. He was supposed to have died of oedema of the glottis.

Dr. Howard was drowned at Baltimore on September

5th. It is supposed that he fell overboard from a tug during an attack of uræmic apoplexy.

Dr. Otto Spiegelberg, late Professor of Midwifery in the University of Breslau, died on August 10th, from renal disease, at the age of fifty-two. He was well known for his writings on obstetrical subjects, and especially for his text-book on midwifery. As an ovariologist he had considerable reputation.

Poison Vending by Deputy.

A SOMEWHAT important decision was recently given in an appeal case brought by the Secretary of the Chemists' and Druggists' Association, in order to have the law declared as to whether a trader can sell by retail poisons supplied to him by a duly qualified chemist and druggist, under cover of a label bearing the name and address of the chemist, and not of the actual vendor. In this case, a grocer at Oxford had received packets of drugs from a chemist to sell for him on commission. The magistrates would not convict him, but referred it to the Court whether the sale was legal, and whether the packet was duly labelled. It was decided that the magistrates had not drawn the proper inference from the facts as to the sale, and that the packet was not duly labelled within the Act. In the present case it was clear that the chemist who first sent the poison to the defendant could not be deemed the seller of the packet of poison, as he was not on the premises, and was not, therefore, in a position to comply with the Act. The person who sold poisons was to enter the names of purchasers in his books, and a person living at a distance could not do so.

Fever in India.

A GREAT increase of a malarious fever of the most virulent type is reported to have broken out in certain districts of Lower Bengal. Opinions differ, as they usually do, as to the cause of the outbreak; but one which finds most favour is that which attributes it to the obstruction of drainage of the country by the road and railway embankments. The Lieutenant-Governor of the province, accepting this view, has made a grant of Rs. 50,000 for the purpose of constructing culverts and improving the drainage. Extra medical aid has been sent to the affected districts; and, as a matter of course in India, a committee has been appointed to report on the whole subject. On this occasion a medical officer has actually been appointed president of that committee. Dr. Lidderdale is placed at its head—we may therefore expect a valuable report by-and-by.

The latest returns from Umritsur show that the mortality from choleraic fever in that city is rapidly diminishing. The improvement is believed in a great measure to be due to the opening of soup kitchens, and the distribution of wholesome food among the poorer classes.

A FEW days since, Dr. Yeld, medical officer for the borough of Sunderland, committed suicide at his residence in that town. He had held office about eight years, and was highly respected. The deceased had been in a desponding frame of mind lately. He was in his 74th year, and leaves a widow and three daughters.

Angina and Albuminuria.

At a recent meeting of the Société Médicale des Hôpitaux, M. Lereboullet read a report on a "memoir" by Dr. Laure, of Lyons, on the relations of angina with albuminuria. We know that in rheumatism, the albuminuria depends on a slight congestive nephritis, and that the nephritis is more severe in gout. M. Laure basing his opinion on several observations of rheumatism with angina and severe albuminuria, attributes to the angina the most part in the production of the albuminuria. He seeks also to establish the fact that in the course of any angina, even catarrhal, we find albumen in greater or less quantity in the urine, albuminuria which may at length become permanent. M. Lereboullet does not entirely agree with this opinion, and does not think that albuminuria is so common in various anginae. The cases which M. Laure has observed may offer some special conditions; but in presence of such a considerable albumen in rheumatic patients, 3 grammes per litre in one case, it is very probable that a pre-existing nephritis added its action to that of the actual affection. In the second place if the patients were followed up long after the cure, one would doubtless find an albuminuria independent of the rheumatism and the angina, and symptomatic of a renal lesion. This opinion is supported by the retractility of the albuminous coagulum observed by M. Laure.

Resorcin in Aural Surgery.

DR. ROSSI, of Rome, communicates to the *Archives of Otolology* a note on the use of resorcin in aural practice. This substance, a parabioxy benzole, discovered by Hlaswitz and Barth in 1864, was introduced into medical practice by Andeer in 1877. Dr. Rossi has used it in more than 300 cases of purulent middle ear inflammation, and claims that no remedy at his disposal has given such substantial results in this obstinate affection as resorcin. He has used it pure, or in aqueous or alcoholic solution, 4 in 100. He promises further records of results.

A DESPATCH from Havana announces the receipt of advices from Barbadoes, according to which the yellow fever has almost entirely disappeared from that island.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of their population, were, in—Norwich 17, Leeds 17, Bristol 17, Plymouth 18, Sheffield 18, Bradford 19, Birmingham 19, Leicester 19, London 19, Oldham 19, Newcastle-on-Tyne 20, Dublin 21, Edinburgh 21, Wolverhampton 21, Portsmouth 21, Nottingham 22, Glasgow 22, Manchester 23, Salford 23, Sunderland 24, Brighton 25, Liverpool 26, Hull 27.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 26, Bombay 28, Madras 36, Paris 27, Geneva 17, Amsterdam 23, Rotterdam 21, The Hague 19, Copenhagen 20, Stockholm 15, Christiania 18, St. Petersburg 40, Berlin 21, Hamburg 21, Dresden 26, Breslau 32,

Munich 26, Vienna 26, Prague 24, Buda-Pesth 29, Naples 28, Venice 21, Alexandria 30, New York 29, Brooklyn 22, Philadelphia 20, and Baltimore 27. No returns were received from Brussels, Lisbon, Rome and Turin.

FROM diseases of the zymotic class last week in the large towns, the death-rates per 1,000 from scarlet fever were 13.8 in Hull, 4.4 in Nottingham, 2.7 in Edinburgh, and 2.4 in Brighton; from measles, 3.1 in Liverpool, and 1.7 in Manchester; and from "fever" 1.2 in Portsmouth, and 1.0 in Brighton. The 39 deaths from diphtheria included 15 in London, 12 in Glasgow, and 6 in Portsmouth. In Hull 41 more fatal cases of scarlet fever were recorded, making no fewer than 470 that have been recorded since the beginning of July. The 11 deaths from measles in Manchester included 10 in the Crumppall Workhouse. Small-pox caused 14 more deaths in London and its outer ring of suburban districts, and 2 in Salford; no fatal case of this disease was registered in any of the other large towns.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

ILLEGITIMATE BIRTHS IN SCOTLAND.—The return of the Registrar-General of the births, deaths, and marriages registered in the divisions, counties, and districts of Scotland for the quarter ending 30th September, contains some curious information. In the North-eastern divisions the illegitimate births were 14.6 per cent.; in the counties of Nairn, Elgin, Banff and Aberdeen, they were respectively 15.15, 18.8, 18.8 per cent. These are just the parts of Scotland from which Dr. Begg, Principal Rainey, and other shining lights of the free church, draw their majorities in crushing Dr. Robertson Smith, and other heretics. There seems to be some occult relationship between great religious fervour and morality of a very questionable kind.

THE ABERDEEN MILK EPIDEMIC.—The good people of Aberdeen do not appear at all satisfied with the report issued by the inspectors appointed by the Board of Supervision. Matters, as we pointed out at the time, were not improved by the report, and the Aberdonians have had to pay pretty heavily for being told, in official language, what they knew all about before the Commission investigated the matter. There are inherent difficulties doubtless in the case which, it does not appear, further discussion or investigation would clear up. A memorial, however, signed by a large number of those who suffered from the epidemic, and by the Presidents of the Aberdeen, Banff, and Kincardine Branch of the British Medical Association, and the Aberdeen Medico-Chirurgical Society, has been presented to the Home Secretary, praying for an additional investigation into the causes.

THE ANATOMY CLASS IN THE EDINBURGH UNIVERSITY.—The practical anatomy class in the University numbers 700 students, to teach which there is one professor, and two or three demonstrators. The students cannot complain of over-supervision. If the Professor were not an examiner, students would scarcely submit to the chances of seeing a demonstrator once a fortnight, and the Professor by accident.

THE HEALTH OF EDINBURGH.—At a meeting of the Public Health Committee of the Edinburgh Town Council, held on

the 22nd. inst. Dr. Littlejohn submitted his report on the health of the City for the month of October. The report showed that 368 deaths had been registered during that period, giving a rate of 18.90 per 1,000 per annum. The average rate for October in the five preceding years was 17.80, so that the rate for last month is considerably above the average. There were 125 deaths, or 17.58 per 1,000 recorded in the new town; 213, or 23.11 in the old town; and 30, or 11.08 in the southern suburbs. 99 deaths were due to diseases of the chest, 43 to debility and age, and 48 to zymotic diseases. Half of the zymotic cases were scarlatina, and no fatal case was reported from the southern suburbs. 648 births were registered, giving a rate of 33.85 per 1,000; of these, 325 were males, and 318 females—58 were illegitimate. During the month 313 cases of infectious disease was reported, in terms of the 208th section of the Edinburgh Municipal and Police Act. These comprised 245 cases of scarlatina, 19 of measles, 43 of typhoid fever, 8 of diththeria, 1 of syphus fever, and one of small-pox. Of the cases of scarlatina, 112 occurred in the new town, 109 in the old town, and 20 in the southern suburbs; while of the typhoid fever cases 15 occurred in the new town, 23 in the old town, and 5 in the southern suburbs. The Committee had before them several cases of insanitary houses, and the usual instructions were given to the clerk with regard to communicating with the proprietors. The Committee had also under consideration the propriety of adopting more stringent measures with reference to the inspection of newly-erected houses, so as to ensure that they were in a fit state before certificates were granted.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday the 19th inst., were at the rate of 23 per 1,000, against 23 in the preceding week, and 21, 22, and 23 in the corresponding periods of 1880, 1879, and 1878.

OUTBREAK OF MEASLES AT CARDONALD, NEAR GLASGOW.—There are upwards of 100 children enrolled at Cardinal School, and out of that number only forty-two were present recently, in consequence of the alarming outbreak of measles in the neighbourhood.

SIR WYVILLE THOMSON.—The resignation of Sir Wyville Thomson of the Chair of Natural History in the University of Edinburgh has been at last officially notified to the Senatus Academicus. This step had been expected some months past, and the resignation was announced in several journals more than a month since, but subsequently withdrawn as premature. We regret to learn that continued ill health is the cause of the learned professor's relinquishment of his duties at the University, and trust that rest and retirement will bring about a speedy restoration.

THE FELLOWSHIPS OF THE ROYAL IRISH UNIVERSITY.

It will be recollected that under the University scheme as approved by Her Majesty, a considerable number—we believe twenty—of Fellowships are to be created, of which the Senate are to select the occupants. These appointments will be worth £400 a year each, and—so far as has yet been determined—will be sinecures, so that it will be readily believed that the number of appointments for these desirable distinctions are numerous. We understand that the selection of Fellows will probably not be made until February, and it is generally understood that the Professors of the Queen's Colleges who have, to a certain extent, been discredited by the establishment of

the new University, will receive the largest share in these appointments, and that part of their duty as Fellows will be to act as Examiners. Upon all these matters, however, the strictest secrecy is observed, and nothing authentic is known as to the intentions of the Senate.

THE SURGICAL SOCIETY OF IRELAND.

THE opening meeting for the Session 1881-82 took place on Friday last in the College of Surgeons, the Chair being occupied by the President of the College, Dr. Chaplin. The attendance of members and visitors was very large. The inaugural address of the President was devoted chiefly to an interesting review of the practical operation of the Contagious Diseases Act, which he had special opportunities for observing in his capacity of visiting surgeon to the Lock Hospital at Kildare, for the Curragh district. The address was followed by a narrative by Mr. Wheeler, on a case of nerve stretching for the cure of tetanus, which had been followed by immediate relief, and the reading of the paper was followed by an interesting debate. After the adjournment of the Society, the President entertained the Council of the Society and a number of visitors at supper in the College.

Correspondence.

THE NOTIFICATION OF INFECTIOUS DISEASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—When this subject was recently under debate in the Public Health Section of the Social Science Congress I actively opposed the introduction of the proposed system into Ireland, on the ground that to compel the physician to send to the sanitary authority notice of every infected case would cause him in many instances, to be excluded from the sick house, and thus inflict incalculable loss and inconvenience both on him and on the patient. Although I quoted the public confession of the Public Health Committee, that the limited system of notification which exists in Dublin does actually produce the result which I foretold, yet I was contradicted by Mr. Hastings, M.P., Mr. Gray, M.P., and others, and it was positively asserted by them that in English towns where infectious diseases were compulsorily notified no such inconvenience ever resulted, and moreover, that both medical profession and the public in these towns, having found the system satisfactory in every sense, highly approved of it and cordially administered it. Let us see whether these assertions are true or not? The model towns selected by the champions of compulsory notification are Edinburgh and Bolton, and the great guns which they brought to bear against my argument were Drs. Littlejohn and Sergeant, the medical officers of health of those two places. Within this week the attitude of the medical profession towards the notification system was clearly manifested in Edinburgh and in Bolton. In Edinburgh a Dr. Bowie was prosecuted for not notifying to Dr. Littlejohn an alleged case of typhoid fever. From the report of the proceedings in the *Medical Press*, of the 16th, it appears that Dr. Littlejohn, having been informed by a private letter that Dr. Bowie was attending a case of typhoid fever, sent a policeman to ascertain the nature of the case. How the policeman diagnosed the case, whether he entered the sick room and examined the patient for the characteristic typhoid eruption on his or her body does not appear, but at any rate on the report of this policeman Dr. Bowie was prosecuted. Dr. Littlejohn admitted in court that he had not seen the patient at all until the day of trial, a week after the accusation was lodged by the policeman. Are these, then, the blessings which Mr. Gray promises the citizens of Dublin if they accept his bill? Are the public expected to rejoice over the prospect of a diagnostic visit from the sanitary policeman of the Corporation? and are the

medical profession to be considered obstructive, because they object to have their diagnosis reviewed by such an authority, and themselves subjected to prosecution if their opinion of the signs of typhoid fever does not happen to agree with that of the policeman. In Bolton, again—the land of “utter” sanitarianism and self-immolating doctors—it appears that the result of five years’ experience of the working of the notification system has been to disgust the medical profession with it. The fact that the English Notification Bill of last session was stopped by Mr. Thomassen, the representative of the town where the system is in its pure delight, would be a sufficient cause for suspecting the law of compulsory notification is not altogether so beneficent as it has been pourtrayed, but the proceedings of a recent meeting of the Lancashire Branch of the British Medical Association takes the blush off the rose-coloured accounts of Bolton given by Mr. Gray and his supporters. At this meeting Mr. Sergeant, the medical officer of health for the town, read an elaborate eulogy on the notification system, but instead of the chorus of approval which Mr. Gray would lead us to expect, the communication was met by a storm of dissent. Time did not allow of half the abuse heaped on the system by the physicians present, and eventually a hostile vote was barely avoided by the ruling of the chairman that it was not in order to move resolutions upon the reading of a paper. Sir, I ask your readers are these illustrations of the notification system such as to reconcile either the public or the physicians to Mr. Gray’s bill? If my statements cannot be impugned—and I believe they cannot—they prove, I think, that the advocates of compulsory notification have painted a picture to suit their own argument, and that the citizens of Dublin and the medical profession in Ireland ought to think very seriously before they have the sanitary persecutions of Edinburgh, or the endless squabbles which seem to be current at Bolton.

Yours, &c.,

ARCHIBALD H. JACOB, M.D., F.R.C.S.I.

23 Ely Place.

Literature.

A TREATISE ON ORTHOPÆDIC SURGERY. (a)

MR. HAWARD prefaces his work with the question as to how far surgery has been benefited by its subdivision into so many special fields, and he goes on to remark that though in some cases the results may have been an increase of knowledge, yet that an exclusive devotion to one part of surgery is apt to interfere with a just appreciation of the proportion which that part bears to the whole. Heartily do we endorse this sentiment, and clearly will we say that in our opinion, if orthopædic surgery is to be practised as a special art, it should be undertaken by those whose skill in general surgery has been approved, and whose judgment has been tempered by practical experience. Before looking into the book we may say that Mr. Haward’s position is one that will entitle him to speak and to be attended to in the question of orthopædic surgery, for he is surgeon to a general hospital, where he is also entrusted with the care of that special department. Moreover, he was for some years on the surgical staff of the Great Ormond Street Hospital for Children.

The first chapter treats of the various forms of talipes, and is illustrated by woodcuts, which, though a little rough, are likely to be of great value to the student. The description of the operation of tenotomy for the talipes is clearly written and carefully explained. The specious claim held forth by those who would cure club-foot without tenotomy is condemned, and it is advised that the treatment of congenital deformity be undertaken in the healthy child at the third month. As regards the accidental division of the artery along with that of the posterior tibial tendon the author is very honest. He says, “The hæmorrhage will be controlled by a pad and bandage, and I have never seen any harm result, though, of course, every care should be taken.” To affirm that one has operated often for club-foot and that he has never cut the large artery, is suggestive neither of surgical veracity nor anatomical knowledge.

(a) “A Treatise on Orthopædic Surgery.” By J. Warrington Haward, F.R.C.S. London: Longmans, Green, & Co. 1881.

When dealing with the subject of talipes which follows on infantile paralysis, he points out the need of taking precautionary measures against the occurrence of the deformity, and of promoting the nutrition of the limb by friction, passive exercise, and warm clothing. Of the service rendered by galvanism he has no firm belief, though he has watched many cases in which it has been systematically and perseveringly practised for long periods. He regards it as one among other efficient stimuli, but inferior in therapeutic value to friction. This definite expression of opinion is of considerable value, and coinciding as it does exactly with our own experience and teaching, we venture to direct especial attention to it.

The first chapter, which consists of 52 pages, ends with the judicious advice that each individual case be thoroughly examined before any treatment is suggested, for similar deformities are produced by various causes, and each will be found to give special indications.

The chapter upon wry-neck is too short to be entirely satisfactory: three lines quoted from Dr. Little hardly do justice to the question of the association existing between the sterno-mastoid tumour of early infancy and subsequent permanent contraction of the muscle. A lingering and instrumental labour, or a breech presentation, is frequently the cause of rupture of the sterno-mastoid muscle, and the contracting cicatricial tissue which fills in the gap forms, in our opinion, at least, a frequent prelude to wry-neck. The subject of cervical deformity, the result of vertebral caries, also demands at Mr. Haward’s hands, a fuller clinical description than it has received.

The author regards the contraction of the finger upon the palm as a manifestation of the gouty diathesis, but admits that in some cases, neither constitutional nor local cause for the deformity can be discovered.

In speaking of congenital dislocation of the hip, it might have been well if attention had been called to the close resemblance to this condition, which is presented by certain cases of rachitic deformity, though when the author remarks that in the former condition the upper border of the great trochanter is above the level of Nélaton’s line, he gives the diagnostic sign of the congenital displacement.

For ingrowing toe-nail, the treatment suggested consists in the elevation of the edge of the nail by the flexible lead plate.

Rickets (p. 90), is described as being “essentially a debility,” so that a surgeon, “taking the mechanical and restricted view, which would look upon rickets merely as a disease of the bones, requiring only appropriate instruments to remedy their distortions,” will but partially succeed. Indeed, it would be well in these days, when so many of us are affected with what the French surgeon called “*pruritus secundæ*,” if one appreciated the truth of Mr. Haward’s statement, that, “while the bones are capable of being bent, they also admit of being straightened.”

The entire chapter on Rickets is excellent, and full of practical remarks and suggestions. That part of the book which deals with the subject of lateral curvature of the spine is extremely clear and well written. It explains the rotation of the vertebrae as the result of uneven muscular contractions, in a weak and lolling patient, and in the last paragraph of page 134, the author explains the unsymmetrical condition of the vertebral segment and its processes in the same manner as he deals with the deformity of the femoral condyles in an extreme case of knock-knee. One anticipates what line of treatment for cases of lateral curvature Mr. Haward is going to prescribe, when he says “the spinal curvature is only a part of a general debility.” Nor is one disappointed, for a few pages on he writes, “that the treatment is so obvious that he will content himself with saying only, that it should not be a ‘spinal’ instrument.” Moreover, (p. 155) if the explanation which I have given of the origin of lateral curvature be correct, it must follow that the merely mechanical treatment of the distortion is an error.” Rest during the greater part of the day on an appropriate couch, short periods of gymnastics, or some other suitable exercise in the open air; cold or tepid douches, are the therapeutic agencies in which he places most reliance.

We are surprised to find that the important subject of spinal caries and angular deformity finds no place in Mr. Haward’s “Treatise on Deformities;” true, he mentions it as a cause of wry-neck, but the only other reference to it is (p. 158), where he says that in its treatment he has now

given up the plaster of Paris jacket. Nothing is said in connection with the treatment of talipes by plaster of Paris rollers, but the omission leads us to infer that Mr. Haward does not approve of it. Luxation of the scapula, the result of paralysis of the serratus magnus, is another matter which has escaped attention.

In conclusion, we would say that though, as we have just remarked, Mr. Haward's treatise on orthopaedic surgery has its errors, they are those of omission rather than of commission. In other words, we are so pleased with his work that we wish there had been more of it. We feel sure that it meets a real need: it is practical, and is, moreover, charmingly free of *ad captandum* jingle or mystery. We do not find even the illustrations of splints, or other apparatus, described as "the author's," or "modified by the author." The author is, on the other hand, careful to give others due credit for their material which he has used, and for their ideas which harmonise with his own. We predict for the book an extensive circulation, and we will hail the early issue of an enlarged edition with a heartiness equal to that with which we commend the present one.

The work has evidently been carefully revised, and is, in consequence, almost entirely free of errors. The type is excellent, and the paper so thick and good that we would willingly have relegated the task of cutting the leaves to the Messrs. Longmans' machine boys.

POWER ON THE ARTERIES. (a)

THE additions and improvements incorporated in the third edition of Mr. Power's well-known work on the arteries of the human body, bring it up to the present requirements of a high-class standard guide to the special anatomy of the arterial system. Its value will be chiefly for the advanced student and the surgeon as a work of reference, in which respect it is impossible to over-praise it. It includes short and historical records of the more important operations for tying the larger arteries, and gives explicit directions for actual performance of them in each case. The arrangement of the material is calculated to assist in the study of the course, relation, &c., of the vessels, but it might, perhaps, be said of it, that the introduction of tabular accounts of distribution would add to the ease of mastering its contents. By the omission of physiological details, the necessity for which, in the earlier editions, was never apparent, and the discussion of the most recent German and other researches, the volume is made more purely a work on surgical anatomy of the arteries, and in its present form is a compendious and perfect description of the subject. The publishers are to be congratulated on the elegant appearance of the volume, the typographical execution of which leaves nothing to be desired.

Novelties.

"FOSSILINE" PLASTERS.

THE plasters recently manufactured by, and introduced to the profession by Messrs. Evans and Sons, of Liverpool, under "Mason's" patent, are deserving of notice by those who are prohibited by the extravagant price of plasters spread on leather from using them in hospital work and in the general run of practice. The Fossiline Combination or Leatherine on which the plaster is spread seems to us to serve almost every purpose which leather itself fulfils.

It is extremely tough—stretches readily to the shape of the part to which it is applied—does not crack, and is entirely impervious to water. With these qualities it combines the special merit of cheapness, and—as it can be bought at very much less than the leather or swansdown plasters—we anticipate that it will supersede the more expensive articles for the general run of surgical work. Having practically tested these plasters, we would add that if further experience of their use should justify the favourable opinion formed from first use, the "Fossiline" Plaster will be a valuable addition to the surgeons' stock of requisites.

(a) "Anatomy of the Arteries of the Human Body." By J. H. Power, F.R.C.S.I. Third Edition. By W. Thompson. 1881. Dublin: Fannin and Co.

A PORTABLE BATH FOR WARD AND PRIVATE USE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you permit us to draw the attention of the profession to a hospital bath we are about to introduce. This bath is 5ft. 6in. long, and made of strong tinned iron, japanned in and out, fitted with a large draw-off tap, and

drainer-plate over same; is mounted on a wood bottom, on iron wheels with india-rubber tyres, to be noiseless for ward use. This bath is being now used in a house where there is scarlet fever, and as this disease is very prevalent just now, and the fever hospitals are re-opening, we humbly think our new bath will meet a want.

Your obedient servants,

J. ALLEN & SON, Manufacturers.

21 and 23 Marylebone Lane, London.

Royal College of Surgeons of England.—The following candidates for the diploma of M.R.C.S., having passed the required examinations were admitted Members of the College on November 17th:—

Booth, George
Foxwell, William Arthur
Gardner, Percy H.
Green, Edwin Collier
Grimsdale, Thomas B.
Johnston, Thomas
Knight, Alfred Osborne

Lothouse, Arthur, L.S.A.
Morton, Charles Alexander
Pook, William John, L.S.A.
Stonham, Charles
Stretton, John Lionel
Walker, Francis John

The following were admitted Members on Nov. 18th:—

Bisall, Austin Charles
Campbell, Harry
Colville, Ernest George
Cooper, George Frederick
Giles, Oswald
Hays, James
Humphrey, Francis William
Kempster, Wm. Henry, M.D.

Longman, George Philip
Pollock, William Evers
Rackham, Arthur Richard
Sackeving, Herbert Edward
Stuart, Sidney Offord
Williams Jn. Frederick, L.S.A.
Wray, Charles

The following were admitted Members on Nov. 19th:—

Adams, William Coope
Andrews, Archibald George

Webster, George Leonard, L.S.A.

NOTICES TO CORRESPONDENTS.

"IRISH MEDICAL DIRECTORY" FOR 1882.

WE are requested to state that the sheets of the Directory will be put to press in a couple of days, and that the last moment has arrived at which any correction or addition to its pages can be accepted. Therefore, those who have not already sent alterations must do so at once.

A DISGUISED ONE.—You will see many such characters portrayed in that curious mixture of fact and satire, "Medical Men and Manners of the Nineteenth Century," a little book published a few years since, the truth of which has been but too certainly shown in some recent cases, notably the one to which you refer.

THE APOTHECARY'S FRIEND.—The following is copied from an old book:—"Died, at Beckington, aged 65 years, on May 17, 1817, Mr. Samuel Jessup, an opulent grazier of pill-taking memory. He was distinguished for the last thirty years of his life for an inordinate craving for physic, as appeared on the trial respecting the amount of an apothecary's bill. The evidence then given affords the following material for an epitaph. In twenty-one years, from 1794 to 1816, the deceased took 2,6,984 pills, supplied by a respectable apothecary at Botsford, which is at the rate of 10,800 pills a year, or 29 pills each day, but as the patient began with a more moderate appetite, and increasing it as he proceeded, in the last five years preceding 1816 he took the pills at the rate of 7 a day, and in the year 1814 he swallowed no less than 51,590. Notwithstanding this, and the addition of 40,000 bottles of mixture, julep, and electuaries, extending altogether to fifty-five closely-written columns of an apothecary's bill, the deceased lived to attain the advanced age of 64 years."

MR. W. D.—The result is eminently satisfactory, and we tender to you our best thanks.

ONE WHO TRIES TO BE HONEST.—We disapprove of the practice, and think with you that it is inconsistent with the protestation made when junior practitioners attempt to advertise themselves in a still less objectionable way. We would commend to their consideration the reply of an eminent president of a medical society who, when asked to sit for a photograph, said: "I have never been in a photographic gallery in my life, and do not intend making an exhibition of myself for shop windows; younger men appear to like it, I do not."

"QUINQUININE"

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—For the information of your correspondent respecting "Quinquinine," I beg to be allowed to say that this article was discovered and introduced by myself more than fifteen years since, and was known as "Seller's Quinquinine" long before my short connection with the firm of Mackey, and no other person possesses the exact knowledge for its production.

I still continue to manufacture the article as originally produced, and do not hold myself responsible for any preparation bearing the name of "Quinquinine" which has not my name and address on the label.

I am, dear Sir, yours faithfully,

17 Farringdon Road, London, E.C. JOHN SELLERS.

MR. ANTHONY (Colonial Office).—You will find the article on "Cyprus" by Dr. Cullen in our issue for Nov. 16th.

QUEST.—Your surmise is incorrect; the Obstetrical Society of Dublin is the oldest of the kind in the United Kingdom or America.

DR. MOOREHEAD'S paper is marked for early insertion; proof will be sent him as requested.

MR. H. W. R. will please accept our best thanks for the interest he takes in the welfare of the *Medical Press*, and for the name of another subscriber through such instrumentality.

LUNACY CERTIFICATES.—W. C. asks: Please inform me if I can recover a fee for examining a dangerous lunatic where the magistrate refuses to sign the order authorizing the Board of Guardians to pay me. The friends of the lunatic gave me a red-ticket asking me to visit and examine the patient, which I did, sending the medical certificate and form for my fee to the magistrate who refused to sign the latter on the ground that the lunatic was not discovered and apprehended under circumstances denoting a derangement of mind and a purpose of committing some crime for which, if committed, such person would be liable to be indicted, although she had attempted suicide by placing herself before a train in motion.

[You are not entitled to a fee unless the patient is actually brought before the magistrate by the police as dangerous. There is no obligation on you to certify at all, but on red-ticket—you must visit, and, if necessary, prescribe, and if you certify you cannot recover a fee.—ED.]

RETINAL HÆMORRHAGE IN ITS MARITAL ASPECT.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Would you, or some of your readers, kindly give their opinion on the following case:—

A young woman has been under treatment for some time for recurrent retinal hemorrhage. Her friends wish to know if marriage—which she contemplates—will be prejudicial or otherwise; and as I can find no reference to it in any of the authorities, I would be glad of the views of those who may have had experience in the matter, and oblige,

Yours, &c.,
"MYOSOTIS."

MR. J. DUNCAN.—Many thanks for the Turkish address.

CYPRUS.—From an advertisement in another column it will be seen that two assistant-surgeons are required for the Government Medical Establishment of Cyprus. The salary of an assistant-surgeon is, for the first year, £50; and then if the officer passes a satisfactory colloquial examination in either Turkish or Greek, £200 a-year, rising by annual increments of £10 to £200 a-year. Private practice is allowed. This information will be of interest to our correspondent, "*Chi He Aris*," whose letter appeared in our last, and to others seeking Colonial appointments.

A VOLUNTEER HOSPITAL CORPS FOR DURHAM UNIVERSITY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—For some time the idea of the formation of a Volunteer Hospital Corps has been mooted among the students of this College, and in furtherance of the project, a meeting was held on Oct. 28th, Dr. Mears presiding. A large number of the students attended, and resolutions passed appointing a committee consisting of Dr. Mears and Messrs. C. H. C. Milburn, F. W. Gibbon, and D. J. McNabb to carry the project into effect, and engaging the students to support the movement. As the committee were at first unable to see in what way the full strength of a bearer-company, on the model of the Army Hospital Corps, might be made up, although nearly sixty students had given in their names, they waited on Lieut.-Col. Potter, C.B., of the

1st Northumberland Artillery, who evinced great interest in the matter. He pointed out that there were two plans open—viz. for the Corps to be attached to a regiment such as his own, detachments being left to other regiments, or for the Corps to be independent, having for its cadre the students of the College, the strength being made up by drafts from the regiments in the district. The former plan at the time appeared the more feasible, as Col. Potter kindly undertook all negotiations with the War Office, and at the same time offered the use of the drill-hall and other advantages to the Corps. No reply has as yet been received from the War Office, but whatever it may be, there can be little doubt, from the interest taken in the matter in the district, that the movement will be ultimately successful.

I am, Sir, yours faithfully,

W. F. MEARS, M.B.

University of Durham College of Medicine,
Newcastle-on-Tyne, Nov. 27, 1881.

N. F. M.—If possible in our next.

ONE OF THE OLD SCHOOL OF DOCTORS.—Your letter will be inserted in next issue.

DISPENSARY HOUSES.—E. H. says: The committee of a dispensary district are thinking of borrowing money from the Board of Works to build a dispensary and residence for the medical officer; is there not some Act by which money can be borrowed cheaper than 5 per cent.?

[Under sec. 6 of Dispensary Houses (1879) Act, "Every loan made under the provision of this Act shall bear interest at the rate of 4 per cent. from the date of each advance to the fifth day of April the tenth day of October which shall next happen after such advance, and shall be repaid by the payment to Her Majesty of an annual rent-charge of five pounds for every one hundred pounds of such loan from time to time advanced, and so in proportion for any lesser amount, to be payable for the term of thirty-five years, to be computed from the first of the said days which shall next happen after the advance in respect of which the rent charge shall be charged.—See "Irish Med Directory," page 601.]

DR. LITTLEJOHN (Edinburgh).—Communication in type, omitted at last moment for want of space; will appear in our next.

THE SOCIETIES.

HARVEIAN SOCIETY.—Thursday, Dec. 1, at 3.30 p.m. First Harveian Lecture: Dr. Alfred Meadows, "On Menstruation and its Derangements."

Vacancies.

Bckett Hospital, Barnsley.—House Surgeon. Salary, £151, with board. Applications to the Hon. Sec. before Dec. 10.

Isle of Man Hospital.—Resident Medical Officer. Salary, £100, without board. Applications to the Secretary at Douglas, before Dec. 5.

Kent County Asylum.—Assistant Medical Officer. Salary, £130, with board. Immediate application to the Medical Superintendent. (See Advt.)

Middlesex County Lunatic Asylum.—Assistant Medical Officer in the Male Department. Salary commencing at £150, with board. Applications to be made on printed forms to be had of the Clerk. (See Advt.)

Births.

ALLEN.—Nov. 20, at Willowbank, Keady, co. Armagh, the wife of Dr. J. Gower Allen, of a son.

CLARK.—Nov. 24, at 19 Cavendish Place, London, W., the wife of Andrew Clark, F.R.C.S., of a daughter.

DRUMMOND.—Nov. 18, at 3 Piazza di Spagna, Rome, the wife of Edward Drummond, M.D., of a daughter.

HILLIARD.—Nov. 23, at Fairmead House, Upper Holloway, N., the wife of E. Harvey Hilliard, M.D., of a daughter.

MACSWINNEY.—Nov. 22, at Westall House, Brook Green, W., the wife of G. H. MacSwinney, M.D., of a daughter.

TABUTEAU.—At The Chestnuts, Fortarlington, the wife of J. M. Tabuteau, M.D., of a son.

Deaths.

CHEESBROUGH.—Nov. 20, at his residence, Blackburn, Harry A. Cheesbrough, M.D. Edin., Consulting Physician to the East Lancashire Infirmary, aged 44.

COOTE.—Nov. 17, at Ashby-de-la-Zouch, Michael Coote, M.D. M.R.C.S., aged 89.

DAVIS.—Nov. 23, at Duffryn Firwd, Mountain Ash, E. W. S. Davis, M.B.C.S., aged 63.

DAVISON.—Nov. 13, at Saffi, Morocco, Dr. Frank Davison, of Armagh, aged 29.

DENNY.—Nov. 18, at Stoke Newington Dispensary, John Denny, L.R.C.P. Ed., M.B.C.S., only son of the late John Denny, Surgeon of Ipswich, aged 62.

ERKINE.—Nov. 7, at Sandys Place, Newry, Archibald Erkinie, M.D. HAYNE.—Nov. 19, at 1 The Hill, Northfleet, Frederick Graves Hayne, M.B.C.S.E., in his 60th year.

HEAD.—Nov. 11, at the residence of his brother, the Rev. G. Q. Head, of Fishwick, Newton Abbot, Devon, Edward A. H. Head, M.B. Lond., M.R.C.P., aged 63.

TAYLOR.—Oct. 21, at Delhi, India, after a short illness, Adam Taylor, Surgeon-Major, Bengal Army.

WRIGHT.—Nov. 22, at Hollycot, Lasswade, Alexander Wright, Surgeon-General (retired), Bombay Army, aged 71.

MENSTRUATION AND ITS DERANGEMENTS.

By ALFRED MEADOWS, M.D., F.R.C.P., &c., Physician to, and Lecturer on Midwifery and Diseases of Women and Children at, St. Mary Hospital.

Abstract Report of Harveian Lectures for 1881.

THE subject selected for the Harveian Lectures of 1881 was chosen, said Dr. Meadows, after much consideration, as being that on which he felt himself most able to speak with authority. He had felt the difficulty attendant on finding a topic which might prove of general interest to the profession, but for many reasons menstruation might be regarded as being of this nature. There were also connected with it many obscure points, investigation of which would lead to the discovery of important facts, and he earnestly invited young and enthusiastic observers to devote their attention to the study of those physiological problems which in this connection offered such inviting fields of research. Every practitioner of medicine, moreover, must be nearly and deeply interested in the phenomena of menstruation, and the derangements to which the process was liable. To surgeons it was a factor of the first importance, from the influences it exerted on the condition of the body as regarded operations to be performed, while the emotional disturbances to which it gave origin presented problems to arouse the attention of physicians at every turn. In fact, no department of practice could be said to remain unaffected by the disturbing element of the menstrual functions, and thus it behoved each and every member of the profession to devote a special study to all in connection with the process.

The course of lectures to be delivered would deal with the subject under two heads, viz. :—(1) The Physiology of Menstruation, and (2) Its Derangements and Treatment, Therapeutic and Otherwise.

Inasmuch as all elementary knowledge could be recalled with advantage, particularly when of a scientific nature, and this because the consideration of such details by the

matured judgment ensured a truer appreciation of their meaning and relations, therefore it would be wise to preface the proper subject matter of the lectures by a brief outline description of the anatomical peculiarities of the parts concerned in menstruation.

Of these arrangements, the vascular and nervous offered points of especial interest, for the reason that the light shed on many obscure problems by an attentive study of the rôle played by these organs, alone enabled a clear understanding to be arrived at with regard to many intricate questions associated with menstruation.

The Ovaries, situated at the back of the broad ligament, $1\frac{1}{2}$ inches long, $\frac{1}{2}$ -inch wide, and $\frac{1}{2}$ -inch thick, lie in a position which enables them to be felt *per vaginam* only under certain favourable conditions, as a rule being distant from the roof of the vagina about an inch and a-half. Their blood supply is very free, and derived from three sources; (1) the *spermatic or ovarian* arteries arise from the forepart of the aorta below the renal varieties, coming downwards over ureter and external iliac, inclining inwards between the layer of the broad ligament, and thence to the attached border of the ovary. This vessel has anastomosing branches, with (2) the ovarian offset of the uterine artery, by which latter channel the ovary is also supplied with blood in considerable quantity. The third origin of supply is (3) the *Fallopian artery*, and it is easily seen that these united sources must convey a very considerable amount of blood to the parts they are distributed in. The venous system surrounding the ovaries is very remarkable for the number and extent of plexuses and networks presented by it, and a due comprehension of the facts it presents will largely assist appreciation of symptoms as they arise; and many of the points dwelt on in these lectures, being new to gynaecology, have as yet not been incorporated in any text-book of the science.

The object obtained by the free arterial anastomosis existing between the arteries that go to the organs under discussion, is more perfect discharge of the ovarian functions than would be possible without some such provision. It is certainly not for the benefit, primarily, of the surrounding structures, although they necessarily participate in the advantages thus conferred; and, notwithstanding the un

impregnated organ derives little good from the copious blood supply to it, yet the tremendous importance of such abundant flow, following impregnation, is readily perceived. By the existence, ready to be called into play at any time, of an arrangement of vessels whereby vastly increased volumes of blood can be hurried to the ovary without excessive enlargement of a single artery, as the proper uterine, there is removed an obvious inducement to serious disease. This would tend to demonstrate that it is the necessities of the ovary that are the principal elements determining this free supply of blood, and that the uterus and Fallopian tubes do not act materially as factors of arrangement in the matter. It should be particularly noted that inter-communication often exists between the various plexuses proper to the ovaries, and to the uterus, and that besides acting as channels for return of blood, they serve also to secure erection of the ovary, &c., whereby the Fallopian tube is brought into relation with the ovary, and the space between the latter and the uterus is bridged over.

The *nervous supply* of the ovaries is derived from the spermatic (ovarian) plexus, branches from the renal and superior aortic plexuses uniting to its formation. These plexuses being both situated high up in the abdomen, it is apparent that the ovaries are in nervous connection with the abdominal viscera, and also through inter-communication of the superior aortic plexus, the several nerves and sympathetic ganglia, they are extensively related to the brain, spinal cord, and other organs. These facts are of the utmost importance, as assisting to explain the wide-spreading disturbances possible to arise from any morbid condition within the ovaries; and particularly do they elucidate in some degree those subtle derangements incident to the "change of life." Even in the male-being phenomena in striking resemblance of character may be observed when changes are produced either naturally or artificially (as by castration), and which are exemplified in altered voice, or in those more general features associated with the advent of puberty, &c. In women, too, the observations of Dr. Meadows have shown, that marked changes may take place in the voice at the period of ovulation.

The fundus and upper part of the body of the uterus are chiefly concerned in menstruation, and a study of the anatomical structure and relations of these parts, and especially of their blood supply, must demonstrate the improbable nature of the mechanical system of uterine pathology, and the theory of strangulation of the uterus (Dr. Graily Hewitt) based upon it. This viscus is supplied with blood from three sources: (1) uterine arteries, directed downwards from the anterior division of the internal iliac to the neck of the uterus, and pursuing an exceedingly tortuous course on its walls; (2) uterine branch from the spermatic artery, thence being directed to the fundus uteri; and (3) a small branch of the epigastric.

The arrangements for the return of the blood from the uterus are especially worthy of attention, and in connection with them Dr. Meadows offers certain original observations tending to influence the theory of pathological disturbance of the organ. The bulk of blood from the fundus does not descend to the cervix, but finds its way to the bulb of the ovary, and thence into the spermatic vein. The upper and the lower parts of the uterus are, therefore, relieved of blood by entirely different channels, a point which cannot be over-estimated when considering the nature and cause of flexions of the uterus.

Through the nervous arrangement in connection with the ovaries it is possible to locate the position of injuries to these organs with a degree of exactness that affords opportunity for prompt measures of relief. Several plexuses supply the uterus with its nervous energy, and it must be borne in mind that its upper and lower portions derive their supply from different sources. The body receives filaments from the inferior aortic plexus, while branches from the spermatic plexus in the mid renal region go to the fundus, and pain felt along the back to the position of the kidney will sufficiently indicate the site of its excitation. Intimate relations, however, are maintained

among the different parts by aid of minute anastomosing branches, and the central point of the menstrual organs, the ovaries, are in direct nervous connection with the upper and mid portions of the uterus.

Ovulation, and the changes incident to the process, present many important and highly interesting subjects for study, much remaining in this direction for elucidation by future enquirers. Dr. Meadows' own observations, indeed, lead him to believe that, contrary to the usual supposition, the ovaries are engaged in active functional performances both before and subsequent to the menstrual life of the individual. In proof of this may be cited those occurrences of pregnancy that have been recorded on good authority as taking place earlier than, and long after, the appearance of menstrual excitement; also that the ovaries are the seat of grave disease after the menstrual activity has terminated, so far that it is as external evidence is concerned.

The importance of vascular, and particularly of nervous, arrangements as determining the physiological products of ovulation, cannot be over-estimated, and so intimately is the connection between the factors one of cause and effect, that the consideration of physiological and anatomical details might be accepted as a means of inferring those changes which must be the necessary outcome of the process of ovulation. Furthermore, it becomes a difficult matter in this connection, to sharply delimitate the point at which we are called upon to deal with physiological as distinct from pathological processes, so closely do natural and normal impinge on diseased and irregular conditions. Cases illustrative of this truth might be quoted in number, and as bearing on it the following possess interest:—

Twenty years ago Dr. Meadows had under his care a single woman, *æt.* 23, who since her childhood had been troubled with a swelling in the right inguinal region, which underwent no apparent increase in size, and was thought to be a rupture. At fifteen years she menstruated, often with accompanying pain. Three years ago a second swelling made its appearance under the first tumour, and smaller in size. Menstruation now became exceedingly painful, and was attended with increase of the tumour, and eventually it grew so acute that the patient was confined to bed during the periods of her flow. She had been examined by a hospital surgeon three months before coming under Dr. Meadows on July 21, 1861; hernia was diagnosed, but operative interference declined by the surgeon. Dr. Meadows believed the lower tumour to be ovarian, but agreed that the first was hernial in character, and recommended the adoption of surgical measures, an opinion concurred in by, among others, Sir W. Fergusson. On August 27 chloroform was administered to the patient, and Mr. Lawson removed the lower tumour. No adhesion was encountered; the cyst was punctured, separated, and pedicle ligatured. The growth was found to be the right ovary much altered in nature, containing many spaces filled with serous fluid, and exhibiting no proper graafian follicles; it weighed three and a-half drachms. The patient did well, a slight abscess alone giving any anxiety for a time, and though the first subsequent menstruation was somewhat painful no uneasiness was experienced afterwards. The point of special interest in this case is that the size of the tumour underwent periodical increase coincidentally with the periods of menstrual excitement, and its bearing on the propositions previously enumerated will be apparent.

A second example in illustration of the same principles occurred in the practice of Mr. Christopher Heath, *E. V.*, *æt.* 19, single, was operated on for left ovarian disease, and at the time, the right ovary was seen to be much enlarged, while one particular point of the organ presented a shining glistening appearance, surrounded by a zone of injected vessels, and limited by a further and paler zone, the whole organ being in a state of hyperæmia. The operation was performed at 10 a.m., on the 4th of November. On the 6th menstruation set in and lasted three days, so that it may be accepted that the signs ex-

hibited by the right ovary in this patient were those indicative of oncoming rupture of a graafian vesicle; and those, therefore, preceding normal menstruation. The history here given proves that the ovary undergoes considerable enlargement at the "period," and that this is, normally, unassociated with manifestations of pain.

Menstruation is synonymous with changes in the uterine organs, which in their totality are significant of the event; but also the ovaries and uterus react, during these changes, in a definite and constant manner, through the agency of vascular and nervous channels of communication and connection. The ovary being the actual centre, however, of the functional activity which inaugurates these changes, it is improper to give the place of importance to the uterus, as is done when "the uterus and its appendages" are spoken of; rather should it be rendered "the ovary and its appendages," by which phrase the position proper to itself is accorded to the ovary, the chief essential organ of the series.

The question of reflex impressions is one which is deeply interesting in connection with the subject in hand, and one, too, on which opinions are not generally expressed in a way that truth demands. It has been already explained how the nervous system serves to bring the ovaries into relation with the other viscera, and how disturbance in the former may suffice to set up unusual conditions in the latter. For instance, excessive excretion of urine is a commonly observed occurrence in certain forms of hysteria, and it is possible to understand how ovarian excitement may induce renal activity through the connection whereby the spermatic plexus of nerves, whence the ovarian supply is derived, is associated with the renal plexus. But it is unjustifiable license of language to denominate this a *reflex* action, since it possesses none of the proper characteristics of reflexes, but is purely and solely *direct* in nature. Recent inquiries have clearly demonstrated how the sudden excitation of function in an organ may react on its blood supply, causing dilatation of afferent vessels, and almost unlimited augmentation of secretion.

It has been shown that the fundus and upper part of the uterus, is that portion of the organ chiefly in nervous connection with the ovaries, and with this it is significant to know that the menstrual flux is not from the cervix, but from the fundus and body, a fact proved by Mr. Arthur Power, who observed in a woman dying during a menstrual period, that these parts of the uterus were those in active vascular turbulence. Such a discovery is but another argument in favour of the dependence to be placed on anatomy and physiology alone as aids to comprehending pathological changes and their consequences.

A NEW AND RELIABLE OPERATION FOR THE CURE OF WEBBED FINGERS.

By ARTHUR T. NORTON, F.R.C.S.,
Surgeon and Lecturer on Surgery at St. Mary's Hospital.

C. K., was sent to me by Mr. Moore, of Chiswick. The boy, one of four children, was about four years of age, and had the three inner fingers of the left hand webbed together. No relative had suffered from the same deformity. The operation which I performed can be best explained, and, indeed, can only be understood, by referring to the diagram.

A tongue of integument was cut from between the knuckles, and another, corresponding in shape, and position, and size, on the palmar surface. These tongues were then raised by dissection, and the webs cut through. The knife was then carried back so as to sever all the tissues as far back as the bases of the tongues, and a little super-abundant tissue was removed. Next, the apices of the tongues were sewn together, and lint dipped in cold water applied. The flaps or tongues united by

the first intention between the little and ring fingers, but one of the pair between the ring and middle fingers sloughed at its apex from its suture. The cause of the sloughing was incomplete section of the tissue between the fingers up to the base of the tongues, the result of which was too great tension, and consequently giving way at the suture. However, even in this case, the tongues separated only a very short distance, and the interspace rapidly healed, so that there was no re-development of the web.

A drawing of the hand was taken after the operation, by which it will be seen that in the case of the middle and third finger, a little more tissue might have been removed with advantage after the raising of the tongues, in order to bring the lines of the natural web in proper position. The healing of the fingers progressed rapidly in the middle finger and on the outer side of the ring finger. Between the ring and little fingers the healing was not so rapid, because the web between these fingers was thick and narrow, so that, after its section, a larger surface was denuded.

The points to be considered in performing the operation are: 1. The tongues should be cut thick, so that their vascular supply may be complete, and the chance of their sloughing reduced to a minimum. 2. They should be cut rather narrow, with judgment; otherwise, they get compressed laterally and bulge upwards at the margins, instead of lying in adaptation to adjacent tissues. Such compression, of course, interferes with their circulation. 3. The tissue between the knuckles is to be cut back, or, if necessary, cut away, so that the apices of the tongues shall lie well in contact with each other without tension. 4. The tongues must be of sufficient length, so that there shall be no tension when the suture is applied; they had better be too long than too short. 5. The apices of the tongues are very small, so that a very small needle should be used to carry the suture. 6. In shaping the tongues the line of the natural web should be carefully observed. If the tongues heal by first intention, no web can re-develop. There is no reason whatever why union by the first intention should not invariably take place if the above points are remembered whilst performing the operation, and thus one of the most troublesome and unsuccessful of operations is converted into one of the most simple and most certain of success.

CLINICAL LECTURES ON SYMPTOMS.

Delivered in the Wards of the Hospital.

By FREDERICK T. ROBERTS, M.D., B.Sc., F.R.C.P.,
Professor of Materia Medica and Therapeutics at University
College; Physician and Professor of Clinical Medicine at
University College Hospital, &c.

LECTURE I.—(Continued.)

1. *Superficial Observation.*—You must be prepared, whenever a patient comes before you, to take note of any symptoms which may be at once evident to the most superficial observation, and which immediately strike you and attract your attention. Not only should you be on the alert to take in what you see, but also what you hear, smell, or feel. To give a few examples of symptoms thus immediately recognised, you may see jaundice, dropsy, cyanosis, anæmia, emaciation, dyspnoea, hæmorrhage, unconsciousness, convulsions, or choreic movements; you may hear peculiar characters of breathing or cough, the stertor of apoplexy, the moaning suggestive of suffering, the wandering of delirium, or rumbling sounds in the abdomen; you may smell the peculiar odour of the body associated with certain febrile diseases, such as rheumatic or typhus fever, or that of the breath indicative of ulceration or gangrene, or of alcoholism; you may feel burning heat, profuse sweating, or marked dryness and harshness of the skin. It is remarkable how often, after due experience has been gained, this superficial examination will reveal, or at any rate afford a good clue to the nature of the complaint from which the patient is suffering, and will give a direction to further inquiry. Of course, the phenomena thus ascertained must only be taken for what they are worth, and we must always guard against placing too much reliance upon them.

2. *Questioning.*—The next mode of investigation is to find out what the patient, his friends, or others who are in a position to give the required information, can tell you about the symptoms. If intelligently and properly conducted, this method is in most cases very satisfactory, and affords valuable aid in diagnosis. It is well, in the first instance, as a rule to hear what symptoms are complained of; and then the practitioner can ask such questions as may thus be suggested, or which it may be necessary in his judgment to inquire into. Now this questioning ought to be proceeded with in an intelligent and orderly manner, and with a clear comprehension of what you want to ascertain. It is absurd and amusing sometimes to hear the questions which patients are asked, evidently having no meaning whatever, or any bearing on the case under examination. The course and minuteness of your inquiry must be guided by circumstances, and let me remind you that it will require no small amount of practice on your part before you become able to conduct it satisfactorily in a good many cases. It implies a knowledge of details relating to symptoms which many do not possess, or take the trouble to acquire; and also a habit of investigating as to these details, which is frequently not practised. From what I have previously said, it will be evident that concerning *subjective* symptoms we chiefly gain information in this way, and what I have stated when speaking about these symptoms will put you on your guard against taking a patient's statements without due consideration on your part; moreover, you must be particularly careful not to accept patients' *explanations* of their sensations, which many are very fond of giving, attributing them to particular organs or diseases. It must not be forgotten, however, that we may learn by questioning many facts about *objective* symptoms, such as cough, dyspnoea, vomiting, palpitation, &c., which we ought to know, but which we have no opportunities of observing for ourselves. On these matters we may gather much information often from intelligent relatives, nurses, and others, as well as from patients themselves.

3. *Objective Examination.*—One of the most important parts of the clinical examination of a patient, in a large

number of cases, is for the practitioner personally to observe any ordinary *objective* symptoms which may be complained of or revealed on superficial investigation, or to look for such symptoms if he has any reason to suspect their existence. I have already said that a patient's statement should never be accepted as to the presence of objective symptoms, although he may be able to give you details concerning them; and I now emphatically repeat this remark. For instance, if a patient complained to you of a swollen leg, and you believed him without seeing for yourselves, you would be falling far short of your duty. These objective phenomena are usually very suggestive and instructive. They often reveal all you want to know, and do away with the necessity of much or any questioning of the patient. Indeed, if there are evident objective symptoms in any case, it may be stated that, as a general rule, these should be attended to at once, and thus a good deal of time will probably be saved. You are by them attracted frequently to a particular organ, or, it may be, even to a particular disease, and your diagnosis is quickly made, provided, of course, that you know the symptoms which belong to each organ or structure, and which are associated with the several diseases that you are likely to meet with. You will bear in mind that what we regard as objective clinical phenomena are not only those we see, but also include those we recognise by the aid of the other external senses. It is therefore frequently necessary to make the patient do some act which brings out a sound we want to study, such as to cough; or we use our hands and fingers to examine external swelling and other objective signs; we apply the sense of smell to certain special objects, and so on. These points will be made more clear when we come to study the various local and general symptoms. In the meantime, I hope what I have said will have impressed upon you the essential importance of investigating for yourselves all kinds of objective symptoms, in so far as you are able to do so. Remember also that objective examination may help you in the study of subjective sensations.

4. *Ordinary Physical, Chemical, and Microscopic Examination.*—Intimately associated with the mode of investigation just considered, inseparable from it by any marked line of demarcation, and yet demanding special recognition, is that which may be termed *ordinary physical examination*, with which may be associated the simpler methods of *chemical* and *microscopic* examination. So important do we consider this subject, that, as you are aware, it is systematically taught at this hospital in all its branches by the Assistant Professors of Clinical Medicine; and I devote one of my demonstrations every week to its practical study in cases illustrating the different physical signs, and the physical conditions upon which they depend. Therefore, I need not enlarge upon it at present, and only desire to draw attention to two or three points. I include under this general heading such methods of physical and other forms of examination as you ought all to be familiar with, and should be prepared to carry out in any case which comes under your care; and the following list will indicate what these methods are, so far as medical practice is concerned:—

- (a) The use of the clinical thermometer.
- (b) Examination of any obvious external morbid condition, such as a swelling or tumour.
- (c) Examination of the mouth, throat, and tongue.
- (d) Ordinary physical examination of the chest, and of its contained organs and structures.
- (e) Ordinary physical examination of the abdomen, and of its contained organs and structures.
- (f) Examination of the urine, so far as to determine its common morbid conditions.
- (g) Examination of the blood-vessels generally, including the pulse.
- (h) Chemical and microscopic examination, so far as to be able to apply these modes to the more simple investigation of the blood, vomited matter, stools, expectoration, discharges of various kinds, morbid products, particles from the skin, &c.

(i) Examination of the nervous system up to a certain point.

(j) The employment of simple operative procedures for diagnostic purposes, such as removal of fluid by the aspirator.

Now these methods of clinical examination are within the reach of every one of you, and you ought not only to learn them, but also to carry either of them out in practice, whenever occasion seems to indicate that it can be of service in diagnosis.

5. *Special Skilled Examination.*—There are certain methods of clinical investigation which may be called for in particular instances, and which are of a more elaborate character than those just considered. You may, if you choose to do so, and ought to qualify yourselves now for carrying out most of these methods, by the aid of your surgical teaching, special classes, and attendance in the various special departments. Probably, however, many of you will not do this, and it must be recognised that not a few are unable to acquire the skill necessary for practising some of them properly while even if you do learn them, cases in ordinary practice requiring their application will probably occur so rarely, that you may lose any skill you have once gained. Therefore, it may be necessary for you to call in the aid of one who is specially skilled in a particular mode of examination; and you should not hesitate to do so if you think it desirable, and you are not competent to carry it out. I would include the following under this group:—

(a) The use of special instruments, such as the laryngoscope, ophthalmoscope, sphygmograph, cardiograph, hæmacytometer, &c.

(b) The skilled examination of particular internal organs, as the œsophagus, stomach, bladder, or female generative organs.

(c) Elaborate chemical or microscopic investigation, applied to the blood, urine, vomited matter, discharges, &c.

(d) Skilled examination directed to the nervous system. This is often very complicated, various instruments being required, with electricity and other methods, which demand much education and practice.

(e) Examination of the special senses.

(f) The more serious operative procedures for diagnostic purposes, such as abdominal section.

This outline will serve to convey to you a general idea of the course you may be called upon to pursue in the investigation of a particular case.

(To be continued.)

Clinical Records.

MEATH HOSPITAL, DUBLIN.

Case of Epithelioma of Tongue.

With observations thereon by Mr. HEPBURN, Surgeon to the Hospital.

Reported by Mr. W. H. B. ROBINSON.

JOHN CODY, æt. 55, married, a labourer, was admitted into the Meath Hospital, under Mr. Hepburn, on Tuesday Sept. 27th, 1881, suffering from Epithelioma of Tongue. *History*—In June last he noticed a small sore on right side of tongue, near the point, which he thought was caused by a loose tooth, which he had had extracted, without relief. He attended a dispensary for some time, receiving treatment, but without effect. The first symptom he noticed was soreness of tongue and mouth when smoking, this was soon followed by increased flow of saliva, and later on by difficulty of swallowing, which, however, shortly afterwards subsided. He states he never had syphilis, nor is there any appearance of the disease on minute examination.

Appearance on being admitted.—Tongue sharp pointed, right side partially ulcerated, edges being ragged, with mushroom-like margins, which encroached upon the floor

of the ulcer, there was much deep hardness on the affected side, which however, terminated in a well-defined margin of about one inch, beyond which all seemed healthy. No enlargement of the sub-maxillary gland nor infiltration of the floor of the mouth could be detected. He was suffering also from profuse salivation, and neuralgic pains darting up into right ear, especially at night.

Oct. 5th.—The patient being placed in the semi-recumbent position, and ether having been administered, the mouth was opened and firmly fixed so. The tongue being pierced with a curved Lister's needle carrying a double ligature of strong thread such as sail-makers use, it was raised to the roof of the mouth. Instead of cutting the sub-lingual attachments with the knife, it was suggested by Mr. Macnamara (my colleague) that I should do so with the chain écraseur (thus performing Mr. Holt's modification of Sir J. Paget's operation). In order to do this, it was only necessary to introduce a curved needle under the tongue as far back as possible, and to attach the chain to the loop of the ligature with which the needle was armed, so as to include as much as possible of the sub-lingual structures with the chain which was pulled through. The chain was slowly tightened and worked home. The tongue now being loosened and capable of being drawn forward, a strong curved needle was passed through the tongue (well behind the diseased mass) bearing a double ligature. The ligature was separated, and two écraseur chains were successfully pulled through the single opening in the tongue; these were screwed up and worked out, thus removing the greater part of the right side of the tongue. The wound was then brushed with a 40-gr. solution of chloride of zinc, and the mouth washed out with iced water. A piece of ice was then put in the patient's mouth and he was placed in bed, where he shortly afterwards fell into a calm sleep.

6th.—Slept well, takes nourishment freely, no hæmorrhage.

7th.—Complained of some difficulty in swallowing, tongue considerably swollen, ordered a linseed-meal poultice, and a mouth wash containing a dilute solution of perinanganate of potash.

8th.—Better able to swallow, in very good spirits and inclined to talk, wound granulating healthily.

10th.—Swelling greatly decreased. Ordered a gargle containing chloride of potash with tinct. thymol.

13th.—Allowed to get up.

15th.—Wound healing rapidly, and looking quite healthy. Neuralgic symptoms completely gone, no salivary trouble. Partaking freely of nourishment.

28th.—Wound almost healed. Became an out-patient.

Remarks.—Removal of the entire portion of the tongue will be regained almost exclusively for the epithelioma form of cancer, true schirrus or encephaloid being extremely rare, some even stating that of their existence there is no certainty. As a clinical fact, which supports this view, the cases of what is commonly called cancer of the tongue invariably commence on the surface, and nowhere do we find instances of cancerous infiltration in connection with and unpreceded by ulceration. Nor do, so far as I know, museum or post-mortem specimens reveal the presence of other forms of cancer as primary affections of this organ. Errors of diagnosis no doubt have caused syphilitic hardening to be mistaken for cancer, but even in these a sore on the surface is mostly, if not always found. Epithelioma of the tongue seems to advance either in two ways, or rapidly. The case reported would seem to belong to the latter class, for the disease seems to have progressed to a serious extent in less than four months.

It is in the former, i.e., the slowly advancing tumours, that early diagnosis is so difficult. The number of what I shall call "suspicious cases" is painfully familiar to the operating surgeon, who finds a slight crack or fissure of the tongue caused perhaps by contact with a decayed molar tooth. Is a patient of confessed

specific taint and general localised hypertrophy of the papillary structure of the tongue itself.

Icthiosis.—These affections exist for a longer or shorter period, and though they appear to yield to local or constitutional treatment, yet may terminate in unmistakable and rapidly spreading cancerous disease. In the future development of surgical research we may yet be enabled with certainty to point out when this change commences, and perchance to anticipate the period of malignant cell development. But as yet I fear we must rest satisfied with the relief to be afforded by an early operation, in apparent cases, ere glandular complications appear which too certainly proclaim that epithelioma of the tongue is no longer truly and solely a local affection. When the diagnosis has been established the early and free removal of the tumour affords the only prospect of relief. Having discussed the various operations proposed for removal of segments of the tongue, Mr. Hepburn continued, as to the results of the operation, my personal experience is not worth naming, but I think I am correct in stating that the few recorded cases in which the disease has not returned after a longer or shorter interval, if viewed only as results, would not give much encouragement for a repetition of the operation. But, I do not think we would be justified in measuring the benefits of the operation solely by the cases which remain free from permanent relapse. These are as yet but few for no very long time has elapsed since the operation was considered even justifiable much less simple comparatively painless and safe. I would rather direct attention to the immediate advantages arising from exemption from great distress—freedom from severe pain—greater ability to breathe and swallow—starvation averted and comfort secured—arrest of salivary and purulent discharges so wearing to the patient, even for a limited period, benefits not to be lightly regarded, when they can be secured by a safe surgical operation. I shall say nothing of the advantages or disadvantages of the other operations I have referred to when compared with the one selected for this case, namely the simple *écreuseur* of Charinière, but I shall conclude by observing that in my mind the result has been sufficient to justify its repetition in a similar case.

SURGICAL SOCIETY OF IRELAND.

THE First Meeting of the Society for the Session 1881-2 was held in the Albert Hall on Friday evening, the 25th ult.

SAMUEL CHAPLIN, Esq., M.D., President of the College, in the Chair.

MR. JOLIFFE TUNNELL, one of the Hon. Secs., read the minutes of the last meeting.

The PRESIDENT read the following address:—

GENTLEMEN,—In an Association like this, assembling after an interval of some months, each member looks forward with feelings of pleasure to meet again his brethren, and initiate those meetings for the encouragement of that particular branch of science for which each of them was formed. So it is with us in this, the Surgical Society of Ireland; grateful to meet so many of our friends here to night, we are happy to find that we miss so few from among the familiar faces usually assembled on an occasion like this, yet we are painfully reminded that those we miss we shall never see again. Death has laid his hand upon Alfred Henry McClintock, late President R.C.S.I., and of this Society, on Thomas Hayden, Vice-President K.M.Q.C.P.I., and on Alexander Carte, all members of this Association. I feel it difficult to speak of their merits in the presence of those who have been more intimately acquainted with them than I have been, who have met them in their professional capacity, and have known and valued their private worth; but I feel I would be wanting in paying that respect to their memory if I did not take this

opportunity of recording that, which I am sure, is the feeling which pervades this Association, that of deep and sincere regret at the loss which, not only this Association, but the profession and public have met in their death. The late Dr. McClintock was born in Dundalk, commenced his career as apprentice to Dr. Brunker, a gentleman well-known for his ability and skill as the then surgeon of the County Infirmary there. From the Dundalk Infirmary, where he had opportunities of acquiring a large amount of both surgical and medical information, he came to Dublin, and having studied in the Park Street School of Medicine, he became a Licentiate, and subsequently a Fellow, of this College. He also graduated in medicine in Glasgow University, and finally decided on settling in this city. You are all aware of his career since then. Having been appointed assistant in 1843 to the Rotunda Hospital, and subsequently its master, he utilised to the utmost the great opportunities which that noble Institution afforded for studying midwifery and gynaecology. His term of mastership having terminated, he soon took a foremost position in that branch of the profession which he had selected, and which he maintained till his death. His earlier writings in connection with the late Dr. Hardy are familiar and valued. His memoirs on diseases of women will remain among the standard works of this branch of surgery. The professional public have acknowledged his great merits in the lucid diction, the accuracy of description and logical deduction with which his writings abound, and the University of Edinburgh thoroughly appreciated his great talent and acumen in his comments and annotations on Smellie's "Midwifery," as published by the Sydenham Society, conferred upon him *honoris causa*, the degree of LL.D. Although failing strength had overtaken him, and his bodily health was on the wane, the powers of his gifted intellect shone forth none the less, and at the great Medical Congress, held last summer in London, he, as President of the Obstetrical Section of Surgery, delivered the Introductory Address long to be remembered by those who had the opportunity of hearing it. I cannot pass over the period when the late Dr. McClintock governed us in this College as its President. You, of its Council, who have felt his kindly rule, must have admired the genial manner with which he discharged the onerous duties of his office; and the tact which he displayed in settling many points of difficulty requiring knowledge, toleration, and mature judgment. He was one who could bear and forbear, yet would not deviate in the slightest degree from the course which he considered right. In his private life, he was beloved by those who had the pleasure of his intimate acquaintance, for his kind and gentle disposition, his upright and honourable bearing, and his thorough honesty of purpose. For years he devoted himself to the advancement of the Royal Medical Benevolent Society, and none that have heard him, as its honorary Secretary, read his reports showing its work, and its wants, but have felt the great influence of his appeals for this charity. He administered to the poor on the principles which actuated his whole life—as part of his duty—and as it was truly said at his grave "His left hand knew not what his right hand did."

The late Dr. Hayden was born in the county Tipperary, and at an early age came to Dublin, where he received his medical education and was finally induced to settle. He became a Licentiate and subsequently a Fellow of this college; but resigned the latter position on being elected a Fellow of the K. & Q.C.P., of which he was also a Licentiate. Soon after having received his earlier diplomas, he became connected with the Ledwich School of Medicine, was shortly afterwards appointed Physician to the Mater Misericordie Hospital; a position which he held to his death, with advantage to it, and honour to himself; and when a Catholic University was founded, he was selected for the Chair of Anatomy and Physiology in it. As physician to the above mentioned hospital, he took the greatest advantage of the opportunity which it afforded of studying disease, and stored up the valued information which he communicated some time since to the public in his work on diseases of the Heart, and Aorta. Observant, careful in discovery, and noting down his experience, he described with great truth and accuracy, the changes in the heart, which disease produced and localised the effects of those changes on this important organ. His researches in this direction as well as his earlier contributions in medicine, physiology, &c., were much valued, and had created for him a reputation which was

largely bearing fruit. He caught cold in the discharge of a public duty, got inflammation of the lungs, and having struggled against it for many days succumbed to it. Among his professional brethren, he was highly respected for the soundness of his opinion, and his advice was much sought for. As a teacher Dr. Hayden was greatly esteemed by the students, for his assiduity and the manner with which he communicated information to them. They will regret his death not only as the teacher, from whom they received knowledge, but as the kind friend, who sympathised with them in their difficulties, and rejoiced with them in their success. He was much beloved by his friends, both in public and private life, and it might be truly said of him, he had hosts of friends and never made an enemy.

Dr. Carte has also passed away from amongst us. Who, that have been students of this college when he occupied the responsible position of Curator of its Museum, will forget his urbanity and the kind readiness with which he assisted them in their studies in it. He became curator of the museum of this college, and continued to discharge his duties with the greatest ability till he was elected Curator of the Museum of the Royal Dublin Society; since then, he had, until recently, performed the duties entrusted to him there with skill and ability, and only retired when failing strength warned him that he must no longer hold the trust committed to his charge. He died honoured and sincerely regretted by all who had the pleasure of his acquaintance. As a curator, his works testify to his ability, both here, and in the Royal Dublin Society. None more genial in his disposition, kindly in his nature, or more to be loved than Alexander Carte, has passed from amongst us.

In those we have lost were men who, each in his way, was an ornament to our profession. Their mark has been left on the Medical and Surgical records of their times, and their names will adorn the long beadroll of the distinguished members of this Association. They are gone, their faces will be no more seen in these halls, but their memory will remain long cherished by those they have left behind.

(To be continued.)

Special.

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

URINARY FISTULA.—At the last meeting of the Academie de Medicine, M. le Dentu communicated an interesting case of urinary fistula of the left inguinal region, consecutive to a peri-nephritic abscess that occurred in his practice, and for which he extirpated the corresponding kidney with success. He was called to an individual, *æt.* 32, who was affected with a fluctuating tumour of the left iliac fossa, and suffering great pain. In the most dependent part, M. le Dentu made an incision, and a liquid, clear, but soon mixed with blood, flowed from the wound. In a few days the urine commenced to issue in abundance through the same aperture. However, after a short time, the liquid diminished considerably, yet never totally, and gave rise frequently to inflammatory attacks, followed by suppuration. The life of the patient being compromised, M. le Dentu proposed extirpation of the kidney which was agreed on. The decortication was easy, and the renal organ was found to be degenerated in its two upper thirds, and converted into a cyst, which was voluminous. Two ligatures of cat-gut were thrown round its base, and with the scissors ablation of the tumour was effected. All antiseptic precautions were used. During some days the patient was very low, the pulse varying between 120 and 145. The temperature was about normal. The operation wound was completely cicatrised at the end of two months. As to the fistula, that was enlarged by the thermo-cautery on the day of the operation, it is not yet completely closed, it gives issue to a few drops of purulent serosity daily, but no urine, the flow of which, by the ordinary channel, had never been disturbed, and the patient, who is a distinguished dramatic artist, has been able to make a brilliant appearance last month.

SPONTANEOUS CURE OF VAGINAL HERNIA.—An extraordinary case of spontaneous cure of vaginal hernia, followed by perforation, has occurred in the service of M. Auger, of the St. Antoine hospital. A woman, *æt.* 25, mother of two children, who became for the third time *enceinte*, and displeased at this new pregnancy, consulted a midwife as to the best means of procuring abortion. Injection of tepid solution of coarse salt was advised and practised. The syringe employed had a long canula, and its intro-

duction into the vagina caused considerable pain. Three injections were used, an interval of a week being allowed between each, and soon hæmorrhage, very abundant, was excited. On the day of her entry into the hospital, the patient on sneezing, felt a tumour in the vagina, and soon it appeared at the orifice. Frightened, she came to the hospital, when, on examination, a tumour of a dark violet colour, and resembling a loop of intestine, was observed between the labii. It was soft and seemed to contain gas. On exploring with the finger in the vagina, the hernia was partially reduced, but it was impossible to find the point through which the intestine passed, neither could the os uteri be reached. However, no loss of substance could be detected in the recto-vaginal wall. There was no nausea or vomiting, the pulse was not accelerated, nor was the temperature lowered, the abdomen was not tympanitic. Rest and constant poulticing was ordered. The following day the tumour was observed to be of a darker hue, which, towards evening became still blacker and more salient. It also smelt gangrenous. The general health remained always undisturbed. On the afternoon of the third day the bowel burst, giving exit to hardened fecal matter mixed with a blackish and foetid liquid, and a great quantity of gas. For two days fecal matter continued to pass through the artificial anus in abundance, but on the fourth day it had completely ceased, the bowels evacuating themselves through the rectum regularly. On passing the finger into the vagina no trace of the recent perforation could be found. Examination by the speculum gave no better results. On the twentieth day of her residence in the hospital, the patient returned home in her usual health.

NERVE STRETCHING.—M. Palailon communicated to the Société de Chirurgie a case of nerve stretching that was practised by him for severe neuralgia of the fifth pair on the right side. A man, *æt.* 61, entered his service in the hospital La Pitié suffering excessively from rebellious neuralgia, which was particularly manifested in the parts animated by the sub-orbital, lingual, and above all the inferior dental nerves. Bromide of potassium, chloral, morphine, &c., were given without benefit. Stretching of the superior dental nerve was decided upon, and for that purpose an incision was made in the form of an L, over the right ascending ramus of the inferior maxillary bone. A trepan was applied, and the nerve, which presented itself under the form of a white cord, and by no means congested, was reached. By means of a small hook it was drawn out of its bed gently for about half an inch, and then replaced. This operation was followed by considerable relief, but soon the attacks commenced as bad as ever. However, the medicines that hitherto proved unavailing, had now the best effects, and to-day, two months after the operation, the cure is complete.

TEPID WATER IN CHRONIC CYSTITIS.—In chronic cystitis accompanied by a little fever ammoniacal urine, and charged with mucus, with frequent desire to micturate, M. Thonton, after emptying the bladder, recommends the injection of at first four ounces of tepid water which is allowed to run out immediately afterwards; then an injection of the third part of the following solution:—Quinine 16 grains, sulphuric acid, q. s., distilled water ten ounces. The liquid thus injected is maintained some seconds in the bladder, after which two-thirds are allowed to flow out, while the remainder is left for an hour in the urinary reservoir. This injection produces a very slight smarting, and after a treatment of some days, the urine becomes acid and no longer contains mucus.

THE COCOA-NUT AS A REMEDY FOR TAPEWORM.—In the Antilles the cocoa-nut is the popular remedy for tapeworm, and its efficacy has been conclusively demonstrated by medical men in Senegal. A cocoa-nut is opened, and the almond extracted and scraped. Three hours after its administration, a dose of castor oil is given. The worm is expelled in two hours afterwards. In nine cases in which this remedy was tried by a surgeon in Senegal, the result was complete.

FROM DISEASES OF THE ZYMOTIC CLASS last week in the large towns, the death-rates per 1,000 were from scarlet fever 10.8 in Hull, 3.3 in Nottingham, and 2.4 in Brighton; from measles, 3.5 in Liverpool, and 2.0 in Manchester; and from "fever" 1.3 in Bristol, and 1.0 both in Hull and Brighton. In Hull 32 more fatal cases of scarlet fever were recorded, making 502 since the beginning of July. The 49 deaths from diphtheria included 26 in London, 12 in Glasgow, and 5 in Portsmouth. Three more fatal cases of measles were recorded in the Manchester Workhouse at Crumpsall. Small-pox caused 23 deaths in London and its outer ring of suburban districts, one in Brighton, and one in Newcastle-on-Tyne; no fatal case of this disease was registered in any of the other large towns.

Hospital, Physician to the Hospital for Diseases of the
Throat, &c.

(Continued from page 169.)

THERAPEUTICS OF TABLE WATERS.

In studying this part of the subject it is essential to bear in mind what has already been stated with regard to the consumption of ordinary potable water in varying quantities, and at various periods of the day. All that we have there said necessarily applies to the use of such mineral waters as are recommended to be taken at table. Some of these are feebly saline, others are slightly alkaline, a third class—containing iron—are called chalybeate or tonic, while some less common constituents give a character to others. In waters intended for constant use it is obvious that the mineralisation must be moderate, and in some cases the ingredients are such that very small quantities suffice to render the water a medicinal rather than a dietetic agent. Thus table waters with a considerable quantity of salt approach in character saline waters. Those containing sodium carbonate are related to the alkaline waters, and those with small quantities of iron have a claim to be admitted into the class of chalybeates unless the proportion of metal is very small. Most of these waters contain free carbonic acid, an agreeable stomachic frequently employed in other forms, to which some of the qualities of the beverage are unquestionably due. The familiar effervescing draughts and the artificial aerated waters of commerce have their uses. Richter has recommended artificially aerated distilled water as a menstruum, and lately it has been offered us as a beverage, as if it were a novelty.

It is an error to suppose that the value of a water is in proportion to the amount of gas it contains. A large quantity is expelled from the stomach almost as soon as swallowed, or else is liable to cause distress. Hence waters containing a moderate amount are found more digestible. When, however, a suitable water is found to contain more gas than agrees with the stomach, the dose can be allowed to stand awhile so as to let the carbonic acid escape. From 5 to 10 or 12 cubic inches per pint of water is an agreeable quantity, and within these limits the beneficial action on the stomach and bowels is most marked. It will be said that our ordinary aerated waters sometimes have a large quantity forced into them, but it should be remembered that much of this escapes the moment a bottle is opened, and many persons find it better to sip these than to drink them off. Moreover,

one of their most important uses is to mix with a non-aerated fluid like milk. In the gaseous saline waters the constituents are rapidly absorbed, and the digestive energy of the carbonic acid well marked. But instead of going over the general therapeutics of table waters we will pass in review those of which we have given analyses.

Seltzer.—This claims first place as the general favourite which has longest maintained its repute. Our new analysis will correct the impression which has generally prevailed as to its ingredients, and give an idea of its action. It is both antacid and saline. The slight alkaline reaction of the water depends on the fact that its antacid quality is, for the most part, due to alkaline earths, though, as will be seen, it does contain some sodium bicarbonate. The saline quality is largely due to the sodium chloride, which is added to the water when it is bottled. The purgatives, it will be seen, are only in minute quantity, Mr. Tichborne's careful analysis giving only one grain in the half-pint, and yet it is a common observation that the use of seltzer increases intestinal action. This confirms what we have stated as to the value of gaseous and other waters in constipation. All who require a gaseous, feebly alkaline and saline water, with a tendency to relax rather than constipate, may therefore try seltzer. Its saline constituents give it the refreshing quality which assists in allaying thirst, and the gas makes it palatable. It promotes the secretions of the skin and kidneys. It can be mixed with milk, but it is not so pleasant in this form as artificially aerated and alkaline waters. It is a pity it is not universally sold in glass instead of stone bottles.

Taunus.—Here we have a palatable calcareous table water, containing no purgatives, but as rich in salines and antacids as the seltzer. As the antacid quality is due to the carbonates of the alkaline earths, some persons may find it sit rather heavy on the stomach, and some may think it constipating. On the other hand, it might be preferred where earthy salts are supposed to be indicated.

Harzer.—This is a pure, light, antacid, saline, gaseous water, very pleasant to the taste, and grateful to the stomach. The alkaline reaction is due to sodium carbonate, and the saline quality to the same chloride. It contains even less purgatives than seltzer, so that it may be said to be non-aperient, but this minute quantity, with the other ingredients, suffices to render it non-constipating. It is an excellent digestive water.

Apollinaris.—This water has been so prominently brought before the public of late years that many people are under the impression that it was previously unknown. We, however, have long been acquainted with it, and some of our patients drank it regularly years before it was advertised in England. There are several springs, and we are not aware that the Company has purchased all. It will be seen that the Apollinaris water now in the market does not quite correspond with the original analyses. Prof. Tichborne finds it stronger, especially in sodium chloride, and carbonate. Of the former of these we are informed that a certain quantity is added. It would be interesting to learn whether any of the latter is also artificial, as otherwise the spring would appear to be increasing in strength, for we can scarcely suppose that so ordinary a salt would have been erroneously computed.

It may surprise some to hear that Apollinaris is closely related to seltzer, and yet a comparison of the analyses will show that this is the case. The two contain nearly the same quantity of solid ingredients, and they are distributed in a similar manner. Still there are some differences. Thus Apollinaris contains in half-a-pint more antacids and less salines than seltzer, and it has half as much again purgatives. It is, therefore, quite as digestive, rather more antacid, and more likely to increase the action of the bowels. It has a good supply of gas, and is tolerably palatable. Personally we should prefer it without the added salt. The Company boast so much of the "Chemistry of Nature" that they might perhaps make the effort to abide by her works without the additions of art.

WEDNESDAY, DECEMBER 7, 1881.

THE DIPHTHERITIC POISON.

PREVALENCE of diphtheria in several districts of England has recently renewed the interest some little time ago generally evinced in the nature of the *contagium* distinctive of the disease. That the attainment of any specific knowledge on this question would materially tend to perfection in treatment will not admit of doubt; and a keen sense of chagrin must be felt by all who consider how small are the chances of disco-

very in this direction being likely to be credited to English observers, so long as their endeavours are impeded by legislative prohibition of absolutely needful experiments. We have sufficiently good reason to anticipate that starting from the point already gained by the researches of Pasteur, Klebs, and others, and aided by the assistance to be obtained from the experiments referred to in these columns last year, as being carried out by Drs. H. C. Wood and Formad under direction of the American National Board of Health, we may speedily be in a position to oppose to epidemics of diphtheria measures of repression far in advance of those we are now compelled to employ.

By inoculating rabbits with shreds of diphtheritic membrane taken from the throats of human patients, Drs. Wood and Formad long ago succeeding in showing that in place of reproducing diphtheria—which occurred in a very few cases—tuberculosis was developed; and further that false membrane is developed in the trachea as a result of severe trachitis from whatever cause set up, whether from the introduction of diphtheritic membrane or otherwise. Now, however, a new fact of high importance is thoroughly established in connection with these membranes; they differ in appearance but little, if at all, from whatever cause produced, but in every case of true diphtheria they are loaded with micrococci, and also the blood and internal organs of the patients dying from the disease are similarly infected. Whatever suspicion may have been entertained, and undoubtedly it has been felt, that this explanation would sooner or later turn out to be the true one, it cannot be denied that much credit is due to the series of patient experiments whereby it has been established. The manner in which the micrococci accomplish their destructive labours has been shown to be through their attacking the white corpuscles in the first place. The leucocytes thus influenced lose their form and granulations and are ultimately invaded with micrococci to such an extent that they burst, giving exit to an irregular transparent mass, packed with micrococci, the so-called zoogloea mass. We may naturally assume the reproduction of the liberated organisms, and it is not difficult to perceive the consequences that may follow from their uninterrupted and virtually unimpeded development within the body. Contagiousness is preserved by the micrococci as was shown by communication of the disease from animal to animal artificially; and not least interesting among the facts brought to light is that showing that there is an identity of cause and effect connecting ordinary sore throat with the diphtheritic variety, micrococci being found in each, and differing only in the stage they had reached and the activity they exhibited.

The detailed reports of Drs. Wood and Formad are as yet unpublished, but they may soon be expected to appear. That they will be an important contribution to the literature of contagious diseases cannot be doubted for a moment, and taken in conjunction with other recent researches, and particularly those of Pasteur, it is difficult to see to what they may not give rise. The number of diseases in which the blood is primarily invaded by microscopic organisms, which latter are the exciting causes of pathological changes, is very considerable; and

the opinion gathers ground daily that the explanation of many obscure complaints must be sought in the condition of the blood. In what exact way all this will lead to successful interference by remedial measures is not yet apparent; but it is not only the experience of the past which animates hope for the future, but the certainty we enjoy that modern improvements in medicine have kept exact pace with the advance made in the study and comprehension of the laws of disease.

Once it is definitely certain that we need no longer grope in darkness for a true and full explanation of what it is that provokes the symptoms of a diphtheritic attack, so soon there will then be marked an era of improvement in the treatment of the disease. Already, indeed, is it evident that reforms must be introduced, and less urgency be attached to local signs while they are not threatening immediate destruction. But in this, as in every similar case, prompt and speedy measures at first are those most surely to be trusted.

SUPERANNUATION OF POOR-LAW MEDICAL OFFICERS IN IRELAND.

THE Local Government Board for Ireland have just issued upon this subject a most important circular letter which we print *in extenso* in the Supplement to the *Medical Press*, which is generally devoted to Irish Poor-law affairs. The subject is, however, of so much general importance that it is necessary for us to epitomise in these columns the nature of the course which the Local Government Board has decided upon, and the opinions which it has officially expressed. The Board—in the first place—takes exception to the manner in which the discretion which Boards of Guardians possess as to the amount of superannuation has been exercised. They point out that, in some cases, “allowances have been proposed which are quite disproportionate to the length of service of the retiring officer, and equal or very nearly to two-thirds of his salary and emoluments, even though his period of service may have been comparatively short.” At the same time the Board “state that they have observed with regret that in some unions the guardians have refused to grant superannuation allowances to old and deserving officers which . . . has induced officers who have become inefficient by reason of age and infirmity to struggle on in their situations when physically unable to discharge their duties.” This statement is, in fact, the official formula for the complaints which we have ourselves repeatedly uttered. Everyone knows that the discretion given to Boards of Guardians has been abused by them, and that, as long as Irish guardians are of the present class, it will continue for a long time to be abused. Everyone knows that the medical officer who is of the right politics—religious persuasion—who has tact enough to make himself useful and subservient to his masters, who has money enough to give a nice little dinner to the Poor-law Guardians now and then, and a select little garden party to their wives and daughters, who makes it a rule not to see nuisances or to smell stench belonging to influential people, everyone knows—we say—that this class of doctor can get his full two-thirds superannuation at any time that it pleases him to

fall ill for a few weeks. On the other hand, everyone knows that the hard-working dispensary alavey, with a large family, a starvation income, an inconvenient conscience, an hallucination that he ought to do his duty, and an incompatibility of religion and politics with those of the majority of his guardians, will have to keep slaving until his mainspring runs down, his wheels wear out, until his very soul is sacrificed with his body to his work, and yet he dare not ask for even the meagre provision for his old age. The Local Government Board are well aware that this is no over-drawn picture, and we thank them for having the courage to say so.

The practical outcome of their consideration of this state of affairs is a determination to fix a scale of superannuation which they will rigidly apply to all ordinary superannuation cases which may, henceforth, arise, beyond which Boards of Guardians may not go and—up to which—we venture to hope, the Local Government Board will endeavour to keep them.

Such a scale was decreed last year by the English Local Government Board, and it is simply an application to the case of Poor-law medical officers of the rate allowed to civil servants of the Crown by the Superannuation Act of 1859—better known as Playfair's Act. “The Board think it expedient to state . . . that, in giving their consent in future to superannuation allowances . . . they will be governed, as far as circumstances may permit, by” the civil service rules. Thus a non-medical union officer, after he has passed ten years of service, may be granted a pension amounting to one-sixtieth of his aggregate emoluments for each of his years of service—*e.g.*, for twenty years, twenty-sixtieths, or one-third; for thirty years, thirty-sixtieths, or one-half; until at forty years the extreme limit is reached, of two-thirds of his full emoluments, after which period no further increase can be allowed. As regards medical or other professional officers, “where, for the due and efficient discharge of the duties, professional or other special qualifications are required,” a number of years, not exceeding ten, may be added, for the purpose of computing the pension, to the period actually served. Thus, a medical officer who has, in fact, served fifteen years may be allowed credit for twenty-five years, and may attain his full two-thirds pension on reaching thirty years' service.

Although the effect of this determination of the Local Government Board is to impose a limit to the amount of Poor-law pensions, to which, heretofore, there was no similar limit, and thus to debar medical officers from receiving the full two-thirds of their emoluments on retirement after short service; nevertheless, we entirely approve of this act of the Board, and we congratulate Irish Poor-law medical officers thereupon.

The scheme thus officially adopted by the Board is, identically, that which was submitted by the Irish Medical Association to the Chief Secretary, and to the Board itself, in the early part of this year. Such an arrangement is, of course, hopelessly imperfect, and of little or no value to the medical officer as long as the guardians continue to be invested with a power to refuse superannuation; and it is to take from them that discretion that Parliament will be asked during the coming session. The principle of the Irish Medical Association has now been

admitted and approved, both by the Chief Secretary and the Local Government Board, and much difficulty is thus removed from its legislative progress; but there is yet much to be done—powerful influences to be met, opposition to be cleared away—and the indolence of our profession to be converted into activity and enthusiasm.

It is quite possible to do all this, and we doubt not that the Irish Medical Association will succeed in effecting the object; but we would earnestly call for the co-operation of medical men throughout Ireland, without which the effort cannot succeed.

ANTI-VIVISECTION FANATICISM.

It is quite useless to argue with the victims of an *idée fixe*, and to try by reasoning to shake their faith in the belief which absorbs them. Whether they labour under the delusion that they are some historical personage long since deceased, whether they are rendered miserable by the ever present thought that most diseases are due to vaccination, or whether they look upon vivisection as a horrible amusement indulged in by certain fiends in human form—albeit qualified physicians and earnest scientific workers—it is all the same, they are beyond the reach of reason, at least on the subject of their monomania. Therefore, we were glad to notice that the recent invitation of the anti-vivisection society to the profession to meet them and discuss the subject of vivisection was entirely disregarded; and we are pleased to notice that the numerous letters which these fanatics have addressed to the newspapers since the failure of their shameful prosecution of Dr. Ferrier have been left unanswered by the profession. These letters have certainly been very provoking in character, containing shameful imputations upon the profession and medical press. Whilst, however, these fanatics are best left individually unanswered, it is necessary that they should be collectively dealt with, and that the unreasoning outcry which they are raising should not be allowed further to excite the minds of a sympathetic, but ill-informed portion of the public. Seeing how the late government in carrying the mischievous Vivisection Act yielded in very truth to mere unreasoning clamour, it behoves us to be careful lest, by a too silent attitude of contempt, we again allow similar means to give rise to measures further restrictive of legitimate indispensable scientific research. It is unfortunate that at this day busy men of science labouring for the good of humanity, should be taken from their work to combat ideas identical in their essence with such as led to persecution of scientific discoverers in the Dark Ages; but, however much we may deplore the fact, we must not ignore it. We trust to see practical steps taken towards the formation of an association of scientific men to counteract the anti-vivisection agitation—to enlighten public opinion and, if not to obtain the repeal of the obnoxious Vivisection Act, to bring such pressure to bear on Government as shall compel them to interpret the Act in the most liberal sense, and to remove every possible obstacle to the free pursuit of science. Such an association may count on our hearty and active support.

Whilst on this subject we would direct the attention of

our readers to the three admirable articles on vivisection just published in the *Nineteenth Century*, for the present month, from the pens of Sir James Paget, Professor Owen, and Dr. Wilkes. Each article is admirable in its way, and it is hard to conceive how any dispassionate reader could, after their perusal, remain unconvinced of the needfulness of vivisection to biological science; or fail to see the necessity for the removal of every obstacle to its legitimate pursuit. We can think of no better means of combatting the exaggerated statements of the anti-vivisectionist than the republication of these articles and their wide distribution among the public; and any funds that may be raised for the purposes to which we refer above, cannot be better employed than in carrying out such an undertaking.

Notes on Current Topics.

Metropolitan Hospital Sunday Fund.

At a meeting of the Council of the Hospital Sunday Fund, held last week at the Mansion House, the Annual Report of the Council was presented and adopted. The collection, this ninth year of the existence of the Fund, was the largest yet made, the total amounting to £31,856. Another gratifying circumstance also was that a considerable increase had taken place in the number of contributing congregations. Of this sum £27,402 went to ninety-four hospitals, and £2,513 to fifty dispensaries, the surgical appliance branch of the Fund getting £840; whilst the working expenses absorbed £1,054—about 3 per cent. of the receipts. The Surgical Aid Society, by deputation, once more appeared to urge upon the Council its claim to participate in the Fund; but it was not entertained, as the Society refused to discontinue its reprehensible practice of compelling the lame, the halt, and the blind to canvass its subscribers for letters equivalent in value to the surgical appliance. On the recommendation, however, of the General Purposes Committee it was resolved unanimously to ask for an increased amount for the purchase of surgical appliances. The cordial thanks of the Council were offered to the clergy, and ministers of all religious denominations, for their valuable co-operation in so successfully pleading the cause of Hospital Sunday before their several congregations. Some inquiry was, it appears, needful, and explanations were asked for, from no less than eleven hospitals and one dispensary, before awards could be made. Three of the same expressed themselves satisfied to leave their cases in the hands of the Committee. This can scarcely be looked upon as a perfectly satisfactory way of adjusting differences, especially so, as it may seem to others as to ourselves—a way of slurring over a difficulty. If we are creditably informed, one hospital has again received an award upon a *written* return of the secretary, whilst no *printed* report whatever has been issued to its subscribers for five or six years past. It is, therefore, somewhat questionable whether the *auditing* contemplated by Rule IV. has actually taken place. We likewise fail to perceive why so large a sum as £506 5s. should have been awarded to the All Saints Convalescent Hospital, Eastbourne, and in

return for which it sends fifty letters only of admission to its benefits—a number far below that provided for by Rule VIII. of the Hospital Sunday Fund. It is scarcely just to a struggling institution, one labouring under difficulties, as the Westminster, which has quite recently been compelled to sell out stock to pay its debts, and but for a disproportionate payment, should, as it well deserved, have received a larger award than it did. We may remark, also, that we are at a loss to conceive why dental institutions should be classed under the heading, "Hospitals," and receive a sum equal to that of the larger dispensaries. We have looked forward with some hope that the Council of the Hospital Sunday Fund would make an attempt to bring about a reform of the abuse of the vast system of hospital eleemosynary charitable relief. In this respect, however, our hopes seem a long way from being realised; for no effort whatever has been made to induce these institutions to act in some kind of concert and upon a well-arranged plan, which would materially relieve them of the imputation of expending their funds upon unworthy and improper objects.

Lung Capacity of Children.

AN interesting series of experiments has been carried out in Russia by Dr. Nagorsky with a view to determine the relative lung capacity of growing children. The observations were conducted on 944 children, 630 of whom were boys, and all in attendance at one or other of the schools in the St. Petersburg district. The results arrived at by Dr. Nagorsky have been described in the *Surgeon*, a Russian medical paper, and the chief conclusions formulated in the article tend to throw doubt on the law of Quetelet to the effect that in persons under 15 years of age the body weight is proportional to the square of the stature. Dr. Nagorsky determines this ratio to be 1.15, and with this number he gives the lung capacity as proportional to 2.4 of the height of the body in boys, and to the square of the height in girls. In respect to absolute weight of the body; the lungs were found in these children to possess a capacity of 65 cubic centimetres in boys, and 57 cubic centimetres in girls for each kilogramme; other observations have been made bearing on the same question, and it is expected that the whole work will, ere long, be issued in a separate form, with additional researches conducted by Dr. Nagorsky.

The Royal Society.

THE anniversary meeting of the Royal Society was held on Wednesday last, Nov. 30th, when the President, William Spottiswoode, D.C.L., delivered the usual address from the chair. In it he described the progress marked by the events of the past twelve months, dwelling especially on the importance of the works achieved by Fellows of the Society. A considerable portion of the address was devoted to consideration of the advances in electrical science signalled by the late Conference of Electricians in Paris, and we are not surprised to find the President of the Royal Society stamps it with his high authority, as the most important gathering of the kind ever held. Referring to the obituary of the year, Dr. Spottiswoode

announced that no fewer than twenty-two British and one foreign Fellows had been lost to the Society through death. Among the former the late Dr. Billing was the most advanced in years. The Government grant of £4,000 per annum for promoting original researches having been given for five years, which have now expired, a report, based on the experience already gained as to its usefulness, has been submitted to the Department of Science and Art, through which the vote is made; and future arrangements, of a modified kind, are looked for as its outcome. During the year 127 papers had been received, many of high importance. Dr. Spottiswoode, referring to the resignation of his post as Secretary by Prof. Huxley, dwelt with satisfaction on the fact that Prof. M. Forster, of Cambridge, had consented to accept the post thus rendered vacant.

Heart on the Right Side of the Body.

A CURIOUS case of abdominal position of the heart in a human subject is related by Dr. J. G. Wiltshire, in the *Maryland Medical Journal* for Nov. 15. The body was one dissected in the Baltimore College of Physicians and Surgeons, and was that of a negro, well-developed, and with no indications of chronic disease as producing death. "The heart was found on the right side, with its base at the proper level, corresponding with the upper borders of the third costal cartilages, with its apex pointing to the right, resting on the diaphragm at a point corresponding with the space between the fifth and sixth ribs. It was normal in size and appearance, and had evidently taken this position in its cavity without any agent to determine the displacement. From the left side of the heart the aorta came off, and in every way behaved as it ought to have done, save in giving off its branches." The *arteria innominata* was wanting, its branches coming off from the arch in the following order: The right common carotid from the upper transverse face of the arch, where it begun to descend towards the third dorsal vertebra; then ascended in front of the trachea dividing at the usual point. The external carotid gave no branches until opposite the symphysis of the chin, when a short axis gave origin to the facial, lingual, and superior thyroid. The internal carotid exhibited no abnormality. The left common carotid came from the outer side of the descending part of the arch, ascending and dividing as the right. The left subclavian arose from the third part of the arch, and prevented no anomalous distribution. The celiac axis arising from the back of the vessel was the only abnormality found in connection with the abdominal aorta.

Defer's Method of Treatment of Simple Hydrocele.

DR. ROL, in the *Bull. de Ther.*, praises this method of treatment, of which he gives the following description: The hydrocele is punctured with canula and trocar, as usual, and evacuated; through the canula is introduced a sound, on the end of which is fused a little piece of nitrate of silver; the interior of the tunica vaginalis is then rapidly touched at different points with this caustic, when the sound, and after it the canula, are withdrawn. The results of this mode of treatment are said to be excellent.

Notwithstanding the occurrence of a sharp inflammation, lasting five or six days, a cure is generally obtained, not by adhesion of the two surfaces of the tunica vaginalis, but by a simple vital modification of that membrane. The return of the effusion is rare. Defer's operation is thus described as perfectly safe, thoroughly efficacious, and easily performed.

Sir James Paget.

UNIVERSAL regret will be felt at the announcement made in connection with Sir James Paget to the effect that the condition of his health is a cause for much anxiety to his many friends. Sir James has been for some days confined to bed with an attack of pneumonia, of a very similar kind to the seizures he has suffered from occasionally since he was laid up with blood poisoning. The worst of this present attack may now be said to be past, and it is hoped that in a short time the distinguished patient may be able to be removed to the south of Europe, where he will in all likelihood pass the winter. Sir James Paget has been attended by Sir William Jenner, Dr. Andrew, and Mr. T. Smith.

Death from Chloral.

ANOTHER death from chloral was recorded in the Coroner's Court last week, the victim having been a young man, recently a student in a Welsh College, and who had been only a short time resident in London, in quest of a situation. The evidence went to show that deceased had been more or less habituated to the chloral habit as a means at first of subduing neuralgic pains. It must be assumed, however, that the fatal influence of the drug grew irresistibly strong, and that this adds another to the long list of deaths from the indiscriminate use of the drug.

Military Hospitals in India.

At last the long threatened recession in the system of military hospitals in India has become a fact, at least as far as the Bengal presidency is concerned. That is to say, station hospitals in India, found unsuitable for military purposes eighty years ago, have been re-established; regimental hospitals then introduced, and which ever since have completely fulfilled their purposes, are now abolished. That this measure is only one of a series in regard to which usages that in bye-gone times had been found unworkable or unsuitable, for their intended purposes have been reverted to, and proclaimed as novelties, is true. Like several others also, its reintroduction has taken place in opposition to the views, and directly against the protest of experienced officers as to the requirements of British troops in that country.

And how do matters progress under the present state of things? According to Indian journals, medical officers, even those trained under the "unification" system, "do not seem to be all of the same opinion as regards the great advantages said to be gained by the introduction of station hospitals, and certainly, as far as they have gone at present, things have not run particularly smoothly." Some of the reasons of this are plain enough to men personally acquainted with Indian cantonments. In the larger stations,

for the most part, every set of regimental lines had its own hospital. In this way, soldiers suddenly seized with one or other of the more rapidly fatal diseases peculiar to the country, as for example, cholera or heat apoplexy, had the benefit of immediate by their own regimental attendance surgeons. Under the present system, in the first place, a medical officer has to be sought for, he living, as he most likely will be, at a distance; having at last been found, and seen the sick man, the latter has then to be conveyed a distance, it may be of two, three, or more miles to the "station" hospital; this, too, during the hottest period of a day in June, while the hot winds are blowing their fiercest. Thus the chances of recovery under treatment immediately applied must, of necessity, be very materially reduced by delay and exposure incidental to the so-called new and improved system. In the cold season these disadvantages will no doubt be less apparent than in the hot; but even then they will not be altogether absent. Another point in regard to which a positive evil to soldiers is threatened by the "new" order of things is this: The statement occurs that "the old pernicious system of men attending hospital, and convalescents in barracks, is strictly forbidden, and now a soldier must be either detained, or admitted into hospital, the only exception being as regards men recently vaccinated." In reference to this, it need only be said that if the framers of such a rule had themselves been personally associated as regimental officers, with soldiers, they would have learned the fact that in India there are, not a few, but many cases of illness in which treatment in, and confinement in hospital, not only cease after a time to be of benefit, but become directly injurious; and others, by no means few, in which a soldier, undergoing tedious convalescence from severe illness, is far more likely to be restored to health in the society of, and among his own comrades in barracks, than he would be in hospital with all its associations of sick and dying men around him, with wretched-looking cold, apathetic native ward coolies, bestowing their very indifferent attentions upon them, the "melancholy punkah" swinging languidly overhead, and, at intervals, sometimes very brief, the "Dead March," telling that one more soldier has gone to his rest. There are other points in regard to "station hospitals," which contain in themselves the elements of failure once again, as such establishments have, on previous occasions, met with in India, and in the United Kingdom.

Amputation at the Hip Joint.

On the 28th ult., Mr. Stokes, of the Richmond Hospital, Dublin, performed amputation at the hip-joint in the case of a young man, who suffered from a large recurrent tumour on the thigh, which had a distinctly traumatic origin. The tumour on microscopical examination proved to be a round-celled sarcoma. Davy's lever was used to control hæmorrhage, and proved as it usually does, effectual; very little arterial blood having been lost. Eucalyptus was the antiseptic employed both during and subsequent to the operation. The progress of the case has so far been most satisfactory, the patient's pulse and temperature having scarcely ever passed the normal standard since the operation.

A Curious Species of Leech.

M. MOURN lately presented to the Société de Biologie a collection of fifteen leeches, of a species foreign to those found in France. They were adhering to the walls of the mouths of horses just returned from the Tunis campaign. They had been camping near Bizerte. All the brooks of Northern Africa contain that kind of leeches, called *hemopsis sanguisuga*, whose jaws are too weak to bite the skin, so that they enter into the animals' mouths when these come to drink, and cling to the mucous membrane. They may live in this situation for weeks, causing hæmorrhages, and even asphyxia, if they enter the larynx. But they die almost immediately when introduced into the stomach or the rectum.

Condensed Milk.

In a communication published by Dr. Voelcker in the Dairy Association's Journal he says that not unfrequently condensed milk is represented to be nothing more or less than new milk evaporated, at a low temperature, to a certain degree, with the addition of white sugar. None of the five samples analysed by him however, were produced from whole new milk, but from more or less skimmed milk. If milk rich in cream is evaporated to a small bulk, even with the greatest care the resulting condensed milk, when mixed with water, draws up oily globules, tastes somewhat rancid, and not so nice and sweet as condensed milk produced from partially skimmed milk. Really good condensed milk, as a matter of fact is always made from skim milk, or from milk unusually poor in cream. However, apart from the greater price of condensed milk, it is not a perfect substitute for new milk either chemically or physically. At the best, most kinds of good condensed milk are milk-syrups, consisting of concentrated skim milk and white sugar.

The Proposed Compulsory Notification of Infectious Disease at Liverpool.

We learn with much satisfaction that, in consequence of the energetic opposition of the profession in Liverpool to the notification clauses of a Bill which was to have been promoted by the corporation of that town, the clauses have been rejected by a majority of nine to four. We warmly approve of the firm stand taken by the profession, and we are quite confident that, if physicians elsewhere make their influence felt in the same way, we shall hear no more of the project to force them to act as detectives or process-servers on their own patients. It is the public boast of the sanitarians who advocate this system, that the notification law for Edinburgh and other places was passed by keeping the movement quiet, and that the doctors knew nothing of the penalties to which they were subjected until it was too late for them to resist. Happily, professional opinion has now grown so strong on the subject that it will not be any longer possible for corporations or sanitarians to steal a march, and we hope that the success of the resistance offered by the Liverpool medical practitioners may encourage the whole of their confrères throughout England to oppose the Social Science Association's Bill, which is so graciously patronised by the Parliamentary Bills Committee of the British Medical Association.

The Blaine Gold Medal.

THE Director-General of the Naval Medical Department, and the Presidents of the Colleges of Physicians and Surgeons of London, to whom is entrusted the duty of awarding the gold medals provided by the bequest of Sir Gilbert Blaine Bart.—have awarded them to Fleet Surgeon Belgrave Ninnis, M.D., St. And., M.R.C.S. Eng., of H.M.S. *Garnet*, and Staff Surgeon Alexander Macdonald M.D., L.R.C.S. Edin., of H.M.S. *London*.

Irish Registration Prosecution.

WE note that the Registrar-General for Ireland has found it necessary to prosecute Dr. Kean, of Newry, for three offences against the Registration Act, he having refused persistently to register the birth of his child; the charges were all clearly proved and fines were imposed. We give the Registrar-General the fullest credit for the firmness shown by him in vindication of the law which it is his duty to administer, and we have no sympathy whatever either with Dr. Kean or any other medical practitioner who lays himself open to the penalties imposed on him. Whatever excuse may be pleaded on the ground of ignorance of the general public for their non-compliance with the law is entirely absent in the case of a medical man, and there can be in his case no explanation of a refusal to perform the simple duty required of him. We do not believe that Dr. Kean will find in Ireland one of his profession either to approve of his proceedings, or to justify him, and, if there be a medical man willing to set the law and the good government of the country at defiance we may leave him to the castigation which it will be the duty of the Registrar-General to inflict on him.

The French Social Problem.

At the beginning of the present century, with a population of not more than twenty-seven millions, there were actually more births in France than took place in the year 1880. M. Legrand, in his well known essay on *Le Mariage et les Mœurs en France*, states that between 1800 and 1815 the number of children born per marriage averaged 4.24; since then it had sunk gradually; and in 1860 averaged only 3.03 for the five preceding years. It rose again until 1865, but has since declined; and in the year 1871, the date of the Franco-German war, reached its lowest depth of 2.28. In 1872 the average rose to its highest for the last few years, namely 2.67, and in 1877 it was 2.55. M. Legrand asserts, on the strongest possible grounds, that this decrease in the birth-rate of his country continues, and is becoming more marked as the years go by. It is a noteworthy and perhaps ominous fact that lately the number of marriages have not decreased. Indeed, there are actually more marriages per cent in France than in England, the average per hundred being in the former '88, and in the latter '86.

THE George Henry Lowes studentship of £300 per annum, tenable for three years, on the condition of the holder devoting his whole time to the prosecution of Original Research in Physiology, is now vacant. Applications should be sent in on or before January 1, 1882, to Dr. M. Foster, Cambridge.

Treatment of Phthisis.

At a meeting of the Société Médicale des Hopitaux (*La France Médicale*) Dr. Debove said that he had had under his care a phthisical patient who became unable to take milk. Dr. Debove decided to feed her with the esophageal sound. He gave her in this way at first a litre of pure milk, then meat and eggs. At length he was able, without causing vomiting, to give her two litres of milk, 200 grammes of meat, and 10 eggs. Singular to relate the patient's appetite returned, she increased in weight 100 grammes a day; she sleeps well and the sweats have disappeared. Dr. Debove has decided to treat all his phthisical patients in the same way. Dr. Dojardin-Beaumez has had similar results.

Hypodermic Injection of Cold Water.

DR. RAYMOND TRIPIER employs subcutaneous injections of aqua fontis to prevent vomiting of food in phthisical patients. For this purpose, he writes in the *Lyon Medical*, he injects into the epigastrium a syringeful of very cold water—either before or immediately after the meal. Under the influence of these injections he has often witnessed the cessation of vomiting which had persisted in spite of appropriate remedies. It appears similarly to stop vomiting in some dyspeptics, and especially in so-called nervous women who dread the use of morphia. It is in these latter patients especially that it is convenient not to let them know the nature of the fluid injected.

Benzoate of Soda in Whooping-Cough.

D. TORDEUS, of Brussels, writes that he has prescribed the benzoate of soda in a number of cases of whooping-cough, and that in all the cases the parents reported that the coughing fits began to diminish in force and frequency after one or two days of treatment. He gives four grains of the salt every hour to a child of two or three years. The drug seems not alone to diminish the force and frequency of the paroxysms, but also to exert a favourable influence on the mucous membrane of the respiratory tract, and to prevent the development of serious pulmonary complications.

THE Public Health Committee of the Corporation of Cork have recommended that a public analyst be appointed at a salary of £100 a year, with a fee of 10s. 6d., for each analysis in excess of £100 made for the Corporation.

OUT of the twenty-five candidates who presented themselves last month for the Fellowship of the Royal College of Surgeons of England, no less than seventeen failed to acquit themselves to the satisfaction of the Court of Examiners, and were consequently referred to further professional studies for one year.

THE Customs duty of 1s. 3d. per pound, levied on chloral hydrate from abroad, was, during the year ending March 31st, paid on 14,361 pounds, amounting to £910. The receipts on account of imported chloroform, collodion, and ether were very trifling, amounting altogether to less than £40.

THE report going the round of the profession and copied into some of the medical journals, that the doctors in attendance upon the late President, have presented their bills in without foundation. No bills have been called for and none have been presented. Probably some one is interested in circulating the report.

A MEETING of two hundred and fifty physicians was held at Copenhagen on November 28, at which a resolution was adopted approving the proposal to hold the next International Medical Congress in 1884, at Copenhagen, and proffering a cordial welcome by the Danish medical profession to their foreign colleagues on that occasion.

DIPHTHERIA would almost appear to be epidemic in Berlin just now, as the number of deaths in that city last week from this malady exceeded those in Great Britain and Ireland combined. It is also very prevalent in Paris and New York, the mortality therefrom being only one less than in Berlin.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of their population, were, in—Wolverhampton 13, Leeds 15, Bradford 16, Newcastle-on-Tyne 16, Sheffield 18, Plymouth 18, Bristol 19, Sunderland 19, Portsmouth 19, Leicester 19, Glasgow 20, Edinburgh 21, Brighton 21, Birmingham 21, Oldham 21, Nottingham 21, London 21, Norwich 21, Manchester 22, Salford 27, Liverpool 28, Dublin 29, and Hull 30.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 28, Bombay 25, Madras 35, Paris 26, Geneva 19, Amsterdam 24, Rotterdam 14, The Hague 19, Copenhagen 20, Stockholm 20, Christiania 18, St. Petersburg 37, Berlin 23, Hamburg 24, Dresden 23, Breslau 27, Munich 28, Vienna 22, Prague 29, Buda-Pesth 28, Naples 28, Venice 32, Alexandria 34, New York 28, Brooklyn 25, Philadelphia 19, and Baltimore 25. No returns were received from Rome, Turin and Lisbon.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

DEATH-RATE OF GLASGOW.—For the week ending with Saturday the 26th ult., the death-rate of Glasgow was 21 per 1,000 per annum. In the corresponding periods of 1880, 1879, and 1878, it was 27, 17, and 26 respectively.

HEALTH OF EDINBURGH.—The deaths in Edinburgh for the week ending with Saturday the 26th ult. were 87, giving a death-rate of 20 per 1,000. While there were 26 deaths under one year, one was recorded as 94. No death from fever was reported, and the southern suburbs were free from zymotic mortality.

HEALTHY WOMANHOOD.—We are glad to understand that Dr. W. L. Reid's lecture on "Healthy Womanhood" has proved an immense success. Several women were carried out of the City Hall in a fainting condition. What an excellent

substitution for Moody and Sankey during their absence from Glasgow? It is understood that there were many "anxious inquirers" as to the physical effects of tight lacing, and that after prolonged admonition they were successfully "revived."

PROFESSOR MACKENDRICK ON VEGETARIANISM.—It cannot be said that Professor John MacKendrick grudges a large portion of his time to the public. His ubiquity is no less surprising than his versatility. He presided on the 29th ult. at the third annual vegetarian banquet of the Scottish Food Reform Association which took place, where all pious and philanthropic movements are inaugurated, in the Christian Institute, Glasgow. In the course of his address Dr. MacKendrick said he was not in practice a vegetarian—a totally superfluous confession, one would have supposed—but he was satisfied that many ate more animal food than was good for them. But vegetarians wasted power in their controversies on this subject. For example, the moral aspect of the question had been severely strained. He could not agree with those who argued that avoidance of animal food would work a revolution in the character of men—that the fierce and warlike would become gentle and docile. Neither did he attach much importance to the anatomical conditions which had been in argument on both sides. The digestive apparatus of a man and of a monkey were very much alike, but their diets might be very different, and it might be added, however, that in all probability the earlier races of human beings lived on fruits and herbs. If our progenitors lived an arboreal life, they probably consumed the same kind of food, fruits, and roots as the gorilla or chimpanzee of the present day. From the purely scientific standpoint, he thought it had been clearly proved that men might live in a state of vigour and do good physical and mental work on a diet derived entirely from the vegetable kingdom. The question was one of digestibility and power of assimilation. And here the art of cooking came in. If by various appliances vegetables could be so cooked as to be assimilated, then there was no scientific reason why a vegetable diet should not be as nutritious as one composed of animal substances.

GLASGOW MATERNITY HOSPITAL.—The now customary inverted amenities of discussion were duly observed at the annual meeting of the subscribers to the Glasgow Maternity Hospital, held on the 29th ult., in the Religious Institution Rooms. Mr. R. R. Grant presided. Mr. Arthur Forbes, secretary, read the Forty-Seventh Annual Report, which congratulated the contributors on the opening of the new hospital. Of the £1,100 required at the beginning of the year for the new building, £400 had already been received, leaving a balance of £700 still to be contributed. The medical report was read by Dr. Sloan, from which it appeared that the number of cases treated in-door was 273, and out-door, 974—in all, 1,247. The mortality among mothers was 3.6 per cent. It would be instructive to know to what this maternal mortality was due. The Chairman moved the adoption of the report. Mr. Donald Munro objected. He said the new building was no better than the old one. He paid a visit to it recently, along with a director, and the atmosphere in one of the rooms, which was overcrowded, was so bad that they could not wait, and ventilation was impossible. They found the patients in bad order, and the wonder was that the death-rate was not higher. From what he saw and knew, he would recommend the poor of the city to shun the Maternity Hospital, and avail themselves of the resources at their disposal at the Western and Royal Infirmaries. It was nothing short of a plague-spot, and unworthy the support of the citizens of Glasgow. Before there was much improvement a great

change must take place in the medical staff. Dr. Leishman, whose appointment afforded him great satisfaction, ought to be asked to recommend a resident medical officer, and then the death-rate would decrease. He moved that the directors' and medical officer's reports be not adopted, because he had no confidence that the death-rate, large as it was, fully represented the facts. The amendment was not seconded. Mr. Munro asked that his protest be recorded. The Chairman said Mr. Munro came forward and made statements which, he had not the slightest hesitation in saying, were, every one of them, direct and utter falsehoods.

GLASGOW ROYAL INFIRMARY APPOINTMENTS.—Dr. W. J. Fleming has been appointed one of the Dispensary Surgeons, and Dr. David Newman has been appointed Pathologist to the Glasgow Royal Infirmary.

THE COLLEGES OF PHYSICIANS AND SURGEONS EDINBURGH.—On the occasion of the bi-centenary dinner, Mr. Imlach, the President of the College of Surgeons, tried hard to rally his hearers round the College, by telling them of the mighty works it had been engaged in during the term of his Presidency. Dr. Haldane, President of the College of Physicians, stated "that the proportion of rejections of the College of Physicians of Edinburgh was higher than that of any of the other Colleges." This statement was greeted with great applause by the collected guests, who were not treated to a reverse side of this glowing picture. The facts of the case, well known to everybody not connected with the colleges, are, that the number of rejections is almost entirely due, not to the severity of the examinations, but to the great inferiority of the candidates, who, as a rule, are composed of the chronics of the London, Dublin, and English provincial schools. It may well be asked why London students should go to the expense of a railway journey and a week's residence in Edinburgh to get a qualification inferior to their own Colleges, and in most cases after failure at them. There are students now in Edinburgh who have passed their anatomy and physiology at the London College of Surgeons, their chemistry at the Glasgow Faculty, and who, having failed hopelessly at the London Final, are going in for the double qualification. This is the kind of material that the Edinburgh Colleges pride themselves in rejecting. Could they do less?

THE NOTIFICATION OF INFECTIOUS DISEASES.—The Littlejohn Bowie case is not yet to be shelved. At a late meeting of the Edinburgh Town Council Mr. Councillor Reid took exception to the employment of a policeman for the purpose of confirming or not the diagnosis of a medical man as to the nature of any cases of disease. Mr. Reid maintained that "if a case of infectious disease occurred in a private family, Dr. Littlejohn's entrance there under Parliamentary powers would be perfectly satisfactory; but anyone coming into a citizen's house in the position of a sanitary inspector," here he was caught up by the Lord Provost that he was out of order. Mr. Reid persisted that, as it was a matter affecting the public health, he should give notice to take up the subject at a future meeting. It appears that the Town Council feel that they have made a mistake, and are anxious to silence all discussion on the subject. One councillor stated that "if Dr. Littlejohn was to go personally and see every case of fever reported, there would need to be not one, but several, medical officers." The question may arise as to the necessity for confirming the diagnosis of the medical attendant by Dr. Littlejohn or his "skilled policeman," unless the authorities are fearful lest the prospect of half-a-crown for every notification

of disease will be too much for the moral strength of the members of the medical profession in Edinburgh.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—At the annual meeting of the Royal College of Physicians of Edinburgh, held on Thursday last, December 1st, the following office-bearers were elected for the ensuing year:—Dr. Daniel Rutherford Haldane, President. Council: Drs. Alexander Peddie (Vice-President), Alexander Kieller, George William Balfour, Andrew Douglas MacLagan, Claud Muirhead, and John Batty Tuks. Examiners: Drs. Bell, Douglas, R. Paterson, Keiller, Haldane, G. W. Balfour, Struthers, Ritchie, Ziegler, MacLagan, Smart, Muirhead, Brakenridge, Wyllie, Andrew, Tuks, Sinclair, Afflock, Russell, Stevenson Macadam, Messrs. Joseph Bell, John Dunca, John Chiene, William Lees, and Drs. Arthur Mitchell and Henry D. Littlejohn. Treasurer: Dr. John Alexander Smith. Secretary: Dr. John Wyllie. Curator of Museum: Dr. Thomas A. G. Balfour. Librarian: Dr. George W. Balfour. Registrar of Applicants for Licence: Dr. John Wyllie.

Literature.

THROAT DISEASES AND THE USE OF THE LARYNGOSCOPE. (a)

In the words of the author, "the aim of this work is to give a brief account of the diseases of the throat, including the use of the laryngoscope and rhinoscope." It makes little pretension to originality, much of the contents being avowedly derived from the writings of other authors, most of whom, especially those of this country, are laid under a tolerably fair amount of contribution, but with just recognition of their claims. References to continental authorities are, for the most part unimportant, and we notice that there is no reference either to Stoerk of Vienna, Fauvel of Paris, Tobold of Berlin, Massei of Naples, Moure of Bordeaux, or to many others who occupy such a prominent position in their respective centres as practical clinicians, that excerpts from their published practice could not have failed to greatly enhance the value of Mr. Hemming's manual without in any way increasing the size, since for English readers frequent and lengthy quotations from the works of such well known British authors as Morell Mackenzie, Lennox Brown, Johnson, James, and Gibb, might well have been omitted. The book however deserves commendation on account of its methodical arrangement and condensation of material.

Chapter II. on the pathology of throat diseases is fairly given, though its scope might, with advantage, have been extended. In the matter of treatment, the author has, as would be expected from his connection with the Central London Throat and Ear Hospital, given due insistence to the importance of constitutional measures, but he has nothing very new to say with regard to topical treatment. The illustrations are all familiar friends.

In conclusion, we have pleasure in recommending this little volume as a guide for students; any one who has thoroughly mastered its contents, should be able to answer an examination question in laryngology; though without the addition of technical instruction, Mr. Hemming would, we are sure, be the first to acknowledge, that, neither this, nor any work of whatever size, would succeed in making the reader a practical laryngoscopist.

Literary Notes and Gossip.

The name of the *Atlanta Medical Journal* has been changed to *The Atlanta Medical Register*. The management has also changed.

ANOTHER new journal has just sprung into existence called

(a) "Throat Diseases and the Use of the Laryngoscope." By Douglas Hemming, F.R.C.S.Ed., formerly Assistant Surgeon to the Central London Throat and Ear Hospital. Churchill. Pp. 120.

The Medical News and Collegiate Herald, it is published in London every Friday at a penny in the interests of medical students.

Northwestern Lancet is the name of a new medical journal published at St. Paul, Minnesota. It contains eight pages, and is issued twice per month at 1 dollar per year. It is edited and published by Jay Owens, M.D.

THE Howard Medal of 1881 offered by the Statistical Society for the best essay on "Gaol Fever," has been awarded to Dr. Frederick Pollard, of Liverpool. The recipient was Cheselden Medallist and Senior Prizeman of St. Thomas's Hospital in 1868, and is a contributor to current medical literature.

A NEW edition of Dr. Henry's little vest pocket companion "Posological and Therapeutic Tables" has been issued by Messrs. MacLachlan and Stewart of Edinburgh. Having noticed fully the previous edition, we need only add that this, which appears to be a reprint of the same excellent little treatise will be found as succinct and useful a guide as its predecessor.

THE announcement of the award of the prize of £200, offered by the Rev. E. Wyatt Edgell for an essay on the "Range of Hereditary Tendencies in Health and Disease," will be made by the adjudicators at the first ordinary meeting of the Sanitary Institute of Great Britain for the session 1881-82, which will be held on this (Wednesday) evening, at 7.45 p.m.

A NEW feature will be introduced into the *Medical Journal of Obstetrics* next year; the quarterly issues of which will be supplemented by monthly sheets to subscribers. Now that the English Obstetrical Journal has ceased to appear the American journal is being energetically pushed in this country by the publishers Messrs. Baillière Tindall, and Cox with every prospect of success. The English Editor is Dr. Robert Barnes.

THE second edition of "Neales' Digest" is announced to appear in July next, and the sterling value of this 'great work will procure for it a hearty and general reception. The labour expended on the production of the book is deserving of the widest recognition, and it speaks eloquently for its usefulness that a re-issue is now demanded. As a record of progress in professional matters the work is unique, and we shall gladly welcome it in its revised form.

THE publication, in a cheap and readable form, of Prof. Owen's great speech at Folkestone on the occasion of unveiling the Harvey memorial, is a happy thought from which we may anticipate much good will follow. With the speech proper is included, also an account of the proceedings of the day, and an engraving of the statue itself. The book is offered to the public at fourpence, and may be obtained from the *Folkestone News* office.

ABOUT twelve months since we announced in this column that "The Equitable Life Assurance Society" of New York and London had invited competitive essays on "Life Assurance," with special reference to its influence in promoting habits of economy, thrift, and sobriety; and the consequent repression of intemperance, poverty, and crime. The prizes offered were a first prize of £100, and £25 for the second best essay. We have much pleasure in congratulating a frequent and valued contributor to this journal, Mr. T. M. Dolan, F.R.C.S., of Halifax, Yorks, upon the success of his essay, he having been awarded on Saturday last the first prize of £100 over 164 competitors.

THE literature of opium has been considerably added to within the past few months, and will be yet further increase by the agitation against the importation and sale of it in various countries that is now being carried on. A number of pamphlets in relation to opium and the opium habit have reached us, and one particularly, consisting of a clinical lecture by Dr. C. W. Earle, of Chicago, deals with the subject in a plain and outspoken manner. It concludes with a set of rules addressed to medical men, the last of which is significant; it urges, "never under any circumstances teach a patient how to use a hypodermic syringe."

THE *Family Doctor* is the name of a new publication which, though "edited by a physician," it is difficult to regard as anything else than a journalistic error. The plan of popularising medicine is a serious mistake, and any medical information, of a desirable or necessary kind for general use, can only rightly be such as to find admission to the pages of hygienic journals and health reviews. The *Family Doctor* fails to convey a favourable impression, either from its literary contents, which are injudiciously selected, or by its advertisements, which, are many of them, such as would be peremptorily declined by the publishers of high class medical journals.

THE current number of the *Nineteenth Century* is chiefly remarkable for containing three admirable essays on the vivisection question from the pens respectively of Sir James Paget, Prof. Owen, and Dr. Wilks. Sir James Paget's paper is a clear demonstration of the superiority enjoyed by vivisection in a comparison of usefulness, following its prosecution on one side, and the humane sports on the other. Prof. Owen takes the opportunity of silencing the utterances of the ignorant crowd who have deluged him with papers and pamphlets since his memorable Folkestone address; and Dr. Wilks contributes an able and logical exposition of the aims and needs for vivisection in extension of knowledge.

A CURIOUS publication, named the *Zoophilist*, which appeared on December 1st, presents two features of interest. It announces on one page that the kidney is supplied by "the fifth pair," the most acutely sensitive in the whole body; and on another it executes the most daring and most disgraceful misrepresentation in support of anti-vivisection absurdities we have ever seen perpetrated by literary wrongdoers. We regret very much that it should be possible for such unprincipled conduct to pass unrecognised by the public it is designed to cheat; however, but for a little space only, we trust, will the tactics pursued by those who trade on the weakness of crowds, and thrive on the donations of ignorant fanatics, be successful.

"THE enterprising Yankee," not content with the moderate cheapness of pirated English medical works, has invented a new method of distributing the work of English brains among American readers. A New York firm of publishers is issuing a "Library of Medical Classics" at prices ranging from tenpence to one and tenpence per volume, and with a fine discrimination, admits into the series only British books. This may be just as a defence of title—although it looks unpatriotic to ignore the "classical" nature of American productions—but it, nevertheless, presses somewhat heavily on our English authors. The volumes already issued are Mr. Henry Smith's "Diseases of the Rectum," price 25 cents.; Dr. Matthews Duncan's "Clinical Lectures," price 30 cents.; and Mr. Berkeley Hill's "Venereal Diseases," price 20 cents.

THE sixth edition of a little work of about a hundred pages, neatly bound in cloth, and which the publishers, Messrs. Goodall, Backhouse, & Co., of White Horse Street, Leeds (who have forwarded us a copy), offer to send gratuitously, to any of our readers on receipt of a penny stamp to cover postage, is likely to have a great demand. The title of the book is "Good Things," it is in fact a compilation of household recipes, for soups, bread, pastry and the like; with hints on cooking, the catering for dinners at small cost, and other matters of interest to housekeepers. Naturally it will be asked how a book of this nature, which must have cost a large sum to produce, can be given away. The answer is simple, and the object perfectly legitimate. Messrs. Goodall and Backhouse are the well known makers of Yorkshire Relish, Baking Powder, and similar household requisites, and many of the recipes show how food can be better and more economically prepared by their use; hence the book is an advertisement of the firm, but at the same time it is an exceedingly cheap and useful pennyworth to the public.

THE annual issue of Smith's "Visiting List for 1882," has been issued in good time for the coming year, and it is we think, as useful and convenient a business note book and pocket companion in practice as any medical man need desire. Its form with column for a record of visits paid, and for obstetric engagements, vaccinations, accounts due

and paid, drugs and instruments wanted, and memoranda, are already familiar to many of our readers. In addition we notice in this issue, the incorporation of *The Pharmacopoeial Companion*, which was published separately in 1877 by Dr. Bartley, as a "pocket remembrancer;" it is a valuable aid to the busy practitioner, inasmuch as the dose is given to every medicine in the British Pharmacopoeia, and the whole of the remedies, both internal and external, are arranged according to their best recognised action. A table showing the equivalents of different Thermometric Scales, and one giving the Period of Incubation of the Eruptive Fevers of our Climate, is also incorporated in this edition.

FROM an interesting article in the December number of *The Leisure Hour*, a good insight is obtained of student life in Modern Athens, and the difficulties the pursuit of knowledge there entails. Not only do many youths pass through the lower schools and gymnasiums up to the University, but the University, being the centre of learning, not for Athens only, but for all the Greek race whether still under Turkish rule or no, and offering an education nearly free to all, attracts to it all ambitious young men from Thessaly, Epirus, the Aegean Islands, and Constantinople itself. Hither they come penniless, but athirst after knowledge, take menial situations, and thus they earn board, lodging, and clothing, while they pursue their studies and attend the university lectures. There are hosts of graduates looking out for Government appointments, and ready meantime to turn a penny by any employment, however humble. The high esteem in which education is held, the large proportion of public funds devoted to it, and the eagerness with which it is sought and acquired, are among the most striking features of New Greece. The people manifest a natural and instinctive love of learning for its own sake, and apart from its commercial value. The learned professions are accessible to all, and to a much greater extent even than in our own country, are they overstocked.

A PAMPHLET on the "Physiological and Therapeutical Properties of Mineral Waters," by Paul Kilian, M.D., (Churchill), is the first of an interesting series on Balneological subjects, and, as such, a little more ambitious than the majority of such productions. Dr. Kilian has practised for many years at Aix-la-Chapelle, and, we are therefore not surprised to find that his ideas are mainly those of the German school. We hope in future he will do more justice to French and English authorities, for even on balneology we can assure him Germany has no monopoly of wisdom. He however does full justice to Cantani, for that able Italian's theory of gout is very fully expounded in this pamphlet. Dr. Kilian speaks of the still imperfect analysis of mineral waters, preventing their action being strictly confined, but he gives us no investigations into their chemical nature, and but scanty excerpts from the analyses of German chemists, without stating their date. A perusal of the new analyses by Prof. Tichborne, which have appeared in this journal during the past two years, would have been satisfactory to the author, and if he carries out his proposal to write further on the subject, could scarcely fail to modify some of the remarks with which he might follow up what he has said. Still we have read this pamphlet with interest, and are especially glad to see Cantani's theory placed so clearly before the English profession.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review, since the publication of our last list, Nov. 16:—"Eczema." By L. Duncan Bulkley, M.D. "The Latin Grammar of Pharmacy." By Joseph Inos, F.R.S. "Transactions of the Clinical Society of London." Vol. XIV. "The Prevention of Stricture and of Prostatic Obstruction." By Reginald Harrison, F.R.C.S.

PAMPHLETS.—The following have been received.—"On Brain Strain." By C. D. Montray, L.R.C.P. "How to Use the Bromides." By G. M. Beard, M.D. "The Communicability to Man of Diseases from Animals used as Food." By Hy. Behrend, M.D. "On the Action of Water upon Lead Pipes." By W. Sedgwick Saunders, M.D. "On the Failure of the Contagious Diseases Act." By the Repeal Association. "The Use of the Ambulance in Civil Practice." By R. Harrison, F.R.C.S. "On Excision of the Tongue." By Walter Whitehead, F.R.C.S.

THE CROWN REPRESENTATION FOR IRELAND IN THE GENERAL MEDICAL COUNCIL.

DR. LYONS, M.P. for the city of Dublin, and Physician to the Richmond Hospital, has been appointed to the vacancy as Crown Representative for Ireland, caused by the death of the late Dr. McClintock. The selection made by Lord Spencer will be universally approved, Dr. Lyons' claims as a member of the profession being as deserving of recognition as the political position which he occupies in Ireland.

THE PROFESSORSHIP OF ANATOMY IN THE IRISH COLLEGE OF SURGEONS.

At the last meeting of the Council of the College a decision was arrived at of much importance to the medical school of the College, and indirectly, to anatomical and surgical teaching in Ireland. The object of the resolution adopted, was to obtain for the College school, at the next vacancy in the professoriate of Practical Anatomy which might occur, the services, so to speak, of a specialist in anatomical teaching with the view of ultimately amalgamating the two Professorships of Practical Anatomy which now exist, and thus placing the Anatomical Lectures and Dissecting Room Management under the responsible charge of one Professor who would have no other employment than the discharge of the duties of the office.

It was, therefore resolved by the Council,

1. "That it is desirable the two chairs of Descriptive and Practical Anatomy in the College School should be amalgamated, and that in filling any vacancy that may occur, in either, arrangements be made with this view."

2. "That when a vacancy shall occur in either of the Chairs of Descriptive and Practical Anatomy, the Council shall make it a condition in filling the same that the person appointed shall not hold any Hospital or Dispensary appointment, nor engage in private practice or private teaching, or any occupation that would, in the opinion of the Council, interfere with his devoting his energies and attention to the interests of the School."

In addition to the decision expressed in these resolutions, the Council has determined that the Professor thus to be appointed when a vacancy takes place, shall act as Assistant to the Professor of Physiology for the teaching (during the Summer Session) of Histology and Practical Physiology, the study of which subjects has been decreed by the New Scheme of Education and Examination, recently adopted by the College. It is stated that the emolument of the new Professoriate will be at first about £600 a year, after a year or two about £800, and eventually about £1,100 a year, which scale of remuneration will, we hope, be sufficient to attract skilled anatomists and energetic teachers as competitors for the chair.

We are gratified to learn that it is the intention of the Professors of the School to follow the example set them by the Professors in the School of Physic at the University of Dublin, by abolishing for ever the pernicious system of "credit fees," as far as the College School is concerned. Heretofore, the payment of fees has been in nine cases out of ten, postponed by the student or by the apprentice-farmer until the certificates were required to be sent in before the examination, the consequence of which arrangement was, that in all cases in which the student, from one cause or other, did not offer himself for the examination, the

lecturers received no pay whatever for their instruction of him. The loss thus sustained by them has, we believe, been not much less than 25 per cent. of their entire professional incomes, and it is only surprising that, under such circumstances, the "tick" system has been so long allowed to continue.

It will be necessary, in order to carry out the intention of the Council, to obtain the assent of the Home Secretary to a trivial alteration of the College bye laws, but we anticipate no difficulty about this.

Correspondence.

PROFESSOR LISTER ON "TRANSFUSION."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your report of my description of an operation for transfusion, given at the last meeting of the Clinical Society, it is stated that I advised the use of defibrinated blood; whereas what I desired to recommend was a simple and safe method of transforming normal or undefibrinated blood.

This mistake, which I fear may have been due to want of perspicuity on my part, is of so much importance that I trust you will allow me the opportunity of correcting it in your columns.

Your, &c.,

Nov. 30, 1881.

JOSEPH LISTER.

NOTIFICATION OF INFECTIOUS DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of November 16th you allude to a recent case in Edinburgh. As the account of it, with which you have been furnished, is inaccurate, I beg to trouble you with the following particulars.

An anonymous letter reached me, stating that there were several cases of typhoid in a certain house. As this might have been a malicious hoax, I sent one of my inspectors to ascertain whether illness of any kind existed in the house mentioned, and if a medical man were in attendance, and to ascertain his name. The inspector reported that he found several cases of fever in a single bed, that they were without a nurse, and that the neighbours were loud in their complaints. He ascertained from the mother, who was ill, the name of her medical attendant, to whom I at once wrote. In a few days I received an answer, virtually allowing that the cases were fever, but stating that he had conscientious scruples against reporting such cases. I then gave him further delay to consider his position, as he said he was ignorant of the special provision of the Act of Parliament. As I did not hear again from the gentleman the case went to trial.

By a commendable provision in our court practice, if a person pleads not guilty to any charge the trial is at once postponed, to allow full time to prepare his defence. When the medical practitioner heard the charge he said it was all a mistake, and that he was prepared to prove it to be so. It was then considered advisable by the Public Prosecutor that I should see the cases, and be prepared to speak as to their nature. Up to that time it had been anticipated that ignorance of the special enactment would have been pleaded, and that the case would have been settled by the practitioner being cautioned to be more careful in future.

On his second appearance in court, a plea of not guilty was again made; and my inspector had to speak to his obtaining the name of the medical attendant. He was, thereupon, subjected to a cross-examination as to the nature and diagnosis of fevers—a subject on which he was not qualified to speak; but in Scotland, as, I have no doubt, in Ireland, a witness is bound to answer any questions that may be put to him.

In consequence of this cross-examination by the defendant, you have been led to believe—1st, that "the usual proceeding in Edinburgh is to send a police-officer to confirm or not the diagnosis of the medical attendant;"

and, 2nd, that "it was on the strength of the policeman's diagnosis that the prosecution was commenced."

The first is so ludicrous a misstatement that I content myself with saying that such a proceeding would not be tolerated for a moment in Edinburgh; and as to the second, the sanitary inspector, as I have shown, was not sent to diagnose a case of illness, but to ascertain the name of the medical attendant; and the letter from the latter gentleman was the basis of the prosecution.

The question of the compulsory intimation of infectious diseases is one of great importance, and demands the fullest investigation and the freest criticism; but I submit that this solitary case of refusal tends to prove the great success which has attended the experiment which has been carried on in Edinburgh for the last two years, during which period upwards of 9,000 intimations have been sent in to this office—the profession here legally obeying the provisions of the Act of Parliament.

Not a whisper has reached me of any dissatisfaction of my medical brethren with the manner in which the Act of Parliament has been carried into execution. With a free medical and local press, it is not likely, if such proceedings take place in Edinburgh as you have been led to believe, that your readers and the public should not, long ere this, have heard of them.

I have only further to add that the case in question was not appealed, and that, since the decision, the medical man has regularly reported his cases to this office.

Yours, &c.,

HENRY D. LITTLEJOHN, M.D.,
Medical Officer of Health.

Public Health Office,
Police Chambers, Edinburgh.
15th Nov., 1881.

[Dr. Littlejohn, it will be observed, admits—

1. That he sent the policeman to the patient's house.
2. That the said policeman "reported that he found several cases of fever."
3. That the medical practitioner was prosecuted not because *prima facie* guilt was brought home to him by a proper official inspection, but because of something he himself wrote, which something is not forthcoming.

We do not think that Dr. Littlejohn has much improved his position, for it seems to us that the proceedings which he admits, are nearly as objectionable as those he denies.

It is not, we submit, usual or desirable to prosecute anybody on the strength of a supposed admission of guilt, and it is obvious that if Dr. Bowie had omitted to answer Dr. Littlejohn's letter, the only evidence against him would have been the diagnostic policeman.

Dr. Littlejohn congratulates himself that this is "the solitary case of refusal," but is it not also "the solitary case" of successful prosecution? Have not all such prosecutions failed elsewhere, and would not this also have failed if Dr. Bowie, instead of calling books as witnesses, had called persons?

The whole question was one of disputed diagnosis. Dr. Littlejohn (who did not see the cases during sickness) said they were typhoid, Dr. Bowie (who did) said they were not; Dr. Bowie called no witnesses to support his diagnosis, and the Sheriff, therefore, preferred the official opinion of Dr. Littlejohn and condemned Dr. Bowie, a pleasant example for any physician who may chance to differ from a medical officer of health as to what his patient is sick of. In any case, with such examples of prosecution as this before us, it is quite useless for Dr. Littlejohn, or the sanitarians, to call to the physicians, like little pigs, to "come and be killed."—Ed. M. P. & C.]

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to forward a copy of a letter addressed by me to-day to the Chairman of the Liverpool Health Committee

with reference to Dr. Ransome's letter to him published in your last issue. I beg you will have the kindness to insert it in the *British Medical Journal*.—Yours, etc.

A. H. JACOB, M.D., F.R.C.S.I.

23 Ely Place, Dublin, November 26th, 1881.

[Copy.] 23 Ely Place, Dublin, November 26th, 1881.

"To the Chairman of the Health Committee—Sir,—I notice in the *British Medical Journal* of this day, copy of letter addressed to you by Dr. A. Ransome, respecting proposal to make notification of infectious disease compulsory in Liverpool. Not having before me the proceedings at Liverpool which gave occasion for this letter, I am at this moment unable to discuss them, but I hasten to controvert one or two of Dr. Ransome's statements. He says that 'at the last meeting of the British Medical Association at Ryde, the manifest favour with which the plan was received proved that no alteration has taken place in the general approval of the profession.' As a member of the British Medical Association present at that meeting, I assert—1. That the general approval of the profession is a complete myth; 2. That the great majority of the working men of the profession in England neither know of, nor understand the proposed notification system; 3. That the effort of the Social Science Congress at that meeting to obtain approval of direct compulsory notification was outvoted by a large majority; and 4. That discussion and inquiry was at that meeting peremptorily quashed by the chairman, and that a *pro forma* vote was taken in a violent hurry, without adequate debate, and without any understanding of the matter by those present. As I warmly sympathise with the objections to the proposed notification system urged on behalf of the public and the profession, I think it my duty to remove from your mind any misapprehension which may exist as to the attitude of the great body of medical men in reference thereto.—I am, sir, yours truly,

"ARCHIBALD H. JACOB, M.D. F.R.C.S.I."

THE ST. BARTHOLOMEW'S HOSPITAL INQUIRY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—At your request that I should furnish the profession with my post-mortem notes and impressions of the case of Dr. Booth, about which so much interest has been created. I beg to submit the following:—A medical man, Dr. Sherrard, having charged St. Bartholomew's Hospital with mainly causing, or, at least, accelerating, the death of Dr. Booth, a surgeon, this is the sum and substance of the finding of the coroner's jury—death from natural causes, injudicious method of removal to hospital, delay in reaching the ward, with the contradiction of every attention on arrival there. A porter always on duty at the gate is the sage suggestion of these lay arbitrators. Who is responsible for this impotent and abortive climax to an impotent and abortive assault? Not the worthy coroner; Mr. Langham's charge to the jury would have equally graced a medical lecturer or the president of any forensic assembly. Not the hospital—the refutation was as complete as it was substantial. Dr. Duckworth, Dr. Smith, Mr. Spicer, a Bartholomew's student, a lady superintendent, two nurses, and two porters, all gave admirable evidence with a candour compelling credence. The hospital defence and cross case was conducted by Mr. Cross, barrister-at-law, the official representative of the hospital, with the highest professional skill and acumen. Who or what then was responsible for so equivocal an ending? The responsibility is a mixed one. Dr. Sherrard, as the original and only complainant, must bear the full responsibility of the method of this inquiry. Even if one assumes, for the sake of argument, that Dr. Sherrard had reached an absolute conviction that culpable negligence had been shown, such assumption will not help to justify the method of redress adopted. The venue for his appeal was obviously the governing or medical council of the hospital. When this protest had failed to satisfy, it would have been ample time to force the lay press to place the discussion before the ignorant poor. For their benefit hospitals exist; and as natural a whet to their recognised prejudice against hospitals, as the preferring of a charge by a medical man must do incalculable harm. Dr. Sherrard cannot possibly be ignorant of the glorious part St. Bartholomew's and all hospitals play in philanthropy, nor of the difficulty of discharging their invaluable offices under the most favouring conditions. His case was, at his own estimate,

an abuse of function and a failure of administrative organisation. Could a lay jury be expected to grasp such an issue? Could the publication of such details benefit the deceased? Could such publication fail to do incalculable injury to the suffering poor? I repeat then that acquitting Dr. Sherrard of any unworthy motive (such as the yearning for notoriety at the expense of a world-renowned temple of his art), assuming him fully imbued with the feelings of injury and indignation, he stands convicted of a gross blunder and an inexcusable error of judgment. But having prefaced thus much, something may be added in Dr. Sherrard's defence, and in support of a divided responsibility. Dr. Sherrard accepted unchallenged the diagnosis of those in charge of this patient until his admission, Dr. Cliff and Dr. Cassidy. Dr. Cliff was conspicuous by his absence from this inquiry. Dr. Cassidy was present throughout it, until at least the issue was being reached. Dr. Sherrard had the courtesy to publicly admit himself satisfied with my evidence, after Dr. Cassidy vainly appealed to the students and then Dr. Duckworth against it. He also faced alone an undivided audience to the bitter end, and as he stood alone before a large body of students, whose *esprit de corps* made them regard the charges as personal which maligned their alma mater, and directly inculpated so justly valued a member of the staff as Dr. Smith, one could not help devoutly wishing his perseverance and determination had been shown in a worthier cause. Dr. Sherrard's bearing throughout the inquiry contrasted favourably with his quasi-supporter, Dr. Cassidy. Dr. Cassidy opened his evidence by announcing he was not a co-complainant, and concluded it by refusing to associate the hospital with the cause of death, even to the minor extent of acceleration, but between these points he barked loudly behind the fence. He was at pains to inform the Court that he considered and had denounced the hospital treatment as monstrous; he admitted having "bullied" an official of the hospital. On uncontradicted evidence he is alleged to have sworn before the female officials of the ward, and in the hearing of his dying friend: "If he dies, by God I'll have an inquest." The coroner's mild sarcasm, that such conduct does no good and is not to be expected of medical gentlemen, does not err on the side of severity. As a medical man he will be condemned in this for nigh as gross a *lache* as his failure to examine the urine of a patient he had known for years and treated for days, and who was discovered to be passing half albumen by "a bit of a boy." (Dr. Cassidy's description of Dr. Smith to the lady superintendent of the ward). The vulgarity of an oath before female witnesses and a dying man speaks for itself as a social outrage upon gentlemanly usages.

Dr. Smith in his evidence pointed out the insult to the profession in limiting operations to hospital surgeons. He truly said the surgeon who could not do tracheotomy ought to be ashamed of himself. My evidence on this point was demanded. I gave it reluctantly, because I felt in exposing such flaws in brother professionals I was doing our common profession hurt; but forced to speak, I tried to speak frankly, and I have to thank your journal and the learned President for most generous allusions to my examination. I assured the Court that tracheotomy had been performed by students and with a penknife, and as an operation whose performance was often demanded instantly, I further declared that assuming oedema of the glottis to have existed to an extent justifying tracheotomy, to talk of it as being possibly needed at any moment is to reveal as gross an ignorance of the theory of surgery as inability to operate reveals an ignorance of its practice. If demanded, it is demanded instantly, another spasm is not to be waited for, and no delay for removal or other reason can be justified. This disposed of a gratuitous assertion that Dr. Booth's residence was unfit for operation. Here I ask leave to pause to say one word on this subject. The coroner well said that the evidence proved the good people with whom deceased lived to have shown him devoted attention. It is one of the results of this wretched trial that these poor people have lost all their lodgers, because it was stated that deceased had had no solid food for three days; the folly of associating those who gave him the tenderest care with such a fact (the more when brother professionals were in constant attendance upon him), is only of importance from the gross injustice of its consequences. I was further obliged to depose to my opinion as to the existence of oedema of the glottis. I denied its existence to an extent justifying tracheotomy or endangering life. I submit to the profession now my grounds for this assertion. That oedema may disappear on post-mortem I granted as a possibility but

that oedema can exist with no evidence in the throat to touch or sight during life when viewed through the mouth, with a sudden cessation of the spasms during the few minutes drive to hospital, with death there by assthenia in twelve hours, and without a single spasm, I declared impossible. Further, that spasms which may have occurred in this case were due to oedema glottidis I refuted as an unphilosophical deduction in view of such obvious causes for reflected spasm or its occurrence in the bronchi as double pleurisy of the renal type (tripe-shred lymph without effusion). One old pleural adhesion, emphysema and oedema of the lungs (bronchitis). No consolidation (deposed to by Dr. Cassidy). Hypertrophy of the left ventricle (possibly compensatory), atheroma of the aorta, and general venous congestion. It is perhaps convenient I should here complete an outline of the post-mortem appearances:—The dura mater adherent, a soft spot in the left hemisphere, anterior to corpus striatum, the same venous engorgement which was well marked in every organ, including the right heart (grumous blood), but not the pulmonary artery (damaging the assumption of death by suffocation anticipated by complainants and denied by hospital). The larynx had distinct traces of old specific ulceration and cicatrices; it was naturally large, and cracked like bone. No evidence of acute inflammation (diagnosed by Dr. Cassidy). A circlet of ulcers round the epiglottis, and some trifling active congestion there with a trace of oedema of glottis (perhaps due to the painting of the throat by Dr. Cliff). Conical projection of the liver superiorly, due to fatty enlargement, with perhaps incipient cirrhotic contraction at the base, and an old adhesion to right side, with a deep sulcus (probably from syphilitic gummata), congestive spots on the surface (not deep). A large stomach (empty), as were all the intestines, these latter being markedly friable. A spleen overloaded with venous blood (period from death, fifty-four hours, left this organ and others in a doubtful condition). The large fatty kidneys of chronic Bright's disease. Traces of old peritonitis. A thickened bladder.

Fatty degeneration almost everywhere. The valves of the heart were marvellously healthy, and the brain vessels seemed free of the atheroma.

The item in the verdict which admits a delay in the surgery is a travesty on the weight of evidence, I do not attempt to understand. For this delay in the surgery the jury had but the unsupported testimony of the complainant. The house physician was already with the patient before Dr. Cassidy had concluded the "bullying" of the porter described in his own evidence. Dr. Sherrard, the complainant, made a second charge as to delay in the ward, but withdrew it, admitting a necessary error of thirty-five minutes, his times being recorded on a watch, for whose accuracy he will not vouch. Against the reputed delay is a perfect phalanx of evidence. Porters, nurses, students, and physicians all in exact accord, and proving *exceptional* rapidity of conveyance to the ward, as was naturally to be looked for in a moribund case, and to one with the claim of professional brotherhood. Three minutes after arrival the patient was in the surgery; ten minutes afterwards in the ward. He himself never complained of the hospital. He was supplied with a cleric—all left to be done for him. He did resent tracheotomy, proposed by his previous advisers. He complained of his back—the autopsy shows with what good reasons. An indiscreet visit to an out-door closet the day of removal to hospital, a not perfectly judicious mode of life and specific mischiefs, are accelerations to death for which the evidence revealed the deceased responsible.

Yours truly,

CHARLES D. MOUTRAY.

NOTICES TO CORRESPONDENTS.

DR. KNOTT (Mayo).—Your communication is marked for early insertion.

THE WIDOWS AND ORPHANS OF MEDICAL MEN resident within a radius of twenty miles of London are notified by advertisement in another column that all applications for participation in the funds of this charity must be made to the Secretary before Dec. 20th.

A COUNTRY PRACTITIONER will probably find Dr. Haberahon's "Diseases of the Stomach, their Diagnosis and Treatment," of value to him."

AUTHOR.—The book is laying on our table and will be reviewed in turn with others.

A JUNIOR.—We hardly know which to advise; "Smith's Visiting

List" and "Letts's Medical Diary" are both good; some prefer the arrangement of one, and some the other.

THE COLLEGE OF PRECEPTORS.—We understand that there are no less than 7,500 candidates for the half-yearly certificate examination of this College, which opened yesterday. This is the largest examination which has ever been held in this country by any examining body, and, taken in connection with the various university local examinations, which attract about 10,000 candidates annually, furnishes a striking evidence of the great extension which the system of middle-class examinations has now attained. The higher certificates of the College having been recognised by the General Medical Council, as guarantees of a good education, exempting the holders of them from the preliminary examinations of the various medical corporations of the United Kingdom. The College has arranged for holding two supplementary examinations, in March and September each year, for these higher certificates, which will be open to medical students.

A PROVINCIAL FELLOW.—Sir James Paget was so decidedly better upon inquiries at the time of going to press, that hopes are entertained that he will be strong enough in a day or two to bear removal to the south of France. We sincerely hope that this pleasing outlook may be justified by events.

QUESTIONS.—The drug fully deserves the encomiums that have been passed; in our hands it has answered admirably.

DR. H. J. M.—We will make inquiries, and, should your suspicions be well founded, will deal with the subject in our next.

M. OR N.—We are not personally acquainted with the author, but, from what we hear, should imagine him to be an honest man, one who thoroughly believes in the opinions propounded.

A HOSPITAL SUBSCRIBER will find a satisfactory reply to his queries in the letter of Dr. Moutray in our present issue.

SURGEON-MAJOR HOGG.—Many thanks.

MR. J. E. R.—It is, as reported, that the first issue of the Transactions were swallowed up as soon as issued, and that a second is in the press to supply so unexpected a demand. We cannot vouch for the truth of this report, in fact, we have reason to doubt it.

A LAY READER.—The pay system at hospitals, though good to a certain extent, is liable to gross abuse, and the subversion of charitable endowments to the purposes of the rich is not a little to be feared.

DOCTORS' DOORPLATES IN AMERICA.—We take the following from a Canadian contemporary:—"Anent doctors' signs," the *New York Record* says, "the brazen sign is large; it covers the whole door-post, it stretches from window to window; its lettering is brilliant, and it is set off with scroll-work in the corners; the passer-by sees it, and cannot but read it; small boys shout out the name as they go by, and adults mutter it over till they reach another block. It is judiciously placed so that the street-lamp illumines it at night. It affects the more public ways, and it indicates the astute and enterprising physician. He is one who maintains a dignified equipage between the code which says, 'Thou shalt not advertise,' and the Bible which says, 'Let thy light so shine.' In these days, when aestheticism is in the ascendant, when every man of thorough culture lunches at least once a week on the sight of a lily, it would be strange if a love of the beautiful did not affect the style of that corner slab of modern civilisation—the subject of this discourse. The aesthetic sign, in its supremest development, consists of a black marble slab, in which the physician's name is carved and gilded. When especially "intense," the letters are old Roman, with golden punctuation marks, which delicately suggest to the looker-on that he should come to a full stop."

HERNIA (INGUINAL).

The following lines, sent us by an Edinburgh (fourth year's) student will probably interest some of our younger readers:—

Of this, two forms you will find—
Namely, the "Oblique" and "Direct,"
From parts in which they are confined,
They form, at sundry times, project.

The former down a canal pass,
"Inguinal," thro' internal ring,
"External," and to scrotum, pass
Obliquely the way canalising.

The latter is called "Direct"
Escaping thro' a triangle
"Hesselbach's," to exit effect
Thro' external ring, or strangle.

Their coverings please bear in mind
In many ways are just the same,
If you take them as here you find,
You will easily mind their name.

Three fascia, one tissue and sac,
Skin—"Direct" has a muscle more,
In the bargain a tendon pack,
And that puts us right on this score.

The difference you must master
Between "Oblique" and the "Direct";
In "Oblique" you have Cremaster,
But "Conjoined Tendon" in defect.

N. P. M.

N.B.—The "external and internal rings" are the abdominal.

A. W. W.—In our next.

THE SOCIETIES.

SANITARY INSTITUTE OF GREAT BRITAIN.—This evening (Wednesday), at 7.45 o'clock, Dr. Alfred Carpenter will deliver the Inaugural Address.

HUNTERIAN SOCIETY.—This evening, at 7.30 o'clock, Council Meeting.—8 o'clock, Dr. Francis Warner, "On a Case of Empyema treated by Antiseptic Drainage."—Dr. F. C. Turner, "On a Case of Cerebral Hemorrhage."

EPIDEMIOLOGICAL SOCIETY OF LONDON.—This evening, at 8 o'clock, Dr. Cobbold, "On *Filaria Sanguinis Hominis*," sent by Dr. Wykeham

Myers, Formosa; followed by a short paper of his own on the same subject.

OBSTETRICAL SOCIETY OF LONDON.—This evening, at 8 o'clock. Specimens will be shown by the President, Mr. Thornton, Dr. Percy Boulton, Mr. Outhwaite, and Dr. Herman.—Dr. Godson, "On Five Cases of Spasmodic Dysmenorrhoea associated with Sterility, successfully treated by Dilatation with Graduated Metallic Bougies."—Dr. Herman, "On a Case in which Dilatation of the Cervical Canal was followed by Removal of Sterility."—Mr. N. W. Jastrebau, "On the Normal and Pathological Anatomy of the Ganglion Cervicale Uteri."—Dr. W. S. Playfair, "On Trachelo-rhaphy, or Emmet's Operation."

LONDON PHARMACEUTICAL SOCIETY.—This evening (Wednesday), at 8 p.m., the following papers will be read:—"Proximate Analysis of the Fruit of *Omphalocarpum procera*," by W. A. H. Naylor, F.C.S.—"The Antiseptic Properties of Cinnamic Acid," by J. B. Barnes, F.C.S.—"Note on *Hedyosmum Nutans* and *Critonea Dalca*," by E. M. Holmes, F.L.S.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Thursday, Dec. 8, at 8.30 p.m., Mr. E. J. Fry-Smith, "On a Case of Glaucoma cured by Esarine."—Dr. Gowers: (1) "On a Sequel to a Case of Cerebral Tumour;" (2) "On Two Cases of Optic Neuritis in Chorea;" (3) "On a Case of Axial Neuritis and Spinal Disease;" (4) "On a Case of Hemiplegia in Locomotor Ataxy."—Mr. G. E. Wherry, "On a Case of Paralysis of the Fifth and Facial Nerves in a young Child."—Dr. Stephen Mackenzie, "On a Case of Acute Vascular Disease with Retinal Hemorrhages."—Mr. Nettleship, "On a Case of Diabetic Cataract."—Mr. W. E. Fitzgerald, "On Unilateral Exophthalmos"—Living Specimens at 8 o'clock.—Mr. Miles: General Retinal Ferriarthritis. Mr. Nettleship: (1) Cystic Tumour of the Eyebrow; (2) Diabetic Retinitis. Mr. Cowell: Cases of Retinitis Pigmentosa.

BARVEIAN SOCIETY.—Thursday, Dec. 8, at 8.30 p.m., Second Harveian Lecture: Dr. Alfred Meadows, "On Menstruation and its Derangements."

CLINICAL SOCIETY OF LONDON.—Friday, Dec. 9, at 8.30 p.m., Mr. W. H. Bennett, "On a Case of *Talipes Equino-varus* treated by Resection of a Portion of the Tarsus."—Mr. J. E. Lunn, "On Two Cases of Myxodema, Male and Female."—Dr. Cavalet, "On Two Cases of Myxodema."—Mr. W. H. Keasteven, "On a Case of Unilateral Exophthalmos" (patient will be exhibited).

Vacancies.

Ballina Union, Crossmolina Dispensary.—Medical Officer, Salary, £120, and £20 as Medical Officer of Health. Election, Dec. 23 (See Advt)

Beckett Hospital, Barnsley.—House Surgeon. Salary, £160, with board. Applications to the Hon. Sec. before Dec. 16.

Lincoln General Dispensary.—Resident Medical Officer. Salary, £150, with board. Applications to the Secretary by Dec. 14.

Middlesex County Lunatic Asylum.—Assistant Medical Officer in the Male Department. Salary commencing at £160, with board. Applications to be made on printed forms to be had of the Clerk.

Sunderland.—Medical Officer and Public Analyst. Salary, £300. Immediate application to the Town Clerk.

University of Edinburgh.—Examinerships in Clinical Medicine, Surgery, Physiology, Materia Medica, and Pathology. Applications must be lodged with the Secretary to the University Court before Jan. 16.

Appointments.

PITTARD, M., M.B.C.S.E., Assistant Surgical Officer to Charing Cross Hospital.

SUTTON, S. W., M.B.Lond., L.R.C.P., M.R.C.S., Senior Assistant House Physician to St. Thomas's Hospital.

TIBBLES, W., L.R.C.P., L.M., Medical Officer of Health to the Rural Sanitary Authority of Helton Mowbray Union.

WELLS, A. K., L.R.C.P., M.R.C.S., Junior Assistant House Physician to St. Thomas's Hospital.

WHITE, E. F., M.R.C.S., Assistant House Surgeon to St. Thomas's Hospital.

WIGAN, C. A., Assistant Medical Officer to Charing Cross Hospital.

WILLIAMS, E., L.K.Q.C.P.I., Consulting Surgeon to the Wrexham Infirmary.

Births.

BUCKLE.—Nov. 29, at Great Bardfield, the wife of John Buckle, M.E.C.S., of a son.

WALSH.—Nov. 26, at Jersey, the wife of Surgeon-Major Walsh, A.M.D., of a daughter.

Marriages.

KANE—CARDEW.—Dec. 1, at St. Andrew's Church, Bath, J. Seymour Kane, B.A., M.D., of Almonbury, to Emma, eldest daughter of Inspector-General G. S. Cardew, M.D., of Bath.

Deaths.

BLAKE.—Nov. 24, at Bishopstone, Moseley, Valentine Walsham Blake, F.R.C.S., late of Birmingham, in his 64th year.

GREEN.—Nov. 29, at the Borough Lunatic Asylum, Birmingham, Thomas Green, M.R.C.S., aged 81.

JOHNSTON.—Nov. 29, at his residence, Huskisson Street, Liverpool, John Johnston, M.R.C.S.E., &c., aged 80.

MAHON.—Nov. 25, at The Hermitage, Crossmolina, co. Mayo, after a short illness, Dr. Thomas Mahon, aged 39.

MILLER.—Nov. 23, at Camberwell New Road, Dr. David Graham Miller, Fleet Surgeon, B.N., in his 81st year.

PHILLIMORE.—At Sneuton County Asylum, Nottingham, Wm. Phillimore, M.B. Lond., aged 60.

POLLOCK.—Nov. 26, at Rose Hill, Hornsey, Timothy Pollock, M.D., late of Hutton Garden, London, aged 83.

STRIDE.—Dec. 3, at 72 High Street, Sheerness, Edward Stride, M.R.C.S., aged 58.

MENSTRUATION AND ITS DERANGEMENTS.

By ALFRED MEADOWS, M.D., F.R.C.P. &c.,

Physician to, and Lecturer on Midwifery and Diseases of Women and Children at, St. Mary's Hospital.

Abstract Report of Harveian Lectures for 1881.

LECTURE II.

DR. MEADOWS prefaced his second lecture by a brief review of the main facts dealt with in the first discourse, particularly insisting on the importance of the ovaries, as shown in the nervous and vascular supplies to these organs. The second lecture, he observed, would be devoted to consideration of the derangements to which the menstrual function was subject, and to the treatment of them suggested by a due appreciation of anatomical and physiological data; the principal points of the lecture are included in the following synopsis:—

A study of the subjects already fully described in Lecture I. will materially assist the interpretation of problems connected with the pathology of deranged menstruation, the point of especial significance being the nervous and vascular communion existing between the ovaries and fundus uteri. Some classification of the derangements to which the function is subject, is called for as an aid to its study, and this may be based either on anatomical data; or on distinctions of origin as "organic" or "functional;" or it may be made to follow deviations in the amount of (1), discharge, and (2), pain attending the periodical menstrual disturbances. Diagnosis, the vital aid to treatment in all these cases, will be little assisted by classification depending on either anatomical or merely descriptive distinctions, but it will derive the most useful and instructive help from that which is founded on the variability of the discharge and its attendants; this mode, therefore, is that adopted by Dr. Meadows. On this ground, then, menstrual derangement would be separable into amenorrhœa, dysmenorrhœa,

menorrhagia, and metrorrhagia, and the varieties depending on these forms; each requires to be considered in turn.

Amenorrhœa must be carefully distinguished from *delayed menstruation*, since, though in the latter class of cases; the menstrual discharge may not appear for many years; even after its usual time, yet it is a distinct condition, as will be seen later, from that of which absolute absence of all discharge at all times is the sign. The discharge usually appears for the first time at about 14½ years, but it is subject in this respect to almost infinite variety. In rare cases it is *never* established, and they called for particular and separate study. The diagnosis of amenorrhœa, however, is a comparatively easy matter. As its name implies, the presence of the condition is at once established by simple observation. The *cause* is another matter, and must be looked for in the condition of the organs implicated. Thus a mechanical obstacle may prevent the outlet of the discharge, in which case its progressive increase quickly reveals the true state of the case, for in every instance of true menstruation, *ovulation* is an invariable accompaniment, it is as invariably absent in every case of true amenorrhœa. Some inexplicable cases, however, must be admitted to occur; but in every instance of congenital defect, the subsequent unusual symptoms will be found due to the arrested development of the genital apparatus. Either the ovaries will have been arrested in growth, or the ovaries and uterus may both have shared in it; but, as a rule, there is a less degree of malformation than this, an imperfect kind of menstruation, small in amount, being possible to the organs. These cases admit of early recognition, and in them the ovaries can be proved to be the organs at fault. There are other cases in which the menstrual function, after being duly performed, perhaps for a considerable number of years, may become arrested and entirely cease, as a consequence of some local and general and constitutional changes, the essence of which Dr. Meadows' experience tends to demonstrate, is a blood-poisoning of some description. Thus, after blood-poisoning due to scarlet fever, arrest of the menstrua is by no means uncommon; and similarly, though less frequently, the same effect may be produced after measles, typhoid fever, and rheumatic fever. In all such

instances the pathology is obscure, but the changes are probably due to *atrophy* of the ovary, and no hope of effectually remedying the condition can be entertained. Colds taken during menstruation are another cause of arrested function. Pain is a frequent accompaniment of these cases, in which, inflammation being induced by the exposure, trophic changes follow, producing a state of things for which it is futile to expect a remedy to be found.

The cause of all the menstrual irregularities above described is arrest of *ovulation*; the ovary atrophies, shrivels, shrinks up, becomes mobile in the pelvis, but usually out of reach, and assumes a senile appearance. Diagnosis is confirmed by cessation of function, and the clinical history forms an explanation of the cause of the change.

Treatment of amenorrhœa, under whatever form, resolves itself into treatment of ovarian atrophy; and hence the indication first and foremost is, to stimulate the sluggish action of the organ. Very few remedies, however, can be relied on to effect this result—if, indeed, any—and when the condition is consequent on blood poisoning, absolutely *nothing* will avail to produce any benefit. Tincture of cantharides in ten to twenty minim doses have been most efficacious in Dr. Meadows' hands, where remedies have not been resorted to in vain; and rue and savin have a reputation in the same connection. Iron will be of service when the constitutional state demands it, and blisters may be productive of some slight good. The most efficient agent, however, in any case of the kind, is undoubtedly *electricity*, and the method of applying it as a stimulant to ovarian activity has occupied the attention of several authorities. The late Sir James Simpson advocated the use of an intra-uterine galvanic stem, by the employment of which the uterus is excited, lumbar pains are produced, and a slight discharge is provoked. This is certainly not a true menstrual discharge, since it possesses no ovarian character, and is not preceded by the excitement of ovarian activity to ovulation. Moreover, this mode of applying electricity is attended with serious risks, it being within Dr. Meadows' experience that it may be followed by retro-cellulitis and pelvic abscess, the stem in one case referred to having been removed with difficulty, and found to be covered with a thick membranous deposit from the irritated mucous membrane adjacent. Stimulation by galvanism for a short time daily has been adopted with better results, special bougies, sounds, &c., having been constructed to facilitate the passage of electrical currents to particular regions as required. Daily passage of sounds, introduction of sponge tents, and dry cupping, are other modes of promoting functional activity which are unscientific and extremely unsafe proceedings. By these means irritation of a kind is certainly set up, and a thin sanguineous discharge is provoked, but this is by no means *menstruation*, for, in the circumstances, the ovaries are not in the least degree affected, and without they are in active function ovulation and true menstruation cannot take place. It is nevertheless possible to transmit the electric current directly through the ovaries, several plans having been suggested for thus exciting them to action. The patient may be placed in a galvanic bath, or the poles of a battery may be adopted to secure the desired end in various ways. The bath is to be preferred in many cases, and in conjunction with it enemata of rue and tinct. cinnaomon on alternate days, for five or six times, may be advisable.

It is well to remember that obesity is a frequent accompaniment of amenorrhœa, and even plethora, the latter being more common in married women than in single. Also the uterus varies as the general condition of the body differs, and the general treatment must be carefully directed on well-known general principles, in regard to such conditions.

In *chlorosis*, amenorrhœa is not, as is very generally insisted, a *cause*, but a *consequence*, of the condition of the blood. To this is due the arrest of ovulation, and any

attempt to restore the function must be addressed to improving the state of the blood, without any regard whatever to the generative organs pending essential changes in the circulating medium. These once brought about, menstruation will be re-established without any special attention being directed to it. The digestive system, however, should be seen to.

Dysmenorrhœa in some of its forms presents characters analogous to those exhibited by amenorrhœa. It may vary wonderfully, from a large amount of discharge to a mere "show." As the amount of nervous excitation produced is to be taken as a measure of the ovarian act, it is evident that when this is scanty and abortive pain will not accompany it, the effect produced, or energy displayed, being too infinitesimal to bring it about. Nevertheless, as long as a discharge, however small in amount, is regular in appearance, there is good hope of restoring the functional vigour of the organ.

Scanty menstruation is commonly associated with obesity of figure, and sterility as a consequence of improper ovulation. Examination per vaginam of such cases shows that the organs generally are normal in form, &c., but that the ovaries are atrophic and, as a rule, undiscoversable by the fingers in this position. The uterus may exhibit scarcely any alteration. In all such instances the diminution and cessation of the menstrual discharge, are matters of time and degree, and are thus sharply separated from those in which total disappearance suddenly follows blood-poisoning. In case of gradual loss of function, emmenagogues may be found useful, but bromides and iodides are contraindicated when the signs are as above described. With them, however, electricity is signally serviceable, but must be frequently applied to secure benefit, the reason for this being that the remedy acts on a function which only recurs periodically, the ovaries and *not* the uterus being the organs implicated.

Entire *absence* of the generative organs is very rarely witnessed, only a single instance ever having come under Dr. Meadows' own observation. This was an infant which lived but a few minutes after birth: ovaries, uterus, and urinary organs were all wanting.

Rudimentary organs may be encountered. Thus, when the ovaries are abortively developed, menstruation will be very slight, and treatment must be directed to assisting the better development of the stunted organ. A rudimentary condition of other organs, e.g., uterus, vagina, and especially the mammae, usually goes with this condition of ovary when occurring congenitally.

The ovaries may be perfectly normal in all respects, and the uterus also, above the os, but from that point occluded. In such a case diagnosis will be simple if the vagina also is normal, for a globular, bulging tumour of increasing size will be found in the situation of the cervix, which needs only not to be confounded with pregnancy. The real nature of the case being understood a trocar may be introduced for the evacuation of the uterine cavity, care being taken to preserve the vaginal wall from contact with the confined, acrid secretions.

Lastly, dysmenorrhœa may be due to occlusion of the vagina, necessitating operative procedure for relief. Here it must be remembered that true amenorrhœa has not been present, and precautions must be taken to guard against danger to the patient, by (1) evacuating the collection of fluid slowly, (2) excluding air from admission to the pent-up fluid, (3) freely injecting disinfectants into the cavity opened; and (4) by acting on the uterus with oxytocics.

(To be continued.)

A MIDWIFE was, on the 30th ult., committed for trial for manslaughter by the Tunbridge Wells magistrates. She had, it was alleged, conveyed puerperal fever from one patient to another, and death resulted in the second case.

THE EARLY DETECTION AND TREATMENT OF DISEASE OF THE HIP-JOINT. (a)

By EDMUND OWEN, F.R.C.S.,

Surgeon to St. Mary's Hospital, and Senior-Assistant Surgeon to the Hospital for Sick Children, Great Ormond Street.

It is, I think, hardly necessary to insist at any length upon the importance of making a prompt estimate of the condition of an affected joint: it is in the early days that our treatment can effect so much; but if we allow the inflammation to get even a short start of our diagnosis, we may never be enabled to make up the lost ground. We may work at high therapeutic pressure, but we can never get abreast, as it were, of the adverse conditions. "A stern chase is a long chase." If it is necessary that we make an early diagnosis of the presence of joint-disease in children, it is only that the little patient may derive the utmost benefit from our treatment. That is self-evident. But, although the presence of some early, and therefore slight inflammation may be detected, still an unfortunate supineness in dealing with it is often to be deplored. And here I make a general accusation: the determined treatment of joint-disease is not, as a rule, undertaken sufficiently early. A child complains that his knee pains him; perhaps advice is obtained. The surgeon detects something amiss, and tells the mother, correctly enough, that the hip-joint is slightly inflamed; but when the mother asks what is to be done, he is apt to content himself with saying, "Keep the child quiet; do not let it run about very much." Instructions so indefinite are of little value. The child is allowed to run or hop about, and it is a matter of chance whether his trouble gets better or worse. In many children, I grant, the reparative powers are so active that even in these unfavourable circumstances the joint recovers; but there is a large proportion of subjects in whom a slight articular injury lights up so keen a local conflagration that in due course the synovial membrane, cartilage, ligaments, and even the joint surfaces of the bones themselves become consumed.

A strong, healthy-looking child is often the subject of rapidly advancing joint-disease. It would be an error to suppose that it is only in the so-called scrofulous child that a joint-trouble would become serious. I will, then, insist upon this that all children, with early joint-affection, must be treated alike; and in each case we must procure for the joint that absolute physiological rest of which so much has been written.

I must not open up the subject of treatment before we have dismissed that of diagnosis, but I will venture to say, in passing, that if the tender joint is in the lower extremity, the child must, for a time, be kept in bed: nothing short of this will satisfy the demands. It may seem to be a severe measure for so slight a matter, and in this light it strikes the mother, for she is almost certain to ask if it will not be equally efficient if the little fellow is kept on the sofa. No, it will not. The boy who is allowed to get upon the sofa will be off it upon the first opportunity. His book or his toy falls on to the floor; perhaps, even, it slides or rolls under the sofa, and he must get it. The affected joint is, with the others, pressed into the service, and, it may be, does its work so well that both the boy and his mother deem further confinement, not only unnecessary, but even prejudicial. At his next visit the surgeon finds the joint a little worse than when he left it.

Before I leave these prefatory remarks, I would suggest that the surgeon must never slightly regard a tender joint: he must rather give it his best and serious attention. He cannot tell of how much evil this is the starting point; and, to return to our own simile of the conflagration, I will ask what he would do if he found that some little flame was appearing between the

boards of the floor of one of his rooms. He would pour on water, nor would he desist until, not only flame, but smoke had ceased entirely to issue. Let us bear that in mind, his treatment would be equally energetic when only smoke attracted his attention. In the case of the joint, obscure pains or uneasiness in the movement are, if I may be allowed the expression, pathological smoke: acute symptoms are the flame which may or may not eventually burst forth. And the old adage is as full of meaning in surgery as it is in everyday life, "There is no smoke without fire." With us the child would agree that the inflamed joint is on fire; and neither has he, nor have we, wandered a hair's breadth from either the language or the thoughts of the old pathologists.

In order that we may examine a hip-joint in the early days of inflammatory changes, we will take the case of a boy who was pushed down the school steps three or four weeks previously. His mother heard of the fall, and two or three days afterwards noticed a bruise over the hip. It is now, as I have already suggested, about a month since the fall, and the boy complains of some stiffness and pain, perhaps, in the thigh or knee. I would not now allude to the fact of the pain in the thigh and knee being probably due to the distribution in those associated regions of certain filaments of the obturator nerve (whose anterior division also supplies the hip-joint), were it not that even now the knee is occasionally poulticed for disease of the superior articulation. As Sydney Smith, I think it was, said, "one might just as well have stroked the dome of St. Paul's to please the Dean and Chapter." When the child walks he limps, and is easily tired; and if the limb is handled roughly he shows evident signs of distress, so that I trust I may be pardoned if I ask that the limb may be examined with the utmost gentleness. Above all things, I would ask that the old fashioned plan of striking the heel or the great trochanter may not be resorted to. It is not only an unscientific method of investigation; it is rough and barbarous. It does not differentiate between disease of the hip and that of the sacro-iliac articulation.

The first step in the pathological process is effusion of thin synovial fluid into the interior of the injected synovial membrane. So the capsule becomes distended, and, bulging forwards beneath the muscles at the base of Scarpa's triangle, helps to obliterate the fold of the groin; and as it is only by comparison with the opposite side that one can estimate or make out this effacement it will be absolutely necessary that the child should have his trousers taken off before the examination is undertaken.

From this effusion the intra-articular pressure is increased and pain results, and the limb arranges itself in that position in which there is greatest roominess in the joint. This position is, briefly, that of flexion, the explanation being this,—that the anterior part of the capsule is, on account of the presence of the accessory band, much stronger than the posterior part, and refuses to yield sufficiently to give the extra room for the fluid which is increasing within the joint. But the back of the capsule bulges out around the neck of the femur until it can yield no more. Then increased space for the fluid is only to be obtained by flexion of the femur towards the abdomen.

To show that this change of position of the femur is exactly what might happen when inflammatory effusion fills the synovial membrane, I now inject fluid into the interior of a hip-joint by means of a small syringe which throws a stream of water through a perforation in the acetabulum which has been made from the pelvic side. Mark, as soon as I inject, the femur is flexed. This position of the limb is maintained as long as the joint is full; and bearing this fact in mind, the explanation of the rest of the anatomy of the earlier days of hip-joint disease becomes beautifully simple. Let us watch the

(a) Read before the Harveian Society of London, November 3, 1881.

boy (in our mind's eye) as he walks; he comes in carefully stepping on the tip of the toe of the affected side, and when he stands he leans over on to that side, and very likely rests his hand upon the front of his thigh.

First as regards the walk; the limping on the toe.

You will notice that in the diagram upon the wall I have represented in rough outline the bones of the right lower extremity in the normal, erect position. The hip and the knee-joints are straight, and the foot is firmly planted upon the ground.

In the next diagram you will see that the femur is slightly flexed as in the early days of hip-joint disease, and as we have shown in this injected joint. Now, because the knee is advanced, the extremity seems shortened, and the foot cannot reach the ground flat, as it did before. So the boy as he stands, can only get the toes to the ground, and as he walks he seems to paddle himself along with the tip of his boot. This method of progression is as characteristic of, as it is inseparable from, the condition of hip-joint effusion, but it does not differentiate hip-joint disease; any pathological state which involves a permanent flexion of the hip or knee will be characterised by this tip-toe symptom. So we shall find it in those cases of spinal disease in which abscess in the sheath of the psoas demands, on account of the pressure upon the cords of the lumbar plexus, an approximation between the thigh and the abdomen; and we shall find it also in cases of knee-joint disease, when the amount of the effusion within the articulation may almost be measured by the acuteness of the retiring angle of the knee-joint.

In proceeding to the differential diagnosis of these three conditions, the flexion of psoas abscess, of hip disease, and of knee disease, the subjective symptoms of pain will not be of material avail; for in each case persistent knee-pains may be the chief source of suffering. So the child must be put flat upon his back upon a firm mattress, and the knee must be gently flexed and gently extended; if its movements are free and do not elicit a complaint, or even an apprehensive facial expression, the trouble is not there. Then the thigh may be gently manipulated, and if its movements are free and painless, then we shall probably find that the head and front of the offending are in the lumbar vertebrae, and that the debris of the molecular disintegration and other products of inflammation are accumulating in the iliac fossa as an iliac or psoas abscess. But if the disease is at the hip-joint, after all, its presence will be best detected in the following way:—Bearing in mind that the flexion of the thigh is maintained in order that the pressure in the interior of the joint may be (diminished) that the pain is thereby reduced within its narrowest limits, we may infer that if we attempt to bring down the limb we shall increase the intra-articular pressure in proportion to the amount of tension which we impart to the anterior part of the capsule. And so it is. As soon as the attempt to bring down the thigh is made, every muscle towards the front of the joint, from the tensor fasciæ femoris on the outer side, to the adductor longus on the inner, springs into energetic contraction, and effectually prevents any straightening of the joint. Yet, if the manipulation be carried out with discreet but steady firmness, the thigh can, apparently, be brought down. This extension is but apparent, not real; it is the result of a tilting forward of the pelvis, and an arching of the loins, the relative position of the os innominatum and the femur being never once altered. To this arching of the loins, or extension of the pelvis upon the vertebral column, as a fallacy in the examination of hip-joint disease, I would direct especial attention; when the child is lying supine the amount of the deformity may even be estimated by the amount of loin-arching.

(To be continued.)

CASE OF DIFFUSED ANEURISM OF THE FEMORAL ARTERY TREATED BY ANTISEPTIC LIGATURE.

By T. H. MOORHEAD, M.A., M.D., Univ. Dub.
Medical Officer, Cooteshill Union Workhouse.

ON August 31st, 1881, I was asked to see Mr. K., a strong, healthy, looking man, æt. 30, who gave me the following account of his illness:—

Some weeks ago he observed a hard swelling on the inner aspect of the right thigh, just above the knee-joint. When first noticed it was about the size of a walnut, hard, painless, and pulsating. He showed it to a practitioner in the city where he resided, who told him it was rheumatism and prescribed a liniment. He thought no more about it till August 26th when he came down to the country and indulged in some violent exercise, jumping ditches, &c., after which he felt his leg rather stiff. Aug. 28th, while out walking, he suddenly got severe palpitation, with great pain in the thigh, and fainted. On his return home he found the thigh swollen, hard, and very painful. He had a soft sore and secondaries eight or nine years ago, for which he was treated with mercury, but of late he has been troubled with dyspnoea on exertion, and failing sight.

When I saw him he was up and dressed, his tongue was clean; pulse 80, temp. 99.4. The posterior aspect of right thigh was occupied by a large hard tumour, extending from the ham to the buttock, with extensive ecchymosis over middle third. He was unable to extend the leg which, together with the foot, was oedematous. A diffused pulsation could be felt over the lower half of the swelling, ceasing on compression of the femoral artery. A loud systolic bruit was audible over the same area and was propagated up the artery as far as Poupart's ligament. No pulse could be detected in dorsalis pedis artery.

Sept. 2nd.—I saw him in consultation with Mr. Young and Dr. Moore, and it was decided to make an attempt to treat the aneurism by compression, as the chances of ligature succeeding seemed small.

5th.—Cannot tolerate compression of the femoral, either digital or with a shot bag, for more than a minute or so at a time. Has been suffering great pain, relieved only by hypodermic injections of morphia; 3¼ inches above patella the circumference of the thigh is 19 inches, and that of opposite side 14½ inches. Pulse 100, temp. 99. A loud systolic murmur audible over aortic valve.

10th.—Has been getting rapidly worse. The circumference of thigh is now 20½ inches, and the surface of the aneurism is red and glazed. The pain for the last few days has been intolerable, and comparative ease has only been obtained by large doses of morphia hypodermically.

The nature of the case having been fully explained to the patient, and his consent obtained to amputation should the vessel on exposure prove unfit for ligature, I proceeded to tie the femoral artery at the apex of Scarpa's triangle, Dr. Moore administering chloroform, and Drs. Ryan and Sharpe assisting me.

The operation presented no difficulty. Strict Listerism was adopted; the vessel was tied with chromic acid catgut, and the edges of the wound brought together with sutures of the same material. Pulsation ceased in the tumour as soon as the ligature was tightened, and the dressings having been carefully applied, and the patient removed from the table to his bed, the limb was elevated and wrapped in cotton wool, and at 6 o'clock I left him quite comfortable.

At 8 p.m. I returned to see him. On looking at the dressings I found blood oozing from beneath them, and a considerable clot in the bed. As soon as the spray could be got to work I removed them, and found the wound distended with clot and a thin red stream issuing from the lower angle which pressure would not check. I re-applied the gauze and ran across the street to Dr.

Sharpe's residence, who was the only practitioner within four or five miles, but he had gone a long distance away to a midwifery case. Fortunately, I was able to get Mr. Armstrong, the local apothecary, who had most satisfactorily managed the spray for me at the operation, and with a stout-hearted neighbour to hold the candle and assist me generally, I again exposed the wound, cut the stitches, and turned out the mass of clot. So much were the sides of the incision infiltrated with blood that I could hardly reach the vessel as it lay at the bottom of the wound, but after some sponging I ascertained that the blood was coming from the distal side of the ligature and was only welling up slowly. I then compressed the artery at the spot whence the blood seemed to flow with my thumb and finger for a few minutes, and on removing them the hæmorrhage ceased. After waiting a little time to make sure, I brought the edges of the wound together with wire sutures and re-applied the dressings.

From this date his progress has been one of uninterrupted recovery. For the first few days the wound had to be dressed daily owing to the free oozing of serum, nevertheless it continued aseptic throughout, and united by first intention, except the upper and lower angles where blood clots slowly organised. The leg never lost warmth nor required artificial heat, and the œdema rapidly subsided. The temperature only reached 100 on one occasion—twenty-four hours after the operation—and on the ninth day was normal night and morning. For some days he complained of great pain in the foot and leg, but even this did not trouble him long, and was easily relieved by a hypodermic injection night and morning. On the 24th day I finally removed the gauze dressings, the wound being skinned over with the exception of one small spot, which soon healed under simple dressing.

On the 29th day he was out of bed, and a few days later got about on crutches. All the extravasated blood was by this time absorbed, the sac alone remaining, its contents still fluid, and measuring with the thigh $18\frac{1}{2}$ inches circumference. On the 30th day he got downstairs, and is now, eleven weeks after the operation, able to walk about with a high-heeled boot, the tumour being still a considerable size, but quite solid, and preventing the full extension of the leg. In all other respects his health is as good as ever it was.

There appear to be several points of interest in this case:—1st. The hæmorrhage which occurred a few hours after the operation (as I feared from the femoral artery) evidently proceeded from some small branch, which gave no trouble till it, together with the other branches, began to enlarge; 2nd. The effect of Listerism in saving the patient from a foul sloughy wound, such as would almost inevitably have resulted had it been treated in the ordinary way after its walls were infiltrated with blood clot, and 3rd, the effect of the diffusion of the aneurism. Our fear was that owing to the enormous mass of effused blood occupying the posterior and inner aspect of the thigh gangrene would have resulted, but it is now manifest that this mass of blood acted as a partial compressor of the vessel, and that the collateral circulation was fully established before the femoral was tied.

Clinical Records.

WESTMORLAND LOCK HOSPITAL.

Case of Gangrene.

Under the Care of RAWDON MACNAMARA, M.D.,
F.R.C.S.I., Senior Surgeon.

(Reported by MR. FRANK CAMPBELL.)

C. W., æt. 27, was admitted into the Westmorland Lock Hospital under the care of Mr. Macnamara, suffering from hypertrophied labia and chancres, which, after some little

time, began to improve under appropriate treatment, but these were soon followed by suppurating buboes on each side, the amount of pus discharged from these was excessive, and continued for a very long time, wearing the patient down very much. Mr. Macnamara having adopted a stimulating and energetic mode of treatment they healed up satisfactorily, and the patient began to improve in health and appearance. A month now elapsed during which she appeared convalescent, when huge abscesses formed on the buttocks, followed by extensive sloughings despite all Mr. Macnamara's efforts these remained open for nearly two months, when they finally cicatrised, only to be followed by an iliac abscess (left side) which opened first above, and afterwards below Poupart's ligament. The suppuration was very profuse and, notwithstanding that the patient was supported by stimulating medicines, and the best of diet, it wore her down to a skeleton. The left knee began to swell and contract, poroplastic splints were used to keep it straight; but the pain was intolerable, and despite all efforts the contraction continued and increased, until finally, gangrene which attacked the foot set in, and made rapid progress. The line of demarcation formed about four inches above the malleolus, and as a last resource Mr. Macnamara determined to amputate. The patient was at this time in a terribly emaciated state from the previous abscesses; she was put under the influence of the bichloride methylene. Mr. Macnamara operated by the circular flap, hands breadth below knee; very little blood was lost during the operation, as the arteries were well compressed. The stump was swabbed with a solution of chloride of zinc (40 grains to ounce) and the flaps brought together by silver wire. From this the patient made a steady and quick recovery. Her temperature never rose above 99° , and little or no pus escaped from the stump during cicatrisation. In three weeks it had entirely healed up. Two months after the operation she was attacked by a secondary papular eruption, which necessitated her continuance in hospital; this soon yielded to treatment, and in three weeks she was in perfect health.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, DECEMBER 9TH.

The President, JOSEPH LISTER, F.R.S., in the Chair.

TALIPES EQUINO-VARUS TREATED BY RESECTION OF A PORTION OF THE TARSAL BONES.

Mr. WILLIAM H. BENNETT exhibited a man, æt. 47, who had been the subject of the above description of talipes in a severe form. The patient had been born lame, and when an infant had been under surgical treatment; tenotomy had been performed with temporary relief only. For thirty-five years the patient had been walking much on the deformed limb, wearing an ordinary boot padded and adapted by himself. At times there had been most severe pains from the bursa which had developed, and the deformity had gradually increased. When admitted to St. George's Hospital under Mr. Bennett's care on June 25, 1881, the patient hobbled about in an unsightly manner. The left lower limb was wasted and shortened; the foot was much drawn up at the heel, and the sole was so twisted inwards that it was directed towards the median line of the body. The patient in walking or standing bore his weight entirely on the outer edge of the foot over which the skin was greatly thickened, and beneath this thickening bursa had formed. No alteration in the shape of the foot could be made by any force applied. On June 30th a portion of the central part of the tarsus was resected. A flap was turned back from the dorsal aspect of the mid-tarsal region, and with a chisel sufficient of the tarsus was chipped away, piece by piece, to allow the anterior part of the sole to be placed in a perfectly flat position. The tendo-achillis was divided, and the heel brought down as much as possible. The parts were accurately adapted, a drainage-tube introduced,

and the limb placed on a splint with a foot-piece. The operation was performed antiseptically and the wound dressed in the same way. The portions of bone removed included the cuboid and the scaphoid. No constitutional disturbance of any kind followed the operation. The dressings were changed for the first time eight days later, the wound had then healed excepting at its extremities where the drainage tube was lying. By July 8 the whole wound had soundly healed excepting a small sinus at the lower part. At this date antiseptic dressing was discontinued in consequence of irritation produced by the carbolic acid. A few days later erysipelas attacked the foot; cellulitis followed; the wound had to be opened up; all union between the bones, which before had been remarkably firm, broke down; and at one time much sloughing seemed likely to occur. By degrees this attack passed off, and after much trouble the foot was brought again into a good condition. By September 8 the wound had again healed, and the bones were again consolidating. The progress from that time was uninterrupted. On November 8 he was provided with a boot with iron supports and was allowed to walk. The condition of the foot when the patient was exhibited was described as follows:—The foot is somewhat shortened; the anterior part of the sole is as nearly as possible flat, and is planted firmly on the ground in standing and walking; the heel is still somewhat inverted, but can be made to touch the ground. The union at the point where the bones were resected is firm but not bony. The gait is altogether better than on the patient's admission into the hospital, and is gradually improving. Mr. Bennett thought the case might fairly be considered successful, and also that it demonstrated the desirability of performing this operation in certain examples of talipes. The case itself was peculiarly suitable for the form of treatment adopted, inasmuch as the long continuance of the deformity and the age of the patient rendered relief impossible by any milder procedure. It was suggested that fibrous union would be preferable to bony ankylosis as it would allow a certain amount of movement in a position where a joint is naturally provided. It was then submitted that the operation was one of extreme severity, and although performed with a successful result in a considerable number of cases recorded by other surgeons, should be resorted to only in those instances in which no other milder form of treatment could be adopted with success.

Mr. DAVEY expressed the satisfaction he felt at the general sanction which was being accorded to this class of operations. His own experience of them was limited to seventeen cases, and the success obtained justified him in anticipating that by-and-bye resection would be regarded as the only reliable treatment in all cases of the kind. He exhibited a foot taken from a post-mortem subject, and from which he had removed a wedge-shaped mass of bone, as would be effected in his mode of operating for excision of the transverse tarsal joint as a remedial measure for the malformation under discussion. This operation had been performed on a boy, *æt.* 10, who had been suffering from talipes equinus, and after remaining two months in hospital he could walk easily on the foot, which thus had been transformed from a useless to a useful member. The operation had been simplified as compared with its original form. A quadrilateral fold of skin should be removed from the outer side of the foot, and a special wedge-shaped director employed as a guide to the knife in making the subsequent incisions prior to removal of the bony mass, the form of which followed that of the director. All the seventeen operations had been performed with no other antiseptic precautions than a scrupulous cleanliness, and but one death had occurred out of the number. Mr. Bennett's case was undoubtedly the oldest patient yet operated on, but it should be recollected that children who are submitted to surgical interference for remedying the defect of club-feet, had been for years subject to interference of one kind or another; and in their case a radical procedure of even so serious a description might be expected to produce good results. In fact, the operation was preëminently beneficial, substituting a strong useful limb for a weak, useless, and malformed one, and the risk attending it might be estimated by the fact that no relapse had occurred in any of his cases, and only one death. He thought fibrous union between the bones might produce a valuable extremity.

Mr. HOWARD MARSH, admitting that talipes was a difficult subject to understand thoroughly, thought it would conduce to a better comprehension of the claims of the operation if an opportunity were afforded for examining the

cases described by Mr. Davey, and watching their future progress. Mr. Bennett's case was certainly so far successful, but it ought to be noted in the future. The operation was undoubtedly a dangerous one, and it ought to be had recourse to only as a final measure of affording relief. It seemed to him that Mr. Bennett's proceeding almost necessitated the formation of what might be termed a "wooden" foot, a consequence of the treatment pursued, since this involved the severance of the anterior and hinder portion of the foot so far as articular connection was concerned. A committee might, perhaps, he thought, be appointed to watch and examine the progress of the cases described.

Mr. HAWARD said no one who had seen Mr. Bennett's patient when exhibited at the preceding meeting of the Society, could doubt the successful issue of the operation. This, however, by reason of its severity, should be adopted with the utmost caution. He believed that the usefulness of such recovered limbs might even increase with time, and concurred in the opinion that their progress should be observed. In the case of children, it would rarely happen that a simpler and less dangerous operation could not be more wisely undertaken for the cure of these deformities, and it should be remembered that the previous treatment they had endured might favour relapse, this treatment, as a rule, being only half carried out from the ignorance, or impatience, or misplaced kindness of persons in charge of the patients; for instance, it not rarely occurred that the tendons were divided, foot put into position, and directions given for maintaining it so; and there all treatment ended, the limb returning to its malformed state owing to unwillingness of the parents to continue painful applications of apparatus, &c. If rightly and persistently followed, such treatment would rarely prove ineffectual. The few cases of talipes found in persons of advanced years might be proper subjects for the proposed operation, but it would be a matter for regret if, on this account, enthusiastic surgeons should be led away to its adoption with children.

The PRESIDENT thought there could be no doubt that, in this particular instance, Mr. Bennett had performed an operation which was indicated by the circumstances, and which resulted very satisfactorily. For children, however, it was inappropriate and uncalled for. Patient treatment of such cases would effect wonderful improvement, and by simple, unheroic measures. He was interested to learn the good results obtained by Mr. Davey without the employment of antiseptic precautions; but he considered that had he adopted them, instead of experiencing any surprise at the favourable consequences, he would rather have been astonished had they not ensued as a matter of course. Mr. Bennett would have done well to substitute eucalyptus oil gauze for the carbolic dressing when he discovered the injury done to his patient by the antiseptic, thereby avoiding any necessity for remitting the precautions against the introduction of septic influences. Erysipelas had been of very rare occurrence in cases treated antiseptically; only one instance had come under his notice in King's College Hospital. He had seen four cases where septic conditions existed which could not be removed, notwithstanding this treatment. They were, however, of a nature to indicate the difficulty of meeting the conditions surrounding them. One was a case of epithelioma of the vulva, and was necessarily out of the sphere of cases in which antiseptics could hopefully be pursued. He would, however, perform such an operation as Mr. Bennett described without any feeling of risk being incurred, pursuing it, of course, antiseptically. In the case of children, however, he should look upon such a proceeding as unnecessary mutilation.

Mr. BENNETT, in reply, said he had never met a single case of a child in which it would, in his estimation, have been justifiable to perform the operation; but in adults the conditions were different. When, in his case, carbolic irritation set in, strict antiseptic treatment was for a time discontinued, and this, doubtless, accounted for the attack of erysipelas. He expressed a doubt whether Mr. Davey would have had to chronicle the single death he mentioned in his series of cases if these had been treated antiseptically. That gentleman's mode of operating was, in every respect, admirable. He thought the progress of all cases of this kind, after operation, should be carefully watched.

Mr. JOHN R. LUNN on

TWO CASES OF MYXŒDEMA, MALE AND FEMALE.

First Case.—Male; family history, good. G. M., *æt.* 47,

a stout man, well nourished, movements of locomotion slow, skin dry, harsh, and translucent, does not pit on pressure. Whole of face puffy, especially under lips, suggesting renal disease; several moles on face, nose flattened, lips thickened, teeth fairly good, breath offensive, articulation slow, with a nasal intonation, hair on head thin, especially on vertex, thin on pubes, none in axilla. No apparent disease of fundus with the ophthalmoscope, fulness about supra-clavicular regions. Thyroid gland not to be felt, drowsy at times, does not perspire, temperature 96° — 97.2° , both sides alike, pulse small and weak 80, respiration 18, no anaesthesia or hyperaesthesia, taste good, no apparent chest symptoms, appetite good, *urine* sp. g. 1815, contains a trace of albumen at times, no sugar, no apparent increase of urea, with nitric acid. Has had delusions lately, and only passing 34—38 ounces daily, averaging 5.72 grains per ounce of urea, equal to 194.48 per cent. grains in the 24 hours.

Second Case.—Female; Mrs. J., *et.* 45, mother of eight children, four of whom are dead, cause unknown. She had had five miscarriages. No history of syphilis, gout, intemperance or fright. The woman has the appearance of a cretin, being drowsy, movements slow, hands look puffy, harsh and dry, never perspires, *ae* nasi thickened, always feels cold, temperature 97.4° — 95° , pulse 76 slow, R. 18, taste good, hair dark and thin, no thyroid gland to be felt, hearing not good, appetite fairly good, slight hyperaesthesia of whole body when pricked with a pin, slight bronchitic signs in chest, latter otherwise normal. *Uterus*, soft, axis normal, no disease. Catamenia stopped 1880. *Urine*, amber coloured, sp. g. 1020, vesical epithelium, distinct trace of albumen at times, no sugar, urea diminished in the 24 hours, 6.78 grains in each ounce. Often has horrid dreams, but no distinct delusions.

Dr. JOHN CAVAYT, on

TWO CASES OF MYXOEDEMA.

Case 1.—Was a woman, *et.* 59, married, who had had six healthy children and four miscarriages. The catamenia ceased at the age of 45. She had good health until eight years ago, when she suffered from dyspeptic attacks, which have come on at intervals ever since. Five years ago she was subjected to a severe mental shock, after which she gradually became very weak and low-spirited, walking with difficulty, and the characteristic swelling of the disease slowly supervened, but was not sufficiently marked to attract attention until two years ago. On admission there was moderate tense swelling of the cheeks, nose, and lips, with a bright patch of dilated capillaries on the cheeks, the skin of the face being waxy. The hair was scanty, the eyebrows raised and scanty, and the eyelashes largely wanting. The hands were rather broad and swollen, covered with dull reddish, dry and rough skin. The rest of the skin was dry and harsh. Her expression was dull and listless, and speech slow and nasal. The gait awkward and slow, common sensation blunted, special sense unaffected, and intelligence good. The thoracic and abdominal viscera were normal and the urine free from albumen. She was very chilly and her temperature was always subnormal, averaging 96.5° . The pulse was very slow, about 43, and urine scanty. She had two sudden attacks of dyspepsia and diarrhoea during her stay in the hospital, lasting a week and three days respectively, and was discharged feeling rather stronger, but with no appreciable change in her condition.

Case 2.—A married woman, *et.* 33, she had had five children in eleven years, of whom two survive and are healthy, the remaining three having died in infancy during teething. Five years ago after the birth of one of her children, she began to feel very weak, and at the same time her eyelids were swollen. In the course of a year the swelling became general, and her speech slow, with great awkwardness in all movements, so that she fell occasionally. On admission the face was much swollen, the upper eyelids especially pearly and semi-transparent, the nose very broad and the lips much thickened. The hands were large, clammy, red, and rough; the feet and ankles swollen, and the whole skin very dry and rough. She had a placid expression and slow speech, but intelligence and special senses were unaffected. Her movements were slow and awkward, common sensation rather dull, and she felt constantly chilly. Heart, lungs, and abdominal organs were normal, and there was no albumen in the urine. The pulse was constantly slow, varying from 45 to 65 and the temperature averaged 97.6° . She remained in the hospital nearly a month without alteration, and has since been an

out-patient. She has lately felt worse owing to grief from the death of one of her children from bronchitis, and the eyelids are more swollen, but there is no other change. It seems probable that the oedema and nervous symptoms are both due to a common cause in the central nervous system, as the former predominated in the second case and the latter in the first case. This view is supported by the slow pulse and sub-normal temperature, which was highest in the second case in which there was most oedema. The acute dyspeptic attacks in the first case somewhat resembled the gastric crises of locomotor ataxia.

Dr. ORD read notes of another case of the same kind.

Dr. MAHOMED wished to draw attention to certain points in these cases, which assimilated them in character to those of renal dropsy. He had collected together for the Guy's Hospital Reports a number of examples of this kind, and dwelt on the concurrence of evidence pointing to the existence of similar conditions in the two classes of disease, and especially the non-albuminous nature of the urine. He had regarded these cases, one having been recorded as an example of myxoedema by Dr. Goodhart, as instances of chronic Bright's disease without albuminuria, under which term he would also include Gull and Sutton's cases of arterio-capillary fibrosis. The result of his own experience and comparison of published cases had been to compel him to regard myxoedema as having much in common with such forms of Bright's disease; and even the changes in the spinal cord favoured this view, the nervous changes not being, moreover, an invariable accompaniment of myxoedema. On all grounds, therefore, and particularly on those afforded by the variability of albuminuria in both myxoedema and in the forms of Bright's disease he referred to, he thought that the explanations afforded of the myxoedematous state should be carefully reconsidered.

Dr. STEPHEN MAORENZIE moved the adjournment of the debate, and the motion was carried.

SURGICAL SOCIETY OF IRELAND.

THE First Meeting of the Session for 1881-2 was held on Friday evening, November 25, in the Albert Hall, Royal College of Surgeons.

Dr. CHAPLIN, President of the College, in the Chair.

Mr. TUFNELL, Hon. Sec., read the minutes of the previous meeting, which were confirmed.

The PRESIDENT delivered the Inaugural Address, the first portion of which we published in our last.

From time to time since the Contagious Diseases Acts, 1864 to 1869, came into operation at the Curragh, very many of my medical friends knowing the position which I occupied as visiting surgeon of the district, and medical officer of the Lock Hospital established at Kildare, have been inquiring as to the working of these Acts in that locality. I, therefore, think it may not be amiss on an occasion like this to offer some observations as regards the sanitary and moral effects of their operation. I am aware that you have had already before you an able and exhaustive paper by Mr. Thomson, in which he referred to the working of those Acts generally. I wish, therefore, to confine my observations nearly altogether to their operation at the Curragh district. It will not be necessary for me to notice the Act of 1864, further than to say that by it districts were apportioned, hospitals established, and inspectors, medical officers, and other officials were provided for them. Its provisions were altered and extended by the Acts of 1866 to 1869, under which the measures for the prevention of contagious diseases have been, and are being, carried out. The Act of 1866 extended that of 1864 in many ways. The Act of 1864 provided that a common woman, on cause being shown that she was a prostitute, and had a contagious disease, should be sent to hospital, examined, and, if necessary, detained. The Act 1866 extended these powers, and, for the first time, provided for the periodical examination of those women. It authorised the appointment of a visiting surgeon to examine them, and extended the period of detention in hospital to six months. This Act also provided that those women, on being discharged from hospital, should be sent home free of charge, and that on ceasing to be common prostitutes they may be relieved from examination. It also provides against the harbouring of common prostitutes affected with contagious disease in houses or lodgings. The Act of 1868 is merely explanatory with regard to the meaning of certain terms in the last mentioned Act, and the Act of 1869

extends the powers given in the Act of 1866 as regards the power of V.S., the extent of district, and the period of detention in hospital to nine months. It also extends the power of granting relief from periodical examinations by a justice, as in the Act of 1866 to the visiting surgeon, unless the woman is detained in hospital at the time. A few remarks will explain the working of these Acts. There must be a district, and in it a certified hospital, *i.e.*, certified by the medical inspector as to its fitness, &c. It must be provided with a medical officer, whose duties are confined to the treatment of the patients therein; chaplains, a matron. Outside the hospital, there must be a visiting surgeon, whose office is restricted to the examination of those women brought to him by the police. And there must be a sufficient staff of the latter to carry out the necessary duty.

The police at the Curragh consist of a constable and three sub-constables belonging to the R.I.C. (in England the metropolitan police). They are all married men, and have been specially selected for this position on account of their good character and fitness for the duty. They are under the immediate order of the sub-inspector of the district, without whose direction no compulsory measure can be initiated or carried out. The constable keeps a list of all the prostitutes in the district, and it is his duty to see that they come up at stated periods for examination, the times and place for which have been notified to the clerk of the peace for the county. Any woman being a prostitute is required to come and be examined at such times as the visiting surgeon may determine. *She may come voluntarily*, in which case she signs a paper (Form H) after the constable has explained to her the effects of it upon her, *viz.*, that she must so long, and only so long as she resides in the district, and is a common prostitute, appear periodically for examination; but if she does not avail herself of coming voluntarily, the constable then, after he has ascertained beyond doubt that she is a common prostitute, makes an information stating the circumstances of the case, and that she resides within the district, or being resident within ten miles of the limit of the district, or having no place of abode, has, within fourteen days, been within those limits for the purpose of prostitution, or outside those limits, has been in the company of men resident within the limits. A copy of this information, together with a notice (Form F) he gives to the woman, who is bound to appear herself or by any person appointed by her, before a justice, to answer what is stated in the information. Should she carry out the notice, she can claim to have the matter tried privately, she may even then voluntarily submit to examination, but if she fails to attend, or to refute the charges made against her in the information, the justice, on being satisfied, may order her to be subject to periodical examination, and may cause to be issued to her the order so subjecting her. On coming before the visiting surgeon he, previously to examining her, is bound to inform himself thoroughly (no matter whether she comes of her own accord, or is ordered to appear by a magistrate), of the circumstances of each case, and her knowledge of the effects of that which she may have done will have upon her. It is his duty also to tell her that she can, by good conduct, be released from the necessity of appearing at the examinations, and that if she wishes to be reclaimed, she will be aided in doing so. The effect of the voluntary submission, or the order of the magistrate, is binding for a year should she not be sent to hospital for treatment, or, having been sent there, till she is discharged. After having been so discharged, she is free from further subjection. The visiting surgeon is bound to have a notice (Form I), served on each woman as to times and place for examination, and if on examination she is found diseased, he fills up three copies by which she is admitted to hospital. One of these is given to her, another is forwarded to the hospital authorities, and a third is kept by the police. Should any woman from natural causes be unfit to be examined, if he believes that she is affected with contagious disease, he fills the Form L, by which she can be detained in hospital until she is fit to be examined, but not for more than five days; if drunk he can, under similar circumstances, have her detained in a bridewell.

When admitted to hospital she comes under the care of its medical officer, and may be detained there till cured, or for nine months. On being discharged he fills up a Form P, certifying to the fact; *this is retained by the police*. Should the woman have remained in hospital over nine months, and be not cured, or in case of her becoming affected with a zymotic disease, lunacy, or being advanced in pregnancy, he may give her a certificate (Form R) to the effect that she is

still affected with a contagious disease, and discharge her. This renders her liable to punishment if, after having been discharged, she is found pursuing her calling in any place. Whilst in hospital she can make herself acquainted with the regulations, a copy of which is hung in each ward. The 19th Clause of these informs her that *any patient, who sincerely desires to reform*, will, on stating her wish, be assisted as far as possible on entering a refuge, joining her relations or friends, or procuring employment on discharge from hospital. She is also informed that any patient who considers herself entitled to be discharged from hospital, may, if the medical officer refuses to discharge her, claim to be brought before a magistrate in order to have it decided whether she is fit to be discharged. Such is the manner by which these Acts are carried out, not only at the Curragh, but in all the other districts.

I now will bring before you the effects of the working of these Acts at the Curragh. As sanitary agents I have selected two years before the Acts came into operation, two years immediately after the Hospital was opened, and the years 1878 and 1879 because they afford a fair contrast as regards statistics. I would have preferred to have taken 1879 and 1880 for the last period, but the Army Medical Hospital Reports for the last year is not yet published.

There were on the police rolls of common women in 1870, 101; 1871, 104; 1878, 88; and 1879, 76. Many of those had been living on the Curragh from the time when the camp was established. Others came from different parts of England, Scotland, and this country (particularly Dublin). From Dublin there came in 1870, 15; 1871, 19; 1878, 16; 1879, 19, and had accompanied regiments there. As soon as the Hospital was opened, December 6th, 1869, those women were at once brought under the operation of the Acts, and those found diseased were admitted into it. In giving the admissions it is not to be supposed that each admission represents a different woman, for many of those were admitted twice and oftener in the same year. I have classified the form of disease for which they were admitted, according to the arrangement prepared for those Hospitals.

Return showing the Number of Cases of Venereal Disease admitted into the Kildare Lock Hospital during the following years:—

Total	205	217	240	208	870

Some of the worst cases admitted came from Dublin, or other places outside the district. They were cases of bad primary and secondary syphilis, condylomata, mucous patches and warts, the latter being accompanied with filthy and profuse discharge; *they were such that if not immediately admitted to Hospital would inflict fearful harm*. Nearly all the women admitted with syphilis presented the soft form of chancre, with enlarged inguinal glands, but very seldom accompanied with suppurating buboes; indeed, I don't recollect having seen more than six such since the hospital was opened. Secondary symptoms followed many of those sores, but I confess that I am not able to distinguish the sore that may be followed by secondary effects. Ulcers on the os, and within the canal of the cervix uteri, were not unfrequent, and were most troublesome to treat. I have not seen them except rarely on women, who have had no children, and I am inclined to think many of them secondary.

As to the effects of these Acts in promoting disease among the soldiers, I find on referring to the Reports of the Army

Medical Department, that it will be seen that the average per 1,000 of primary syphilis admitted to the Hospitals at the Curragh and Newbridge was (1868 and 1869, the Acts having been in operation 25 days in December of the last year) 85 and 88 respectively. In the two following years the average per 1,000 fell to 56 in 1870, and 35 in 1871. In these years the Order in Council stopping soldier's pay when admitted to Hospital with primary syphilis had not been promulgated, nor were the cases caught within the district separated from those introduced into it from without. Nor can I now correct the error, for the Police Reports for these years are imperfect. The Reports of the Army Medical Department gave the admissions for 1878 as 54, and in 1879, 77. These figures include all cases of admission to Hospital within the district, but on referring to the Police Reports furnished to me weekly, which contain the name, regiment, and all particulars connected with each case, I find that in 1878 the average per 1,000 was 28½, and in 1879, 36½, thus reducing the admissions in those years for primary syphilis caught within the district to in 1878 25½, and in 1879 40½ per 1,000. A careful scrutiny of the admissions for primary syphilis caught within and without the district by the different regiments shows that they generally bring disease with them from unprotected places; thus I find that in 1878 the 47th Regiment introduced in that way 24 cases, the 20th Hussars brought with them 34. The 47th remained at the Curragh for two years, and left it without having a single case in it; generally, disease diminishes in each regiment during its stay, unless where this diminution was interrupted by draughts coming from regiments stationed in other places, or men returning from furlough, and bringing infection along with them. I have not mentioned anything relative to gonorrhoea; I think the result would be equally satisfactory with it as with primary syphilis, for I find that in 1878 397 cases were admitted to Hospital, and in 1879 213. Many of these were relapses, and 184 in 1878, and 118 in 1879 were caught out of the district.

It will thus be seen that notwithstanding the introduction of disease by regiments coming from other stations, and from the women who have accompanied them, as well as those who come from various other places, the operation of the Acts at the Curragh has been beneficial. Placing statistics aside altogether, it must be apparent to all who wish candidly to inquire about the matter, that if a woman affected with disease comes into a district and is left to ply her calling undisturbed, she must distribute disease in proportion to the length of time she remains out of hospital. Many of such wretches and pitiable creatures have I seen since the hospital was opened; covered with filthy clothing, with broken down health, the result of drunkenness and debauchery, whose private parts were covered with mucous patches, the discharge from which was profuse and offensive. What must the result be to the man having communication with such? Ruin to himself, and probably to many others, the innocent sufferers from his sin.

When the hospital at Kildare was opened, the women who were admitted, "The Curragh Wrens," were found to be the most degraded of their class, living a wild life on the open common, exposed to the inclemency of the weather in all seasons, with no more shelter than that which the large breaks of furze, or a few rude huts, whose sides were formed of furze, and their roofs of corrugated iron—the refuse the camp could afford—sometimes living outside, other times, and in bad weather, within the huts. Crouched (for they could not stand upright) around a central fire formed of furze stubbings, they passed a life—to them attractive—of freedom, drunkenness, and debauchery, never visiting a house of worship, never receiving any spiritual care, few seeming to pity, few to care for them. They by degrees abandoned all civilised habits and ideas, and sank deeper and deeper in wretchedness and sin. Such was their condition, that when they were admitted to hospital they could hardly be induced to use the comforts provided for them. Many of them preferred to eat their meals at the fire, sitting upon their haunches, than to sit and partake of their food at the tables, or use the appliances with which they were supplied. It was, indeed, uphill work to make them change their ways. However, by kindness and forbearance on the part of the matron and the other officials of the hospital, they came to see that they were regarded with sympathy; by degrees they became civilised again. Most of them, except when under the influence of passion, ceased to use the vile language with

which they had been familiar; they became more tidy in their appearance and habits, and more amenable to discipline. For the first time for years they attended religious services, and had the advantages of religious administration. Although at first, in a half-rebellious, half-lazy mood, they assisted to do the work of the hospital, they, after some time, found that it was better for themselves to conform to its rules, as doing so materially contributed to their own comfort. By-and-bye they became, with but few exceptions, changed, and learned to [knit] stockings, make their clothes, and do the general work of the hospital. It is not to be supposed that all this was brought about without a great struggle for the mastery with some of them, but whenever insubordination arose it generally originated, not with the old *habitués* of the Curragh, but among the importations from Dublin and elsewhere. Even now it can be seen that where recourse to punishment is necessary for the repression of violence or breaches of discipline, it is caused by one or other of a few bad characters, who are thoroughly hardened in crime, and spend the most of their time in gaols. It is a pity that provision was not made in the Acts for the punishment of such characters in the hospitals, as in the workhouses, by solitary confinement and diminished diet, instead of sending them before magistrates, for in some cases the delay which occurs between the offence and its punishment takes a good deal from the effect of the latter. This might easily be arranged, and necessary safeguards provided that the *power* should not be abused.

Seeing the sad effects of disease and drunkenness on those whose health had given way, and witnessing the death of a few of their comrades, induced some of them to think of their own condition, and caused that change which led to their requesting to be sent to their friends, to reformatories, asylums, &c. On referring to the matron's report of these cases I find that 171 women were sent to their friends and parents, to reformatories, to hospitals, or died in hospital apparently penitent. Four of them were sent to America either at the charge of, or assisted by, the Secretary of State for War. One of them was a poor girl whose father was dead, and whose mother she had not seen since she was four years old. She was sent to America to her, and with the others who followed, were known to do well. It would detain you too long to go through the report, but it can be seen by it.

These Acts have been opposed on various grounds. 'Tis said they are immoral, and tend to increase vice by the supposed immunity they afford to its indulgence. That they have been useless, and that the good they are said to have effected has no foundation. That in carrying them out innocent women have been insulted, and that these periodical examinations tend to further debase those unfortunate women.

Those objections have again and again been refuted. Mr. Thomson, in the paper referred to by me, has done this so thoroughly that I will here only refer to some of them in which my experience tends to strengthen his refutation.

I think I have shown the operation of these Acts to have been physically and morally beneficial. I feel certain that in carrying them out *no innocent* woman has been insulted, or has in any way suffered by means of them. That the slightest complaint has not been made against the manner in which the constables perform their duty, or a whisper heard that they have abused their trust. On the contrary,

their operation has tended to diminish open solicitation, and prevent by their repressive action and the kindly warning conveyed to themselves or their relations, young girls—keeping bad company for the first time—continuing in that course, the end of which is destruction. Places where, before the Acts came into operation no decent female could pass through after dark without having her sense of delicacy offended, can now be traversed at all hours without such annoyance. As to the effect of the examination on these women, it will be seen by anyone taking the trouble to inquire, that their habits, dress, and manners have much improved since the Acts were introduced. With very few exceptions, they come freely to the examining room, and rarely indeed has (ten times in four years privateers) the constable in charge been obliged to resort to the penal clauses of the Acts to compel them to do so. The exceptions are those to whom I have before referred. They try to avoid attending, not that they feel themselves debased by doing so, but that they fear being sent to hospital, for, generally speaking, such are careless about cleanliness, and consequently more prone to disease.

Return of Women sent to Reformatories, Homes, Parents, Friends, and Unions from Lock Hospital, Kilaare, since 1870. Also Number of those who Died in Hospital.

I have certainly found occasionally some who pretend to be shy, and affect a mock modest manner. They are almost invariably diseased, and on admission to hospital are found to be, both in demeanour and language, no better than the rest. I recollect one such in particular. Her examination proved she had bad secondary disease, which she would insist she had got a few days before. Soon after her admission to hospital I found that she had made a charge against a soldier for having raped her and given her disease. Upon her information he was sent to gaol, but at the Assizes, on my informing the Crown solicitor of the above-mentioned facts, he entered a *nolle prosequi*. There was no doubt that whilst her husband was away on detachment duty she had gone loose, and reasonably suspecting that all was not right with herself, and in order to throw dust in her husband's eyes, made the false charge referred to.

I believe that without periodical examination these Acts would be useless. Some come voluntary to the hospital when disease prevents them from carrying on their trade; but I am confident that unless compelled, few would be found to seek admission there in the early stages of disease before they had contaminated others, and when their retirement there would have largely benefited themselves.

Gentlemen, I have to apologise for the length of this address, and to thank you for your kindness in listening to it. If I believed that the effects of disease resulting from the unhealthy illicit intercourse of the sexes could be confined to the persons who had originally transgressed, nothing would induce me to prevent the removal of these Acts from the Statute Book; but confident as I am that this is not so, I feel that it is our bounden duty to endeavour by all means at our disposal to check the ravages of a disease that is the greatest scourge that could afflict humanity; that stalks in secret throughout the length and breadth of the land, affecting not only the guilty, but the innocent and unborn, the peer and the peasant, and which destroys the health, blights the happiness, and involves in wretchedness and ruin its mi-erable victims.

Dr. Wheeler's paper on "Nerve Stretching for Tetanus," and the discussion thereon, will appear in our next.

The Mineral Waters of Europe.

THE "MEDICAL PRESS"

ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.
President of the Pharmaceutical Society of Ireland, Lecturer on Chemistry, Carmichael College of Medicine, &c.

WITH

NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P. Lond.
Lecturer on Materia Medica and Therapeutics at the London Hospital, Physician to the Hospital for Diseases of the Throat, &c.

(Continued from page 495.)

THERAPEUTICS OF TABLE WATERS.—(Continued).

Adelheidsquelle.—This is a much stronger water, containing nearly 29 grains of solids, as against 17½ in seltz-r. The strength is due almost entirely to the salines, which amount to nearly 24 grains. The antacids are rather less than seltzer, but the alkaline reaction is well-marked, being due chiefly to sodium carbonate. The purgatives are so slight that they may be practically disregarded. The presence of iodides and bromides make this a useful table water where those salts are indicated in combination with salines, or may lead to the selection of this where a saline water is wanted for a patient taking pharmaceutical preparations of iodine and bromine. It has some claim to be considered a medicinal as well as a dietetic water, and has considerable repute in glandular and cutaneous affections.

Gerolstein is a light, antacid, well aerated water,

grateful to both palate and stomach. The mineralisation is slight, and composed chiefly of antacids, these being nearly equally alkaline bicarbonates, and carbonates of the alkaline earths. Compared with seltzer it contains less total solids, but much more antacids, one half the quantity of purgatives, and scarcely any salines. It is then as a pure, digestive, mildly antacid, table water that Gerolstein must be employed. It mixes well with milk and may be taken freely as a beverage.

Bellthal.—Antacid, contains only eleven grains of solids in a pint, but the presence of nitric acid, ammonia and phosphates is objectionable.

Wilhelm's Quelle.—A light, saline, highly aerated, feebly antacid water, the last property being chiefly due to calcium carbonate. There is also a small quantity of iron and traces of bromides, and iodides. This water has obtained a high reputation, and, as it is pleasant and perfectly free from organic matter, deserves a trial.

Birresborn.—This is a more decidedly alkaline water, out of the twenty-one grains of salts in the half-pint no less than eighteen being antacid. With a grain of purgatives it may sometimes seem aperient, and in no case would constipate. It should suit well when seltzer is not sufficiently antacid.

Harrogate Kissingen may be used as a table water when chalybeates are indicated as well as a saline beverage. It may, however, be fairly classed as a medicinal water. It contains thirty-eight grains of solid matter in the half-pint, of which thirty-four are the salines, distributed after the manner of table waters. The same quantity also contains 1-3rd grain of iron, giving it a ferruginous character, and three grains of salts which may be sufficiently aperient to counteract the tendency of the iron to produce constipation. The water is artificially aerated and will therefore keep in bottle. This water is closely related to that of one or two springs at Kissingen in Bavaria.

Saint Galmier.—This has long been a favourite table water in France, and most people who have travelled in that country are acquainted with it; it has been called the French Seltzer water. It is a light digestive beverage, containing quite a number of ingredients, distributed in excellent proportions. Thus it furnishes a light, antacid drink, uncomplicated with much saline matter, only 1 gr. in the half pint, and with just enough aperients to prevent it from constipating. It may be mixed with other drinks without spoiling them, is somewhat aerated, and is perfectly pure. It is quite a typical table water.

Rosbach is aerated at the springs by the natural gas which escapes. It seems to be a saline water, feebly antacid, and without a trace of aperients.

Contrexéville is a light water, with $1\frac{1}{2}$ gr. in the half pint of antacids, and the same amount of salines, but these springs yield traces of arsenic and of iron. For a century and a quarter the value of the water has been asserted by medical authorities, and it is nearly as long since English invalids began to visit the village. The waters are in most repute for gout, and diseases of the bladder, and prostate. In most disorders of the urinary organs, a systematic course has been recommended. Civiale expressed a strong opinion as to their great utility, and there seems no question that they do determine to the urinary system. Durand-

Fardell (a) recommends Contrexéville in renal colic and in catarrh or inflammation of the kidneys when Vichy or other alkaline waters are contra-indicated. An attempt has been made to treat diabetes by this water, to which may be added, that it would be found a suitable water when arsenic is being taken as it contains a trace of that element.

Orezza is a valuable, highly sparkling, chalybeate water containing sufficient iron to give it a claim to a position as a medicinal article, though it may also be used as a beverage by patients who would be benefited by steel. In all anæmic cases it may, therefore, be used as a tonic table water.

Schwalheim is a sparkling, very slightly chalybeate water with some antacid properties and no tendency to constipate. It contains also some salines and is agreeable to take. The iron is in less quantity than in Orezza—as one-tenth to one-half.

Baden-Baden has lately made great efforts to increase the attractions of its springs, and Prof. Bunsen finds the waters contain arsenic. His elaborate investigation shows that the water is constant in its composition and the supply is unlimited. It contains 12 grs. of solids in the half-pint, the salines being $9\frac{1}{2}$, the antacids $\frac{1}{2}$, with a trace of purgatives and arsenic. This water sits well on the stomach and may be found an agreeable beverage when arsenical preparations are being taken or may be utilised as a menstruum for them.

Besides the foregoing, there are springs at Buxton, Bath, Malvern, and other English resorts from which waters are furnished, which may be taken at table, as indeed may the waters of many "Holy Wells" scattered over the country, and in more or less local repute. To this class may also be added the weaker saline waters in so much esteem on the Continent. The water of Purton Spa has been usually classed with purgatives, but the aperient property of some of its ingredients is almost entirely neutralised by others, and claims are made for it on account of its bromides and iodides. We have, however, employed this, and some others, as a table water after the manner spoken of in reference to those containing arsenic or iodides.

THE annual rates of mortality last week in the large towns of the United Kingdom per 1,000 of their population were, in—Edinburgh 15, Wolverhampton 15, Portsmouth 16, Birmingham 17, Bradford 18, Bristol 18, Oldham 18, Sheffield 19, Plymouth 19, Leicester 19, Newcastle-on-Tyne 19, London 19, Glasgow 19, Norwich 20, Salford 21, Leeds 21, Brighton 21, Nottingham 22, Dublin 24, Sunderland 24, Liverpool 24, Hull 26, and Manchester 26.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 33, Bombay 25, Paris 24, Geneva 25, Amsterdam 22, Rotterdam 23, The Hague 23, Copenhagen 27, Stockholm 15, Christiania 18, St. Petersburg 43, Berlin 25, Hamburg 24, Dresden 21, Breslau 24, Munich 24, Vienna 27, Prague 29, Buda-Pesth 29, Naples 28, Venice 26, Alexandria 35, New York 29, Brooklyn 23, Philadelphia 21, and Baltimore 25. No returns were received from Madras, Rome, and Lisbon.

THE
MEDICAL PRESS AND CIRCULAR

Is published every Wednesday morning. Price 5d. Post free, 8½d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6

" IF PAID IN ADVANCE 1 1 0

* Post-office Orders and Cheques to be drawn in favour of—

A. A. TINDALL, 20 King William Street, Strand, London, W.C.

A. H. JACOB, 3 Molesworth Street, Dublin.

Agents for Scotland:—

MACLAUGHLAN and STEWART, South Bridge, Edinburgh.

A. and W. STENHOUSE, Hillhead, Glasgow.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Philadelphia, by Dr. BRISTON, post free in advance, 5½ dollars (£1 2s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order

ADVERTISEMENT SCALE.—Whole Page, £5 0s. 0d. Half Page £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth Page, 12s. 6d.

Small Announcements of Practices, Assistancies, Vacancies, Books, &c., of Seven lines or under, 4s. per insertion; 6d. per line beyond.

Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

WEDNESDAY, DECEMBER 14, 1881.

TRAPS FOR FOOLS.

It is impossible now to take up any ordinary newspaper or other publication addressed to the general public, without finding in it instance after instance of the mischievous ingenuity with which traps for the foolish are set by unprincipled advertisers of worthless nostrums. Nor is it by any means only the lower class papers and serials that exhibit too great willingness to accept the highly charged but questionable announcements; even the organs of public opinion which arrogate to themselves the title of “leading” daily or other papers, sink themselves in this direction to the level of the meanest and most contemptible “penny dreadful.” Indeed, a careful examination of the contents of the principal dailies, extending over a period of many months, reveals such wholesale advertising, not merely of quack remedies, but also of an equally harmful, though more insidiously injurious class of nostrums, as suggests a startling conclusion regarding the danger thus temptingly put before the public. Thus, dentrifices, solid, liquid, and of every other kind, warranted to beautify, cleanse, and even restore the teeth,

however neglected or decayed; hair washes, hair dyes, and hair tonics, possessing powers undreamed of by the most ardent specialist in dermatology; pills, whose multiple qualities adapt them equally for the cure of cancer, piles, or bronchitis; balms, balsams and creams, application of which is warranted to insure complexion of ravishing hue; these, and a myriad of like impossible remedies, are each day found in newspapers, placed at the foot of a column, and set in that particular type and style which unerringly indicated the special rate charged for their insertion. In addition to these, in themselves of sufficient evil, we have to draw attention to yet one other form of announcement, which it is nothing less than disgraceful to the conductors of a respectable journal to accept for publication. This is that particular description of notice which, in the most unblushing way, invites invalids to consult the proprietors of quack institutions, respecting the ailments they suffer from. Some years ago righteous indignation was excited against harpies who ruin the health and prospects of those deluded beings who apply to them in response to oily invitations to consultation “in all cases of a private nature.” The consequence of the outburst of wrath then excited, was rigid exclusion of all such advertisements from the pages of respectable papers; but we find now that in a lesser degree, but with no less offensive results, equally disgraceful, and equally illegitimate announcements find daily admission to the press. In proof we have only to quote the advertisement of “a golden medical discovery” said to be specific in almost every disease, and possessing all the virtues usually assigned to secret remedies, accompanied by a request for the public to consult the gifted author of this marvellous heal-all; or we may call attention to a freely advertised institution, the advantages of which are offered to women, and the unqualified proprietor of which, also a benefactor of unknown proportions from the evidence of his handbills, magnanimously sells his opinion for one shilling on each case submitted to him. All these surely point but too truly to the gradual introduction of a laxity which may result by and bye in a scandal as grave as that which was vigorously suppressed a few years ago. It is no palliation of their crimes that the eminent lights of American medicine who flood this country, with preparations vaunted as infallible in every disease that afflicts unfortunate man, shield themselves from actual prosecution for unqualified practice by employing some out-at-elbows and elastic-conscienced possessor of a British diploma to act in such cases as may, without this precaution, terminate in difficulties. Our laws, however, with regard to the practice of quacks is so very tolerant and unexact, that, unless he acts with an utter disregard to caution—which these gentry rarely display—any would-be offender against it can pretty safely speculate on escape from the few meshes it spreads. Thus it is that so many traps of the kind are set in so many different situations; and thus it is, too, that the miserable pretenders who set them are able to pursue a system of plunder and maltreatment up to the last moment at which it can be done with safety to themselves. Robbed of health, money, and time, the wretched victim then

comes to the charitable institution which should have been resorted to in the first instance, whenever the fee of a legitimate practitioner is beyond his means; and then commences a tedious system of treatment, which, but for the disgraceful proceedings the patient had been subjected to, would never have been necessary at all. Hundreds of such instances come weekly before hospital officials, and the number of them is chiefly maintained by means of the advertisements contained in the daily papers.

Again, the number of special notices addressed to women particularly, is becoming larger and larger, as each addition to the series is seen to provoke remunerative response. For it is one of the most astonishing features of these advertisements that, costly as they are, from the premium put on them by newspaper proprietors, they nevertheless appear not for once or twice, or occasionally only, but day after day, and month after month, thus demonstrating the enormous sums obtained from the numbers who are daily deluded by them. We recently counted in a single number of a penny weekly publication, which we are assured is read entirely by women, and which has a very extensive circulation among the ignorant and ill-educated classes, no less than *thirteen* different advertisements of preparations for restoring the lost beauty of skin or hair. Were it not that we know what disastrous consequences follow the employment of these baleful concoctions, it would be amusing to read the preposterous statements made about them. Thus one enterprising advertiser asks, and no doubt obtains, *ten shillings and sixpence* for a pot of stuff which "removes small-pox marks, cicatrices, birth-marks, moles, wrinkles, &c., and ensures a new skin." This delectable composition is then described as "perfectly harmless," and but for the certainty one must experience that the whole thing is a swindle of the first order, it might be interesting to learn what "quite harmless" substance would be equal to eradicating a cicatrice and creating a new skin. This is but a single sample of the announcements we refer to, but it illustrates their character with sufficient clearness. It must be said again that the journal whence the abstract is taken is little read, save by uneducated women and hysterically-minded domestics; but these, unfortunately, are just the class likely to be influenced by the nonsensical descriptions of nostrum mongers. In their case such advertisements are most excellent traps for fools; and most excellently, judging from experience gained in out-patient departments of hospitals, do they act. The number of skin affections set up or encouraged by the advertised "beautifiers," is beyond all calculation, and we cannot but think the time has arrived when respectable papers should place restrictions on the dissemination of announcements productive of so much serious harm. Let them cease to advertise traps for fools.

PROFESSOR CHARTERIS ON THE GERM THEORY.

[COMMUNICATED.]

PROFESSOR CHARTERIS has issued, in a separate form, his thoughtful Introductory Address to the medical

students at the opening of the winter session at the University of Glasgow. We have had "thoughtful address," and we might add "well expressed address," while we differ entirely from him in many of the positions assumed, and the conclusions drawn from them. By everyone who knows anything of Dr. Charteris's writings on medical subjects, it will be readily admitted that if he is anything at all he is a thoroughly satisfied and hopeful exponent of medical science—a thorough believer in the power of drugs, and a ready acceptor of new ones. This may, and doubtless does, result from the groove in which his inclination, his studies, and his good fortune may have led him. We are sorry to confess that we do not see such cause for thankfulness in the past progress of medicine, nor are we equally hopeful of the future. We belong to that class of ancient people who worship at the shrine of the god Terminus; or who, as Dr. Charteris better puts it, "love to stand on the ancient pathways and swear by the Shibboleths which gladdened their hearts in their youthful days, but they represent only a body small in numbers and unimportant in influence." A small particle, however, Dr. Charteris should remember leavens a large lump; truth is, more frequently than the reverse, the possession of the few, and once a fact a fact for ever. No science can be worthy of the name whose particular truths once established, can ever be shaken. But there are two distinct kinds of success and satisfaction in life, the one based on piping to the fickle and ignorant multitude, the other on steadfast devotion to the eternal verities. Medical science, so-called, is charmed by periodical "fads," the public become possessed of them, and by the great majority of practitioners it is regarded as the best policy to join the universal chorus. Any one who philosophically contemplates a given period in the history of medicine need not be informed of this. With how many "infallible cures" have the pages of our journals groaned during the past ten years which are now consigned to the tomb of irrevocable forgetfulness. The present "fad" is what is called the spore-theory, and the great spore-killer and cure-all—carbolic acid. To this theory, and to this acid, numerous men of acknowledged ability have unquestionably bowed, and on it has been based a mode of treatment which threatened to revolutionise the former physiologico-chemical mode of treatment, one whose scientific and rational aspects found a successful exponent in a former possessor of the chair which Dr. Charteris presently holds, on the classic banks of the now subterranean Molendinar.

Dr. Charteris, we notice, at the onset of his address, accepts Pasteur's experiments as elucidating satisfactorily the nature and treatment of a very important class of diseases—viz., acute zymotic diseases. We pass over, without further remark than stating our disbelief in the assertion, that tubercle is an infectious disease communicable by man to the lower animals, and of being reproduced in the human subject by the drinking of the milk of tubercular cows! Even if it were thus an infectious disease why should it matter if tubercle can be cured by three grain-doses of the hypophosphite of lime or soda, or if the patient suffering from "galloping consumption" and tubercular peritonitis, can be rescued from the grave even, as it were, by "the skin of his teeth." Verily, we do live in startling times. If these statements be facts, they are

surely among the mightier achievements of the nineteenth century! When are we to receive confirmatory testimony from *men of science*? Compared with the dubiety which surrounded the nature of zymotic diseases in former times, Dr. Charteris indulges the following pœn: "We live now in a different time, and we have stripped off much of the mystery which surrounded their course. We say that they are dependent on particular lowly organisms, that these organisms, entering into the system, produce and reproduce themselves in numbers infinite, and possibly definite, in form. Their hostile inroad is marked by an unvarying period of incubation, and when this is completed they seem to awake to life. They then impair health, nullify animal vigour, and produce increased combustion and fever. Moreover, we can truly say, with reference to these organisms from which they originate, that like produces like, and that alone, and that a specific fever, the outcome of their multiplication on the human body, will retain its inherent characteristics, and never, however weakened the system, merge into another. Thus small-pox produces small-pox; scarlet fever, scarlet fever; typhus, typhus; and typhoid, typhoid;" and so on *ad astra*. This is the theory of the deservedly popular Professor of *Materia Medica* at the University of Glasgow. These wicked spores! Their conduct reminds one of the slumber, the rumbling, and final explosion of a Vesuvius or a Stromboli before it vomits its liquid death on the dreaming peasant of the plain below.

Applied to the elucidation of particular diseases, we are to believe that the germ of typhoid poison selects, as its manoeuvre ground, a certain part of the intestine; that of typhus seizes on the nervous system; that of scarlet fever on the throat; of diphtheria the same part, but permeating and implicating the whole glandular system; that of rheumatism, the joints; mingles the skin; whooping-cough, the recurrent laryngeal nerve, and so on, *ad infinitum*. This is surely drawing on the credulity of any educated person to an extent that homœopathy never dreamt of. Against the theory, if it can seriously be entitled to the dignity of such a name, it appears to us reasonable to urge, 1st, that the very existence of these germs has never been proved. Even Dr. Charteris himself admits "we cannot place them on the microscope slide and say, 'Lo! there's the germ, there's the embryo of the races' fatal enemies:'" and the Professor adds, with a complacency that is certainly not justifiable by fact, "But that they do exist no one attempts to deny, for it is the only logical conclusion to be drawn from the history of the maladies!" 2ndly, It may be urged against this precious theory, that it presupposes a peculiar germ for every different disease, and worse than all, their possession of a dreadful instinct for pouncing on the most vital part which plays havoc with the teleological argument of design—"That they do exist no one attempts to deny." Dr. John Dougall, who has devoted a good deal of intelligent attention to this subject, lecturing at the Royal Infirmary of Glasgow, exactly about the same time, remarks (see *Med. Press* Nov. 16, 23): "The chief points adduced by the germ-theorists in support of the malignant function of such minute organisms are—1st, That they are present in all putrid, and absent in all fresh or healthy organic matter. 2nd, That many diseases, both of animals

and plants, they allege, are caused by parasites and fungi. The *opponents of this theory, of whom I am one*, hold that all such organisms are the result of the morbid conditions of their *habitat*—1st, Because that, whether bacteria, parasites, or fungi, they are only found on the parts of animals or vegetables of lowered vitality, or in their dead tissues. 2nd, That by strengthening the vitality in living, or arresting decay in dead, parts, they disappear. 3rd, That when present in infectious matter it loses its power to infect, as observed in small-pox and vaccine virus. On these grounds the functions of such organisms are held as *beneficent*," Prof. Owen terming them "Nature's scavengers," for maintaining the salubrity of our atmosphere, and "Nature's Invisible Police" for arresting the fugitive organised particles and turning them back into the ascending stream of animal life. Now, is it really necessary to ask any intelligent man to which theory he will profess adherence! Alas! who can decide when professors disagree! One startling assertion of Dr. Charteris's we notice in conclusion: "It is possible, also, that against the germ which makes the name diphtheria a word of evil omen in every household, we have a newly-discovered drug—pilocarpine, an antidote as potent, as some confidently anticipate, and all eagerly desire." On what established observation is this based? The question is, Is pilocarpine an antidote against diphtheria in any degree whatever? Might it not be worth while that Dr. Charteris select a case of diphtheria and satisfactorily demonstrate this to, say six intelligent men in the profession in Scotland? As for the rheumatic spore, and its death by the salicylates, it must fall in the same fell swoop. We have tried the salicylates and found them inert! We are sorry to have been called upon thus to notice Dr. Charteris's address. For himself personally we have the highest regard; we only wish we could say the same for his theory.

Notes on Current Topics.

Scientific Garrotting.

A NEW danger has been created of a nature to arouse most uneasy feelings in the minds of those compelled to traverse alone the more unfrequented streets of large towns. This was exemplified in one of the metropolitan police-courts on Thursday last, when two persons, a man and his wife, were charged with robbery from the person, their victim having been first—in some unexplained manner—rendered unconscious by chloroform or ether. The circumstances under which the anæsthetic was administered were not described, the prosecutor knowing nothing further than that he found himself in a police-cell on the south side of the Thames at 3 o'clock in the morning, with no recollection of the events intervening between that time and 5 o'clock on the preceding afternoon, when he was proceeding homewards from the Euston Railway Station. In the interim he had been robbed of all valuables about him at the time. A strange fact in connection with the case is that relating to the theory by which the police accounted for the condition of the victim, whom they at once concluded to be drunk and incapable. It is, however, sufficiently startling that

such an occurrence could take place in London, in daylight almost and the ingenuity, and scientific knowledge displayed by the prisoners may well be regarded as a future terror of no mean proportion.

Anti-Vivisection Fanaticism.

We learn with pleasure that the movement to which we referred under this heading in our last, is making satisfactory progress, and that an Association for the protection of scientific workers from the persecutions to which they are liable in the present state of the law, is in process of rapid formation. From Mr. Darwin downwards, we believe the majority of eminent scientists have expressed their sympathy with the project, and have made offers of pecuniary and personal assistance. It only now remains to organise the moral and material force thus made available, and no doubt this will be done without delay. A meeting will be shortly called to appoint a committee and working officers, and this being accomplished, the Association will be able to set about its appointed task. Those desiring to co-operate in this excellent undertaking can, in the meantime, communicate with Dr. Lauder Brunton, F.R.S., 50 Welbeck Street, London.

The Vienna Tragedy.

VIENNA was, on Thursday last, the scene of a terrible tragedy, whereby more than 300 people lost their lives. The old story of carelessness, panic, and destruction was once more illustrated; a theatre packed with victims, declared to be on fire, and with no means of egress at all adequate to the need of the occasion; in terror of death the surging mass of human beings poured towards the few tiny outlets, only at once to block up every opening to the exterior. This ought to be another warning to Governments which still permit theatrical proprietors to build places utterly unfitted to the objects they are destined to serve; nor are we in England altogether free from a similar reproach.

M. Pasteur.

ON Thursday last the French Academy proceeded to the election of three new members to fill vacancies in their body recently created by death. One of the successful candidates is M. Pasteur, whose infinite claims on the gratitude of mankind are thus recognised by the bestowal of the highest honorary distinction possible to be obtained in France.

Galvano Puncture in Aneurism.

THE treatment of aneurism by galvano-puncture has frequently formed the subject of suggestive comments by speakers at society and other meetings during discussions on the method of proceeding for the relief of these tumours, but it has never yet received any considerable sanction from surgeons. In connection with it, however, the *New York Medical Record* for November 24 last, records a cure of aortic aneurism, which presents some points of interest. The case was under the care of Dr. Richard Cameron, of Valparaiso, Chili, the patient being a man forty years of age, and the tumour situated on the ascending arch of the aorta. The reme-

lies more commonly relied on having failed to produce any result, galvano-puncture was resorted to as a last resource. Two fine steel gilt needles were passed into the aneurism and retained in position for twenty minutes, and after about two weeks interval the swelling subsided, and the symptoms thenceforth slowly, but permanently disappeared. A curious fact, however, was discovered after the needles were removed, namely, that owing to defective action of the battery no current had practically been passing during the operation, and thus is opened up a field for speculation concerning the means whereby the beneficial consequences were brought around. It is perhaps allowable to presume that the previous treatment had something to do with the result, and that the irritation set up by the mere presence of the needles completed a reparative process which needed only some such stimulation to effect the ultimate end gained. In any case, however, the history is a very instructive one.

The Radical Cure of Cancer.

PRIZES to the value of three hundred dollars, and one hundred dollars for essays on "The probability of the discovery of a radical cure of malignant disease, and the line of study, or experimentation most likely to bring such a cure to light," are offered by advertisement in the *American medical journals*. The donor is veiled under the guise of anonymity, but essays in competition are to be forwarded to Dr. J. Collins Warren, 58 Beacon Street, Boston, Mass, not later than noon on the 15th February, 1882. The judges will be selected by Dr. Warren, and the following are the rules laid down for observance by intending candidates for the prizes:—

The essays must be legibly written and neatly bound. Each essay must bear a motto, and be accompanied by a sealed envelope bearing the same motto and enclosing the name and address of the writer. All the essays presented will become the property of the donor of the prizes, but none of them will be published. Any writer may, however, publish his essay, if he choose to retain a copy of it. The decision of the merits of the essays will be made chiefly from a practical stand-point, it being the object of the donor of the prizes to obtain suggestions by which a search for a cure for cancer may be instituted. The right is reserved to decline to award any prize in case no sufficiently meritorious essay be offered.

The Metropolitan Hospital Saturday Fund.

THE annual meeting of the board of delegates of this fund was held on Saturday last under the president Mr. Samuel Morley, M.P. The report, read by the retary and adopted by the meeting, stated that the council had the gratification of announcing that the total sum collected during the year had exceeded any previous effort, the increase over 1880 having been £1,540. The total collected for the year was £8,174, but the council were of opinion that that sum did not adequately represent the artisans of the metropolis fairly canvassed, and their earnest endeavours must be to impress upon working men the many advantages and great importance of the movement. The council dealt at length with the subject of the necessity of working men having a seat on the governing bodies of the metropolitan hospitals and

dispensaries, and also detailed the steps they had taken towards establishing an "Hospital Saturday Convalescent Home Fund." The chairman expressed general approval of the report. He thought there might be some difference of opinion as to whether the movement might not be weakened by losing the support of many of the working classes, unless their opinion was ascertained to be decidedly in unison with that of the council as to the convalescent home scheme, and suggested that that subject should be omitted from the report, and considered at a special meeting convened for that purpose, which suggestion was agreed to.

Ophthalmic Teaching in Dublin.

It will be in the recollection of our readers that the year before last, the Council of the Irish College of Surgeons, determined that a certificate of three months clinical instruction in ophthalmology should be required of every candidate for its licenses. In due course the special ophthalmic hospital, and the ophthalmic departments of general hospitals in Dublin began to receive pupils and issue certificates, and, moreover, some of the hospitals which had no such special departments, proceeded to do the same, although, their means of teaching ophthalmology were entirely mythical. It being then brought under the notice of the Council, that the issue of certificates of these hospitals was contemplated, the subject was again taken into consideration, and certain requirements were laid down which any hospital should fulfil before its certificates could be accepted as evidence of study. Thus difficulties arose with those hospitals which neither possessed the means of teaching the subject, nor were willing to provide themselves with such means, and at length, the College had again to take the subject in hand. Accordingly, it was proposed that all general hospitals should be disfranchised, *quoad* ophthalmic teaching, whether they possess special departments or not, and that no ophthalmic certificate should be accepted from any but a special hospital; a proposition which would have the effect of destroying the special department of certain hospitals in which, admittedly, the teaching was *bonâ fide* and excellent. This proposal was, for obvious reasons, warmly supported by the representatives of the special hospitals, and by those of one general hospital which was forbidden by its Act of Parliament to appoint an ophthalmic specialist in addition to its present staff, and by the influence of this coalition, the disfranchisement would probably have been carried out, but for an intervening motion that the requirement of an ophthalmic certificate should be abandoned, and that instead of it, a special examiner on the subject should be added to the Surgical Court of Examiners of the College.

This proposal has been approved by the Council, and thus, all certificates of ophthalmology are dispensed with.

PROFESSOR W. H. FLOWER, F.R.C.S., F.R.S., Hunterian Professor at the Royal College of Surgeons, has been elected a trustee of Sir John Soane's Museum in Lincoln's Inn Gardens, to fill one of the vacancies on the board, created by the deaths of Sir Philip de Grey Egerton, and M. F. Ouvry. The other vacancy is filled by the appointment of Mr. George Godwin.

The Meeting of the British Medical Association for 1882.

THE Fiftieth Annual Meeting of the Association will be held on August 8th, 9th, 10, 11th, 1882, at Worcester, under the presidency of William Strange, M.D. The Address in Medicine will be delivered by W. F. Wade, F.R.C.P., Physician to the General Hospital, Birmingham. The Address in Surgery will be delivered by W. Stokes, M.D., F.R.C.S.I., Professor of Surgery in the Royal College of Surgeons of Ireland.

The contemplated arrangements are as follows:—

On Tuesday, August 8th, there will be the usual service, at four o'clock, in the Cathedral, and a sermon by the Dean of Worcester (Lord Alwyne Compton). At eight the first general meeting will take place, in the newly restored Guildhall, when the President-elect will give an address.

Wednesday, August 9th, is proposed to be held as the Jubilee day *par excellence*. After the Address in Medicine, to be read by Dr. Wade of Birmingham, the Worcestershire and Herefordshire Branch, with their friends, will entertain the members of the Association at luncheon in the Shire Hall, which is calculated to seat 500 persons. At this meeting, Mr. Hastings, M.P., will read some remarks upon the life and work of his late father, Sir Charles Hastings, the founder of the Association. After luncheon, the bust of Sir Charles, at present being prepared by Mr. Brock, the sculptor, will be presented to the Mayor of Worcester, for preservation in some public place in the city, as a memorial of its late illustrious citizen. In the evening, the usual *conversazione* will be held, at which several unique objects of interest are expected to be open to inspection.

Thursday, the 10th, will begin with the Address in Surgery, which has been entrusted to Dr. W. Stokes, of Dublin. Sectional meetings will be held, and in the evening the usual dinner of the Association will take place in the Guildhall.

Worcester is the centre of a very populous district, and some hundreds of medical men will be able to come and go by rail daily, which will very much relieve the expected pressure upon the hotel and lodging house accommodation.

On Friday, the 11th, after sectional work in the morning the Association will be entertained by the Lord-Lieutenant of the county and Countess Beauchamp at Madresfield Court, near Great Malvern.

An endeavour will be made to wind up the work of the week by a performance of sacred music at the Cathedral, in connection with a special service, for which the kind sanction of the Dean has already been obtained by the President-elect.

THE Gulstonian Lectures will be delivered at the London College of Physicians, on the 3rd, 8th, and 10th of March, 1882, at the College, by Dr. W. Ewart. The subject is: Pulmonary Cavities; their Origin, Growth, and Repair. The Croonian Lectures will be delivered by Sir J. Fayer, on March 15th, 17th, and 22nd, on the Climate and Fevers of India. The Lumleian Lectures, on the Pathology of Inflammation, will be delivered by Dr. Bardon Sanderson on March 24th, 29th, and 31st. The hour for the lectures will be 5 P.M. on each day.

An Extraordinary Case of Suicide

TOOK place in Belfast last week. A man, named Stewart, was discovered in the yard of his house, his breast resting on the ledge of the ashpit, which is about four feet high. The head was hanging over in the ashes, and a small hatchet was lying between the hands. The scalp was removed for nearly five inches, and in the centre of this wound there was a fracture of the skull extending into the brain. The peculiar position of the wound is noteworthy, more especially as several blows of the hatchet were possibly required to inflict such an injury as that produced. The deceased, it may be added, was of somewhat weak intellect. The coroner, at the inquest held, said the case was most singular; but the only evidence they had led them to believe that suicide had been committed; and a verdict to that effect was returned.

The French Trichina Scare.

THE decree issued by the French Government, February 18th, prohibiting absolutely the admission of American pork on account of the danger from the trichina said to infect it, has given rise to great dissatisfaction and many complaints. It has interfered greatly with large commercial interests, and has pressed hardly upon the poorer classes, who in France make great use of pork. All this might have been borne had the danger been as great as it was at first represented to be, but it is now believed that it was in a great measure imaginary, seeing how little mischief has resulted in those countries which took no similar precautions. The decree was passed very precipitately, without the consultation with the Académie de Médecine which is usual on such occasions. The proposed organisation of laboratories for the microscopical examination of pork has never been carried out and it is expected that the decree will in a short time be withdrawn.

Neglect of Vaccination in Ireland.

THE medical officers of the New Ross Union have drawn attention to the great neglect of vaccination which exists in their districts; and their complaint, backed by a representation from the Local Government Board, have determined the guardians to take active steps by instituting prosecutions against the defaulters.

Fever Dens and Disinfectants.

PROBABLY the most effective and assuredly cheapest, costing less than one farthing a gallon, would be found to be a solution of chloride of lead, so strongly recommended by the late Dr. Goolden, of St. Thomas's Hospital, as the most simple, the most powerful and economical agent for eliminating sulphide of hydrogen from the atmosphere as well as from all organic matter in a state of decomposition or putridity. It is prepared thus:—Half a drachm of nitrate of lead, dissolved in a pint of boiling water, to be mixed in a pail of water in which two drachms of common salt have been dissolved. A cloth dipped in the solution and hung up in any place where bad odours prevail will sweeten the fetid atmosphere instantaneously; or thrown down a sink, w.c., or drain, or over a heap of refuse, will produce a like result.

The Administration of the Vivisection Act.

IT has now become an open secret that persecution by anti-vivisection zealots is not the only or the greatest difficulty which is now placed in the way of physiological workers in this country. It has, for some time, been known to a few, and is now becoming evident to the many that the administration of the Vivisection Act by the Home Office authorities is being carried on in a spirit never intended by the Act, and that, indeed, they are dealing in regard to the granting of licenses in a manner so arbitrary as to suggest they are actuated by partizan feeling rather than the rigid impartiality which ought to be displayed by officials in their position. We are adverse to giving currency to mere rumours, but we believe we are justified in stating that pressure has certainly been brought to bear from persons in high positions, with a view to biasing the authorities in favour of restricting vivisection; and whether this has had any effect or not, the fact remains that more than one of our most valuable physiological workers, upon whose personal labours questions of the highest importance depend for solution, have been directly or indirectly refused licenses which they might claim by right to perform necessary experiments. If this state of things continue in spite of protests quietly made, it may become necessary, by more active public measures, to demonstrate to all concerned that no one, however exalted their position can now-a-days be allowed by exercise of their personal influence, to interfere with the just and equitable administration of the law.

Proposed Alterations in the Indian Medical Service.

A PROPOSAL has been made by the Government of India to the Secretary of State to abolish the double appointments of Surgeons-General of the Indian and British Medical Departments, and to at once bring in the unification system to place the whole medical services under one head, who is to be in future styled the Director-General of the Medical Department in India, and receive Rs. 3,500 per mensem salary. It is estimated that this will effect a saving of Rs. 20,800 annually. The wants of India, as far as a medical establishment is concerned it is proposed to supply, by the formation of a Medical Staff Corps, which will be recruited by volunteers from the British Medical Service, and direct appointments from nominees who are selected by a certain number of the British medical schools. Our Lahore contemporary believes that the proposed reform has had its origin in Dr. Cunningham, the Surgeon-General with the Government of India; but it is believed the scheme has also received the imprimatur of Surgeon-General Crawford, who is on his way home to take up the post of Director-General of the Army Medical Department. As a reward for financial virtue and self-sacrifice, Dr. Cunningham has been nominated to the proposed Director-Generalship.

MR. CHARLES COPPINGER, F.R.C.S.I., and surgeon to the Mater Misericordiarum Hospital, has been elected to discharge the duties of the chair of Anatomy and Physiology in the Catholic University School of Medicine, filled by the late Professor Hayden in that school.

The Examiners at the Royal College of Surgeons, England.

At a meeting of the Council of the College on Thursday last, the following Fellows were elected members of the Board of Examiners in Anatomy and Physiology for the Membership and Fellowship of the College for the ensuing year—*For Anatomy*: Messrs. Walter Rivington (London Hospital), John Langdon (St. Bartholomew's Hospital), T. P. Pick (St. George's Hospital), and E. Bellamy (Charing Cross Hospital). *For Physiology*: Messrs. Henry Power (St. Bartholomew's Hospital), Marrant Baker (St. Bartholomew's Hospital), B. T. Lowne (Middlesex Hospital), Jeremiah McCarthy (London Hospital), and Gerald Yeo (King's College).

Enlargement of Irish Lunatic Asylums.

An Order in Council has been published authorising the expenditure of £20,000 on the enlargement and improvement of Londonderry Lunatic Asylum, and a sum of £1,800 to complete necessary additions to the Kilkenny District Asylum. This will provide accommodation for three hundred in the former institution, and one hundred in the latter.

Resignation of M. Vulpian.

At the meeting of the Paris Faculty of Medicine on last Thursday, M. Bouchardat read a letter from M. Vulpian in which he stated that he then resigns the office of dean.

Accordingly, after the perusal of this letter, the following resolution was passed: "The Faculty of Medicine express their regret that the Dean has resigned his appointment, and thank him for the services rendered them during his term of office." A warrant has appeared in the Official Journal appointing Professor Bélard, of the Faculty of Medicine.

An epidemic of typhoid of a somewhat severe type has broken out at Oldham in Lancashire.

M. ROBIN has exhibited before the Société de Biologie a specimen of blue urine, passed by a patient suffering from interstitial nephritis. The colour is supposed to be due to the decomposition of indican.

DR. G. M. STERNBERG ("National Board of Health Bulletin"), from observations made on the mud in the gutters of New Orleans, concludes that pathogenic bacteria are bred not alone in the bodies of animals.

THE managers of the Royal Institution of Great Britain have appointed Dr. J. G. MacKendrick, F.R.S.E., of the University of Glasgow, Fullerian Professor of Physiology for three years.

THE charge of conspiracy to defraud the North-Eastern Railway Company, mentioned in a recent issue, against Dr. Abrath and Mr. Michael McCann, of Sunderland, has been transferred by the magistrates' commitment to the next assizes. Bail for the appearance of the accused was offered by Dr. Potts, and accepted.

THE President of the Royal College of Physicians of London, Sir William Jenner, has appointed Dr. Long Fox, of Bristol, to give the Bradshaw Lectures at the College. Dr. Fox has chosen as his subject: The Position of the Sympathetic in the Causation of Disease.

THE Wyatt-Edgell Prize of £200 for the best essay on the Range of Heredity in Health and Disease, referred to in our last in connection with the Sanitary Institute of Great Britain, has been awarded to Mr. George Gaskoin. Twelve essays were sent in; the adjudicators were Dr. W. Farr and Dr. B. W. Richardson.

At Windsor, on Wednesday, the following members of our profession received from Her Majesty the honour of knighthood:—Dr. John Kirk, Her Majesty's Agent and Consul-General at Zanzibar; Mr. William MacCormac, late Secretary of the Medical Congress; Geo. Birdwood, M.D., C.S.I., Assistant Reporter in Statistics, India Office; and Mr. Erasmus Wilson.

FROM diseases of the zymotic class in the large towns, the highest death-rates per 1,000 were, from scarlet fever, 7·7 in Hull, 3·9 in Nottingham, 2·9 in Brighton, and 2·7 in Sunderland; from measles, 2·4 in Liverpool, and 1·7 in Leeds; and from "fever," 1·4 in Wolverhampton, and 1·0 in Leeds. In Hull 23 more fatal cases of scarlet fever were recorded, making 525 since the beginning of July. The 39 deaths from diphtheria included 21 in London, 7 in Portsmouth, and 5 in Glasgow. Small-pox caused 30 more deaths in London and its outer ring of suburban districts, one in Plymouth, one in Nottingham, and one in Liverpool; no fatal case was registered in any of the other large towns.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE INFECTIOUS DISEASES ACT IN EDINBURGH.—An important meeting was held in the Waverley Hall, Edinburgh, for the purpose of discussing the present mode of administering the 208th section of the Edinburgh Municipal and Police Act, 1879, under which medical practitioners, failing to report infectious diseases to the health officer, are liable to a penalty. Dr. Bowie, whose case has been fully reported and commented upon in the *Medical Press and Circular*, addressed the meeting in reference to his recent conviction in the Edinburgh Police Court for a contravention of this section, in that he failed to report a case of typhoid fever. His defence at the Court was that it was not a case of that fever; and even if it were, it was not infectious; and after quoting various medical authorities in support of this contention, Dr. Bowie said that it was infectious only to those who were exposed to the cause of the disease. He went on to say that the diagnosis of infectious diseases, before they were fully developed, was one of the most delicate duties of a physician, and it was preposterous that the officials connected with the health department of the city should entrust that duty to an ex-policeman. He (the speaker) did not regret having been made the first victim of the section, because it afforded the public an oppor-

tunity of seeing how the Act was carried out, and how unjustly it pressed upon the profession.

A WELL-MERITED REBUKE—THE ODIUM MEDICUM.—At the Sheriff Court, Kilmarnock, on the 7th inst., Sheriff Anderson issued an interlocutor in the action recently raised against Dr. Buchan, medical officer for the parish of Kilmours, by a man named Wm. Hannah, recently a pauper, though not suing *in forma pauperis*, for £50 damages, on the ground that the defender, Dr. Buchan, by careless and incompetent professional treatment of the pursuer's wife, had accelerated, if not caused, her death. An extensive bill of indictment was brought by the pursuer, including the evidence of five medical witnesses, and the defender had proceeded a short way in his case when the pursuer's agent suddenly abandoned the case. In these circumstances a formal judgment is not required, but the Sheriff thought it his duty to state that nothing had been disclosed which, in his opinion, justified this action, or that in any way affected the professional character of the defender as a well-qualified and attentive medical practitioner. The Sheriff added that he was sorry to see the proverbial *odium medicum* so abundantly displayed among the skilled witnesses, and he also regretted that the defender had been so improperly subjected to serious expense, which he could not recover from the pursuer.

HINTS ON HOME SURGERY.—The ninth of the series of lectures delivered in Glasgow under "The Combe Trust," was given on the 5th inst., in the City Hall, by Prof. G. H. B. Macleod. The subject was "Hints on Home Surgery." Prof. Macleod, at the outset, warned his audience that no part of the instruction given in his lecture was intended to interfere with the legitimate domain of the medical practitioner. The aim was rather to strengthen his hands in dealing with the sick. He desired to make some simple suggestions regarding the best management of those simple ailments that occurred in households. A large amount of harm was done by doing certain things before the arrival of a doctor, and while information would benefit people it would enable them to carry out better the instructions received from medical men. The professor then spoke at length on bruises, describing their nature and management, and pointing out some of the common errors which prevailed regarding their treatment. He also spoke on other ailments requiring surgical treatment, and at the close of an interesting lecture received a cordial vote of thanks.

EDINBURGH UNIVERSITY COURT.—At a meeting of the Edinburgh University Court, held on the 5th inst., *inter alia*, Dr. James Allan Gray was appointed class-assistant to the professor of medical jurisprudence; and the following gentlemen were recognised as teachers of medicine, whose lectures should qualify for graduation in medicine in the University, viz.:—Thomas Carnelly, D.Sc., lecturer in chemistry, Sheffield; John Wallace, M.D., lecturer on midwifery, Liverpool; and Chas. W. Cathcart, M.D., lecturer on anatomy, and teacher of practical anatomy, Edinburgh.

THE GLASGOW ROYAL INFIRMARY.—This old Institution is beginning to feel the effects of competition in public charity, in a greatly diminished income from the public, while curiously enough its directors in an appeal just issued, talk of the "laudable desire" of having a hospital on the south-side of the river. It would appear that the expenditure of the Glasgow Royal Infirmary this year will amount to £28,000, while the revenue cannot be estimated at more than £18,000, thus leaving a deficiency of £10,000. The appeal by the directors also states that last year the necessary expenditure for proper equipment and maintenance not only exhausted the whole ordinary and extraordinary

income, including upwards of £10,000 of legacies and donations, but also required that a sum of upwards of £4,000 should be withdrawn from the capital stock. During the past seven years the legacies and donations have been drawn upon to the extent of £25,000. This result is entirely as we have invariably predicted would happen. There is a limit beyond which the public will not support so-called charity, and there is a limit beyond which "charity" becomes a power of generalisation, and a social curse. These limits have been distinctly exceeded, and we make bold to assert that while the profession is thus pauperised by wholesale and indiscriminate medical "charity," *pari passu* the artisan class are demoralised and driven to intemperance and improvidence. This is in reality one of the most serious questions of the age. "The Royal" is suffering from the competition of the Western Infirmary; and but for the removal of the University to Gilmorehill, the "felt want" for the Western would never have been discovered. It is another phrase of professional greed, and of injustice to the medical profession at large. It is out of all reason to maintain that it requires two such large hospitals to meet the really just necessities of so large a community as that of Glasgow; and yet the directors of "The Royal" would evidently welcome a third!

THE EDINBURGH HEALTH SOCIETY.—The third lecture of this series which is being given in the Free Assembly Hall, was delivered on the 3rd inst., by Dr. Andrew Wilson. The subject was "Parasites in their Relation to Food and Health." Having given a few examples of the better known parasites, and their relations, among other things, to certain skin diseases, he proceeded to offer a popular classification of parasites by reference to the social relations between a lodger and his host. The first class he designated as being lodgers pure and simple, having shelter alone from their host. The second he distinguished as boarders, having not only shelter, but also feeding themselves at the expense of their hosts. And the third he denominated tenants by right, having as well as food and shelter, as it were a right to the host, by which he meant the class most typical of parasitic life, and which was found seated in one particular part and in no other part of the animal which it infested. Having given examples of all three classes, Dr. Wilson went on to consider more particularly those parasites which infest man, or which inhabit the human area, and these he considered in the order—(1) of flat worms, as the *Tania*; and (2) of round worms, as the *Ascaris*. He next related the life history of both of these classes of parasites, and laid stress on the important fact that these parasites required, in order to their development, two hosts. Taking the life history of the common tape-worm of man—*tania solium*—he showed that, in order to its attaining maturity in the human stomach or intestine, it must first undergo a preliminary stage of development in the pig. Similarly, the beef tape-worm, or the *tania mediocanellata* had its first host in the ox; and the *tania echinococcus*, which was the cause of hydatid disease in the human liver, we derived from the dog. Talking on the *trichina* in the class of round worms, Dr. Wilson sketched the life history of these parasites, and pointed out that, whilst we got the parasite from the pig, the rat probably gave it to the pig; and, in some way or other, the vicious cycle was completed by the rat getting it from man. The lessons which he deduced from what he had said on the subject of the parasites infesting man were the following:—(1) That they should see to the perfect cooking of all meat, including fish, from which they got a special tape-worm. (Applause.) It was ascertained

that a temperature of 140 degs. Fahr., maintained for some time, was fatal to parasitic life. (2) That all raw vegetables, especially those used to make up salads, should be thoroughly washed to guard against the eggs of tape-worms. (3) That they should never drink water from suspected sources, such as canals or ponds containing water snails, &c. (4) That the general health should be carefully looked to, inasmuch as parasites required a special soil for their development. (5) That care should be taken that dogs were not made a special source of infection; and (6) that personal cleanliness should be maintained.

PROFESSOR MACKENDRICK, GLASGOW.—Professor MacKendrick has been appointed Fullerian Professor of Physiology in the Royal Institution of Great Britain, an office which he can hold along with his chair in the University of Glasgow.

ABERDEEN UNIVERSITY.—At a meeting of the Aberdeen University Court held on the 7th inst. Dr. P. Buchanan White, Perth, was appointed examiner in medicine.

"THE EVANGELISATION OF FRANCE."—Such is the startling heading of a paragraph which appeared in the Scotch daily newspapers last week. We would not, and could not with propriety have taken any notice of this paragraph, but for the fact that the representative in Parliament of those Universities, which are connected with the medical profession, Glasgow and Aberdeen, took a prominent part in the meeting. As we cannot conceive a piece of grosser impertinence to one of the most enlightened nations in Europe than this, we feel somewhat humiliated as to the estimate which any intelligent Frenchman, in reading the paragraph in question, would form of the culture of our Universities. It is surely high time that the Universities should be rendered conformable to advancing intelligence. We are glad to believe that a large number of intelligent Scotchmen have no sympathy with the fanaticism which is too often, with good reason, charged against their country.

Obituary.

MR. DOUGLAS HEMMING, F.R.C.S., OF BOURNEMOUTH.

In chronicling the death of this gentleman we do so with the feeling of a personal loss, difficult to conceal. For the last few years Douglas Hemming's hand was frequently seen in the columns of this journal, most of our translations being from his industrious and facile pen. As evidence of his industry even when metaphorically speaking "at death's door" we may mention the fact that we received some "copy" for the press written in bed a few hours before his death, which melancholy event had actually happened before the letter reached us through the post. A more zealous, persevering, and honourable fellow labourer in the arduous duties of journalism it would be difficult to find, and there can be no doubt that had his young and valuable life been spared, he would have attained to a prominent position in the profession.

Three years since he was compelled to leave London and take up his residence in Bournemouth, on account of rapidly developing symptoms of lung disease; and to this change immediate danger was probably averted. At Bournemouth his accomplishments, gentle manner, consistent life, and his constant watchfulness for any opportunity of doing a kindly action, won for him the esteem of the many members of the profession, with whom he came in contact, whose sympathies were shown by many acts of kindness and solicitous care during his last illness. The predisposing cause of death was phthisis, but he actually succumbed to an attack of hæmoptysis on Friday last in the thirty-fourth year of his age. He had suffered

severely from sciatic pain for two months past, which seemed to point to some pelvic mischief, but he bore his suffering so uncomplainingly, that none but his attendant *confidés* had any conception of its extent and severity. Mr. Hemming was the author of several small works on throat diseases, otology, examinations, &c., and at the time of his death was contemplating the translation of a large German work on his favourite subject; but he has now passed away with the majority, leaving behind him an unsullied name, an honourable career, and the work of an unostentatious christian gentleman.

DR. PHILIP BEVAN, OF DUBLIN.

ONE more link of the chain which binds the passing generation of Irish Surgeons to those who are now the chief representatives of our profession in Ireland, has been severed within the past week by the death of Dr. Philip Bevan, which took place on Wednesday 7th, at his residence. Dr. Bevan was the son of one of the Vicar's Choral of St. Patrick's Cathedral in bygone days. After the completion of his medical education in the Irish College of Surgeons and the University of Dublin he took the License of the College and afterwards the Fellowship (1837) and the M.D. of Trinity College in 1845. His first recognition as an Anatomist of repute was his appointment to the Lectureship on that subject in the Dublin School of Medicine under Dr. Kirby, from which position he was promoted shortly afterwards to the Professorship of Practical Anatomy in the Royal College of Surgeons, which office he occupied until his death. For some years he held also a seat on the council of the same College, and during the chief part of his professional career he held the office of surgeon to Mercer's Hospital. He contributed to the *Dublin Journal of Medical Science*, a description of an apparatus devised by himself for putting up the fractured femur, and afterwards an able paper on "Scalds of the Larynx." In the *Medical Press* he also published an important case of fracture of the odontoid process of the axis. As an anatomist and a lecturer Dr. Bevan was noted for the minute accuracy of his descriptions and his lucid and quiet method of instruction. He was universally recognised by his professional brethren as a gentleman in every sense, and therefore incapable of any discreditable act, and he has left behind him the unanimous esteem of those who lived in his era and had the opportunity of observing his high qualities.

DR. MADDEN, OF BALLYCASTLE.

WE regret to announce the death of this gentleman on Saturday, December 3rd, at a comparatively early age. Dr. Madden was an M.D. and ex-scholar of the Queen's University of the year 1865, and had held the local dispensaries at Ballycastle for some years. Dr. Madden possessed considerable literary taste, and could give expression to his ideas both orally and on paper with a facility and grace that were to be envied. He was cut off in the prime of life, in the middle of a career—labouring, it is true, and testing to a constitution by no means robust—of great usefulness, and his death has cast a deep gloom over the district in which he lived, and where he was universally respected and loved.

DR. HENRY BERKELEY, OF MULLINGAR.

THE death is announced of this gentleman, who for a prolonged period has occupied the post of Resident Medical Superintendent of the Mullingar District Lunatic Asylum. He died at the mature age of 77, having been for a long time in failing health. No doubt he would long since have retired from office, but that the existing law of superannuation for officers in his position is so unsatisfactory, and the resignation of office involves a heavy sacrifice.

MR. JOHN REID, OF GLASGOW.

THE medical profession of Glasgow has lost by death a well-known and highly respected member in the person of Mr. John Reid, surgeon. Mr. Reid's death took place at his residence, 150 Renfrew Street, after an illness of about three weeks' duration, in its more aggravated form, though he had been ailing for the past eighteen months. The commencement of his last illness was ascribed by himself to a chill. Mr. Reid was a native of Glasgow, having been born in Gorbals in February, 1809. He was consequently in his 73rd year. For the first twelve years of his professional life Mr. Reid practised at Markinch, Fife, where he is still warmly remembered as a conscientious and painstaking medical practitioner. During the leisure time stolen from the active and multifarious duties of a country doctor, Mr. Reid wrote his work, "On the Philosophy of Death," which was well received by the press and in professional circles. Tired of country practice, he returned to his native city and commenced practice there. Some years ago he revived for a time a medical periodical published about forty years ago by Mr. Glen, surgeon, termed the *Glasgow Medical Examiner*, which, in conjunction with a friend, he edited. Intolerant himself of every form of abuse or meanness, the *Examiner* faithfully mirrored the character of its editor.

That the *Examiner* was faultless no one will maintain, especially in view of the steadily increasing commercial tendencies of the profession; but its faults were those usually incidental to genuine indignation at abuses, and a sincere, though possibly Quixotic, desire to remedy them. These, however, will be forgotten, while the good intentions of its conductor will linger long in the memories of those conversant with the medical history of the city and period. Mr. Reid was in many respects a man of striking character. It was quite in keeping with his robust mind that with every form of cant and hypocrisy he had no sympathy. His vigorous understanding led him to believe, as he had the courage to express, that he could form no opinion on those sublime questions which lie in that unknown tract which separates the finite from the infinite, and which ought to be regarded as a secret and individual covenant between man and his God, a conclusion, however, for which ignorance and intolerance have too frequently neither sympathy nor excuse. Mr. Reid performed during his long life many acts of unostentatious and secret goodness. He had sincere sympathy for suffering or sorrow, felt a warm interest in the early struggles of his junior professional brethren, was outspoken and fearless in his speech, and of untarnished honour. He will be much regretted by his patients and his numerous friends. The world would be better with a larger proportion of such men.

Novelties.

BERNHARDINE ALPINE HERB BITTERS.

Analytical Report by CHARLES R. C. TICHBORNE, LL.D., F.C.S., M.R.I.A.

I HAVE carefully examined this preparation as sent out by Mr. Wallrad Bernhard, and have submitted it also to a careful chemical analysis. The following are the most important heads of that analysis:—

It contains in the 100 parts—

Dry vegetable extract	2.55
Salts	0.17
Proof spirit	78.70
Aromatic oils, water, &c.	23.58

100.0

Bernhardine is perfectly free from mineral medicaments, and from drastic purgatives of any kind. It consists of a mixture of fluid extracts of a vegetable source, which are quite harmless, but which are, at the same time, powerful tonic bitters. It contains besides ingredients which render it highly carminative and grateful in affections of the stomach.

I am in a position to state that it does not contain any absinth, aloes, podophylline, or rhubarb, or any ingredients of such a nature that the continued use of it would be calculated to injure the system. Bernhardine is obtained entirely from herbs, which may be classed as bitter tonics, stomachics, and blood purifiers. It seems to be carefully prepared, and is pleasant to take to those who like bitters.

THE GENERAL PRACTITIONER'S POCKET SURGICAL CASE.

Messrs. LAWLEX, of Farringdon Street, London, have recently brought out a "Pocket Case for the Use of General Practitioners," much the same size as those now in use, but containing an infinitely greater variety of instruments.

Space being saved by an economical arrangement of combining parts of different instruments. Thus a handle is made to fit on to large sized scalpels, straight and curved bistouries, hernia knives, &c., and also on to a Butcher's saw some three inches and a half in length; and the male and female catheters are cleverly combined. Another metal case about the size of a caustic holder, contains a subcutaneous injecting syringe, two needles and a bottle for solutions. The clinical thermometer, which is

self-registering, is a curious novelty—it is flattened on two sides, so that when laid upon an incline it immediately ceases to roll, and when the mercury is observed at the line of junction of the two flat surfaces it is magnified to a breadth of nearly 1-16th of an inch, so that the degree reached by the mercury is readily observed, even in a dull light. The case throughout is very well made, and all its contents are of a serviceable character, many, as we have shown, being most ingeniously designed.

REDWOOD'S PREPARED COCOA.

WE can heartily testify to the admirable qualities of the cocoa paste prepared according to Prof. Redwood's plan. It possesses characters which place it in the first rank of articles of this description, while it exceeds all the samples we have hitherto tested in excellence of flavour, revivifying power, and ready digestibility. The paste formed by the milk and cocoa is perfectly uniform, and easily miscible in water; and in every respect this new preparation is a most successful improvement.

Royal College of Surgeons of England.—The following Candidates having passed the required examinations for the Fellowship, were, at a meeting of the Council held on Thursday Dec. 8th, admitted Fellows of the College:—

Baring, Harry Gilbert, M.B.Lond., Newham, Gloucestershire.
 Gill, Richard, M.B. Lond., Princes Street, Hanover Square, W.
 Griffith, W. S. Anderson, Guilford Street, Russell Square, W.
 Leaby, Albert William Denis, Warwick Street, Pall Mall, S.W.
 Lockwood, Charles Barrett, Serjeants' Inn, Fleet Street, E.C.
 Shattock, Samuel Geo., Downshire Hill, Hampstead, N.W.
 Uthoff, John Caldwell, M.D.Lond., Western Road, Brighton.

NOTICES TO CORRESPONDENTS.

PUBLIC ESTIMATION OF MEDICAL SERVICES.—The *Phar. Med. Times* says, that the State of South Carolina pays a very competent and estimable physician fifty-two cents (\$2.1d.) a head for treating thirteen hundred and eighty-three cases among the convicts of her penitentiary, and requires him to furnish his own conveyance and driver. The same State pays a lawyer five hundred dollars to go into an adjoining county and look into a faulty bill of indictment. Other states are much the same. But then, there are probably many doctors who would do the same work for half-price or less.

DR. — (Edinburgh).—In consequence of great pressure on our space we are compelled to hold over the New Regulations kindly sent us till our next.

DR. BOWIE (Edinburgh).—Reply to Dr. Littlejohn's letter arrived as we were at press. Proof shall be sent you before insertion.

A. W. W.—See reply to Dr. — (Edinburgh).

MR. HENRY LAKE.—With pleasure.

DR. TANNER.—If possible in our next.

ANTI-HUMBUG.—The suggestion is not original, a similar proposal being made by a correspondent in our columns nearly two years since. However, if it be carried into effect now that the prosecution of Prof. Ferriar has aroused the ire of our somewhat apathetic profession, it matters little to whom the credit of the first suggestion be due.

*MR. W. C. PAYNE.—A note has been made of the case, which will be utilised when opportunity arises.

ECZEMA OF THE SCALP.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—May I recommend your correspondent "M.D." to treat his cases of obstinate scurf after eczema capitis with careful anointing of the scalp with saccera (a pure colourless hydrocarbon made from petroleum, which can be procured of most chemists), and in addition five or six grains of red oxide of mercury and two or three minims of creosote, the latter being left out after the first week's treatment. Necessarily the scalp should be well washed with warm water and oatmeal, or yolk of egg, or pure glycerine soap, and dried before using the ointment, night and morning. "Clean, dry, and anoint" was the good maxim in such cases by the great Abernethy.

I am, Sir, your obedient servant,

Sackville Street, W., Dec. 1881. JAMES STUART.

CYPRUS AS A FIELD FOR PRACTICE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—I lose no time in answering my unknown correspondent in your issue for Nov. 23rd, and thus I hope prove to his satisfaction that I allow the truth contained in his *nom de guerre*. Private practice, I may tell him, is impossible in Cyprus without a fair colloquial knowledge of both Greek and Turkish; and as to the District Surgeoncies, he must make application to the Sanitary Commissioner, Nicosia, Cyprus, enclosing a list of his qualifications, and give some little information on the nature of his past experience. One other point, he ought to be a good horseman, as there is plenty of rough riding to do in many districts. Yours very truly,

W. HY. CULLEN.

DR. D. C. B.—It is one of those mushroom-like institutions which are springing up with such terrible persistency throughout the metropolis. Like you we have been told that the *co-dicant* physician makes a handsome income from the enterprise, and we have no reason to doubt the fact, considering the number of dupes who seem to flock thereto.

F. C. S.—We learn that an English translation from the original German has been undertaken, which will be ready by March or April next.

MR. J. S. R. is referred to the "Literary Notes and Gossip" column in our last issue.

CHEAP, VERY!

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—The annexed advertisement from the *South Hampstead Advertiser* is either a melancholy corollary of your remarks on the "overplus in the profession" in your issue of Nov. 23, or it is evidence of the philanthropic feelings of the rising generation who, with all their advanced studies, are determined to show the public how to appreciate them in their desire to do good, "of course, not for themselves." In my day an ignorant lobbolby would grin if he was offered a shilling for advice and medicine, even of the quality vended according to his enlightenment; and a cat and dog doctor in my neighbourhood who attended my dog a few days since charged medicine and visit 3s. 6d. each time, but the educated and legally-qualified member of the Royal College of Surgeons of England is willing to give similar services for a third this amount.

Yours,

ONE OF THE OLD SCHOOL OF DOCTORS.

SELF-SUPPORTING DISPENSARY, ST. JOHN'S WOOD.

Medical Officer: _____,
Private Residence: _____, N.W.

Hours of attendance Daily except Sundays.

Morning .. 11 to 1 o'clock.
Evening .. 8 to 10 o'clock.

Scale of Charges for ready cash only.		s.	d.
Advice and Medicine	1	0
Visit and Medicine	1	6
Vaccination	1	0
Midwifery	15	0

Messages for Home visits to be left before half-past eleven in the morning at the Dispensary.

Sunday attendance can be had at the Medical Officer's residence at the usual Dispensary charges.

Urgent cases occurring out of Dispensary hours receive immediate attention on application at the Medical Officer's residence.

The Medical Officer can be consulted daily, Sunday included, from 9 a.m. to 11 a.m. and 6 p.m. to 8 p.m. at the above charges for cash only.

[We have refrained giving the medical officer (who, by the way, seems to occupy the usual ubiquitous position of sole surviving partner in the concern, treasurer, secretary, compounder, &c., &c.) an advertisement of his name and address, as it might not be of moral or material support to him in our columns; the advertisement is, other-

wise, verbatim, except that we have not space for quarter-inch type.—ED.]

S. D.—The Secretaries of the Royal Irish University are, Dr. Meredith and Dunne, 25 Upper Merrion Street, Dublin. The list of Senate is too long for insertion here, but we can send it if you wish.

THE SOCIETIES.

ROYAL MICROSCOPICAL SOCIETY.—This evening (Wednesday), at 8 o'clock, Mr. A. D. Michael, "On Further Observations on British Urbitellids."—Mr. W. H. Symons, "On a Hot and Cold Stage for the Microscope."

HARVEIAN SOCIETY.—Thursday, Dec. 15th, at 8.30 p.m., Third Harveian Lecture: Dr. Alfred Meadows, "On Menstruation and its Derangements."

Vacancies.

Ballin Union, Crossmolina Dispensary.—Medical Officer, Salary, £128, and £20 as Medical Officer of Health. Election, Dec. 24. (See Advt.)

Birmingham General Hospital.—Surgeon on the Honorary Staff. Must be a Fellow of the Royal College of Surgeons of England, Ireland, or Scotland. Applications to the House Governor by Dec. 14.

Donaghmore Union, Rathdowney Dispensary.—Medical Officer, Salary, £100, and £20 as Medical Officer of Health. Election, Dec. 24. (See Advt.)

Loughborough Dispensary and Infirmary.—House Surgeon. Salary, £106. Applications to the Secretary by Dec. 17.

Monmouth Union.—Medical Officer for the Monmouth District. Salary, £40, with the usual extra fees. Applications to the Clerk of the Union by Dec. 30.

Sheffield General Infirmary.—House Surgeon. Salary commencing at £120, with board. Applications to the care of the Secretary by Dec. 17.

University of Edinburgh.—Examinerships in Clinical Medicine, Surgery, Physiology, Materia Medica, and Pathology. Applications must be lodged with the Secretary to the University Court before Jan. 14.

Appointments.

CHITTENDEN, T. H., M.R.C.S., House Surgeon to St. Peter's Hospital for Stone, London.

CORBOLD, H. F., L.R.C.P.Lond., M.R.C.S., Resident Obstetrical Officer to Charing Cross Hospital.

CRANE, C. R., M.R.C.S., Resident Surgical Officer to Charing Cross Hospital.

DURCAN, W. A. M.D., L.R.C.P., M.R.C.S., Resident Accoucher to St. Thomas's Hospital.

EVANS, E. W. J., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer of Health for the Wrexham Urban Sanitary District.

GURBIE, G. F., M.R.C.S., L.R.C.P.Lond., Senior House Physician and Chloroformist to the Westminster Hospital.

HAYNES, S. W., M.B., C.M.Ed., House Surgeon to the Birmingham General Dispensary.

LUNDY, L. F., M.R.C.S., Medical Officer of Health for the Staines Rural Sanitary District.

LYSTER, G. R. C., M.R.C.S., Resident Medical Officer to Charing Cross Hospital.

MCNALLY, F. C., M.R., M.Ch.Dub., Medical Officer to the Colton District of the Ulverstone Union.

MAONAKARA, H. W., M.R.C.S., Resident Obstetric Physician to the Westminster Hospital.

ROBBE, E., M.R.C.S., Medical Officer for the Shepperton District of the Staines Union.

SELLERS, W. H. I., M.B., C.M.Edin., M.R.C.S.E., Junior House Surgeon to the Royal Southern Hospital, Liverpool.

STONHAM, C., M.R.C.S., House Surgeon to University College Hospital.

Births.

LEE-STRATHY.—Dec. 6, at Harborne, Birmingham, the wife of Fredk. B. Lee-Strathy, M.D., of a daughter.

MIDDLETON.—Dec. 8, at Belzoe House, Mullingar, the wife of W. H. Middleton, Surgeon Westmeath County Infirmary, of a daughter.

Marriages.

BROWNE-BRODIE.—Dec. 1, at St. Peter's Church, Dublin, G. H. Browne, Esq., Ballingany, co. Limerick, to Alice, daughter of T. Brodie, M.D., Local Government Inspector, Cork.

Deaths.

BEVAN.—Dec. 6, at his residence, 38 Pembroke Road, Dublin, Philip Bevan, M.D.

COX.—Nov. 14, at Dikusa, Oudh, India, of cholera, Henry Lawrence Cox, M.D., A.M.D., aged 28.

FINCH.—Nov. 23, suddenly, at Stainton Lodge, Blackheath, Robert Finch, M.D., aged 64.

HENNING.—Dec. 9, at his residence, Glenalmond, Bournemouth, William Douglas Henning, F.R.C.S.Fd., &c., youngest son of William B. Henning, M.R.C.S., &c., of 26 Notting Hill Terrace, London, aged 33.

HENRY.—Dec. 4, at 10 Lowther Street, Whitehaven, Emerson Wilson Henry, M.D., M.Ch., aged 47.

HUNTER.—Dec. 5, at Belcoo co. Fermagh, Anna, the dearly-loved wife of Dr. Christopher Hunter; also, on the same morning, the infant daughter, aged 5 days.

JUNOD.—Nov. 26, at Onnaburg Street, London, Victor Theodor Junod, M.D., of Bonvillars, Switzerland, aged 76.

MARTIN.—Oct. 19, at Port of Spain, Trinidad, of fever, Alfred E. Martin, M.B.T.C.Dub., Colonial Medical Service, youngest son of James Martin, F.R.C.S.I., of Portlaw, aged 33.

MENSTRUATION AND ITS DERANGEMENTS.

By ALFRED MEADOWS, M.D., F.R.C.P. &c.,

Physician to, and Lecturer on Midwifery and Diseases of Women and Children at, St. Mary's Hospital.

Abstract Report of Harveian Lectures for 1881.

LECTURE II. (Concluded).

Menorrhagia.—This term must be carefully distinguished from metrorrhagia, a task rendered easy by reason of the essential differences between the conditions which give rise to one and the other form of discharge. The former appears only at the regular periods at which the menstrual flow is wont to recur, whereas the latter is constantly present in patients who suffer from it. The causes tending to the production of menorrhagia are to be found in such excessive changes in the ovary as bring about a state of hyper-stimulation of the organ, and these changes may be initiated either through the nervous, or through the vascular, system, or as a consequence of constitutional state. In the first case, excessive activity of the ovary results in an increase of function in the parts connected by nervous communication with it, and in these circumstances the blood supply will undergo variation commensurate with the changes set up. In such conditions of the general system as are observed in anemia, on the other hand, fluid is easily transfused from the circulatory organs, and goes to increase the natural discharge in menorrhagic patients. In such cases constitutional treatment, by iron and other appropriate remedies, must be encouraged; but there will be also encountered varieties of this class of case, each demanding special treatment, the nature of which must be decided on the merits of each as it presents. In this connection it may be urged that no drugs are, strictly speaking, definable as emmenagogues. Some substances which, under certain circumstances, act thus, may, at another time, and under varied conditions, ensure quite opposite effects, and therefore it should be regarded as an improper license of language to retain the term emmenagogues as fixed and invariable for any particular remedy.

Menorrhagia may be of different types. The congestive variety is encountered in florid women, and where it exists

the uterus will be found thickened, deeply injected, and from it will flow a blueish sanguineous discharge following the introduction of a sound. This condition will, moreover, be attended by dragging pains in the back, aggravated at the periods of menstrual flow, and which may be set down as due to a passive uterine hyperemia. The indications for treatment of such cases point to relieving the local congestion, for which purpose leeching is probably most suitable; and it may be repeated when required. General treatment is also called for, and particularly should the liver be attended to, since it is generally found to be at fault; likewise the digestive organs. The drugs to be looked to for benefit are such as ergot, nux, &c.

In ovarian menorrhagia the symptoms encountered present well-marked features to indicate the source whence they originate. There are no signs to indicate that the uterus is directly concerned in their production; pain is felt in the groins and down the thighs, and may also be experienced in the mammae, all these special signs of ovarian implication being absent in the form of menorrhagia previously described. As in it, however, the symptoms are aggravated at the menstrual period, and find an explanation in the physiological principles already enumerated. In these cases examination of the uterus reveals no abnormality connected with that viscus, but, on the contrary, pain and tenderness are always discoverable about the region of the ovaries, and at the same time possibly enlargement of the ovary itself. Also in these cases of true menorrhagia, the menstrual act occurs more frequently than it would under normal conditions of health, and this also serves to separate these cases from those of the uterine class, in which no such increased frequency is met with. The reasons for this peculiarity again are to be found in the structural arrangements and physiological influences at work in the parts affected, and a due understanding of them will determine the nature of the treatment best to be adopted. The guide to this is in the pathology of the state, and would lead to the neglect of astringent remedies, which, from their mode of action, are improper and unscientific, since attention is to be devoted immediately to the ovaries, the seat of the morbid process that is to be attacked. The most powerful agent that can be employed in this connection is undoubtedly bromide of potassium. It exerts a direct and considerable action on the ovary, inducing atrophic changes in it, and thereby effects speedy diminution in the amount of discharge set up by over-excitement in its tissues. The bromide exerts

specific influence over the nerves supplying the ovary, and hence the importance attaching to its use in all those instances where these nerves are in a condition of undue stimulation. Other treatment must of course be determined on the merits of each case; thus iron may be beneficially prescribed, and especially the application of anodynes locally in the form of pessaries. One of the most useful formulæ of this description is, Dr. Meadows explained, the following: coneia, 1 gr.; and atropine, 1-12 gr., in a pessary.

Menorrhagia consequent on organic changes in the uterus, may be considered as being amenable to treatment, except in those cases where such changes are due to presence of a malignant growth. The commonest form of such organic changes is so-called "sub-involution" of the uterus. This, the opposite condition to "involution," is readily understood when the sequelæ to delivery are considered. Following parturition the uterus is left in a condition of enormous hypertrophy, which however undergoes natural reduction, and in from three to four weeks in ordinary circumstances the organ resumes very nearly its natural condition. The process whereby this is effected is one of fatty degeneration, the uterine muscles, increase in which is that which produces the great enlargement of the organ, being thereby gradually diminished by resorption of the hypertrophied mass. The contraction of the muscular fibres themselves is a material operation, moreover, in bringing about the result; and anything which may interfere with due performance of such action will necessarily arrest the process of normal involution of the uterus, and set up a state of sub-involution, thus favouring the menorrhagic condition; and it is a matter of observation that this consequence of its existence may be present with greater frequency after abortion than when delivery takes place at the full term. In such cases, too, metrorrhagia will not rarely be discovered. The occurrences which mark this state of affairs clearly show how the discharge may be maintained during their existence; they include descent of the uterus, a consequence of its increased weight acting on the weakened supporting structures, and the increased tissue substance at the same time constitutes a much thickened wall, while the cavity of the organ may be even double its usual length. The presence of these conditions, taken together with the history of the case, enables a positive diagnosis to be immediately arrived at. Treatment is then comparatively simple. The indications are to relieve the stony, which is the most important depraved condition, and thus restore the structures to a state in which the arrested process may once more be pursued to the natural termination.

In those instances, however, where the history given is that of a chronically inflamed hypertrophied uterus, the treatment resorted to will be different, inasmuch as the operating causes are shown to be other than in the variety just considered. In order to meet and arrest menorrhagia due to sub-involution, attempts are directed to inducing tonicity and contraction in the uterus, for which purpose such remedies as ergot, cinnamon, nux, quinia, &c., will be found serviceable. Locally, the application of galvanism, if persisted in with a determination to overcome the menorrhagia, will sooner or later be attended with relief of the symptoms, and is well worthy of most careful trial.

Intra-uterine Growths may be either malignant or non-malignant in character, and the symptoms of their presence may include both menorrhagia and metrorrhagia. The nature of the discharges, however, may undergo very considerable alteration in accordance with changes taking place in the uterus itself. It should be carefully remembered, also, that over frequent ovulation will give rise to excessive secretion, the discharge of which may be mistaken for evidence of a menorrhagic flow. The phenomenon of periodicity, in all such cases, will serve to arouse suspicion as to their real nature, and the further influences exerted over the discharge by, and through, the ovaries, will afford confirmatory proof concerning them.

When the fact that the uterus does contain a growth of some kind has been accurately established, then, if it be malignant in character, further decision respecting its special nature will be materially assisted by the signs its presence affords. Thus, the situation and character of the pain experienced by the patient will be a valuable means of diagnosis in cancer of the cervix, scirrhus. Absence of painful sensations is by no means of uncommon occurrence, whereas in that description of cancer which is found invading the fundus uteri agonising pain is an all but invariable accompaniment, and it is never unattended by severe attacks

of pain. The knowledge already gained of the nerve distribution of the uterus will render the explanation of this difference a simple matter, as also it will indicate why operation on the neck of the womb may be resorted to without the fear of unduly disturbing the patient.

There is also a distinct connection between the pain experienced and the amount of discharge from the organ. Thus the greater the degree of pain the smaller is the flow; and the more considerable the discharge the less excruciating is the pain, or the greater, in other words, the freedom from pain. This correlation is of immense value as a means of diagnosis in case of cancer uteri, and will often become a guide in the question of operative procedure. Whenever a copious discharge is met with in patients who suffer but little, and in whom the presence of a cancerous growth has been made out, then the conclusion is justified that the cervix is the part implicated, and never the fundus of the uterus. Again, as to the appearance of the discharge. This will be of a dirty foetid nature, only in cases of malignant tumours, unless it be that it arises from a sloughing sore, or from pent-up secretions. In malignant cases it is always present.

The presence and nature of the growths under consideration need to be made out with care and certainty ere their treatment can be hopefully resorted to; and for this purpose several modes of investigating them must be pursued. Several aids to physical examination can be employed, and the chief may be noticed in succession. The fingers of the operator are the most important of all these aids, by them the size, consistence, &c., of the cervix are at once determined; they unerringly ascertain the presence of growths on the walls they are in contact with, and as well, too, they will enable a determination to be arrived at concerning the preservation of the tumour, whether that is it be properly associated with one or other of the groups of cancerous growths, or is of non-malignant origin, as, e.g., polypi, &c.

At this point Dr. Meadows proceeded to describe at some considerable length the numerous tumours to be found in the uterus under abnormal conditions, and the way in which they would be found productive of menorrhagia. From this subject he then passed to a consideration of the second most important aid to physical examination, the *uterine sound*, which he likened to an elongated finger, by the employment of which valuable information might be gained concerning the length and extent of the uterine cavity, the situation and nature of growths in its walls, &c., &c. He next enumerated the various kinds of tents, sponge, tangle, &c., also of service as aids to examination, which acted by dilating the canal of the cervix, and so admitting freer inspection of the interior of the womb.

In respect of *interstitial tumours* of the uterus, Dr. Meadows strongly inclined to the view that *enucleation* is the most appropriate treatment to adopt towards them; and he expressed his conviction that in the future it would be universally employed. In the majority of cases the tumour is, he explained, so free of the proper tissue of the organ as to admit of being safely everted, and he had been surprised sometimes to find how thin the wall could be which permitted this to be done with absolute safety.

THE EARLY DETECTION AND TREATMENT OF DISEASE OF THE HIP-JOINT. (a)

By EDMUND OWEN, F.R.C.S.,

Surgeon to St. Mary's Hospital, and Senior-Assistant Surgeon to the Hospital for Sick Children, Great Ormond Street.

(Continued from page 512.)

The next diagram upon the wall shows the anterior superior spine of the ilium tilted down in order to diminish the amount of the joint tension, and it also shows how the loins have to arch backwards so that the centre of gravity of the erect trunk may not be thrown too far in front of the basis of support. This arching, or lordosis as it is grandly called, becomes permanent if the ilio-femoral trouble, for which it is the mechanical compensation, be not obliterated. It will be well to place the fingers under the spinous processes of the

(a) Read before the Harveian Society of London, November 3, 1881.

lumbar vertebrae whilst this depression of the femur is being undertaken; nor must it be forgotten that the arching is at times associated with psoas abscess.

I can imagine that in certain cases of hip joint disease the arching is not sufficiently characteristic or diagnostic, so that the surgeon may be led to seek for other and more definite signs; but whatever his method, he should, in order that he may secure the confidence of the child, begin by manipulating the sound limb. He will notice the amount of the furrow of the groin on the two sides, and will probably find that on the affected side it is a good deal effaced by the bulging of the capsule beneath; and by thrusting the finger over the front of the joint he will increase the intra-articular pressure, and so gently draw forth some complaint from the child. But there is no diagnostic method better calculated to increase the intra-articular pressure than that of gently rotating the thigh outwards, so as to put strain upon the ilio-femoral ligament. This movement drives the head of the femur up into the depths of the acetabulum to press upon the swollen and tender ligamentum teres. Rather than allow of such a pain-producing movement, the whole of the pelvis travels round with the femur; indeed, that bone seems to act as a handle to the entire body. This fixation of the femur is due partly to muscular action, partly to the distension of the capsule which has rendered the joint fixed and solid. (This injected specimen shows the firmness of the distended capsule, and shows how it is that even in the early days of hip-joint disease the administration of chloroform does not always suffice to allow of the limb being brought straight, without the arching in the loins accompanying it.)

And now we will turn the child gently over, so that we may examine the gluteal region. We will notice that the buttock is rather wider than on the sound side, on account of the fluid in the joint having driven the head of the femur from the depths of the acetabulum. (This effect can be imitated by injecting fluid into the joint through the pelvic perforation.) Another sign of joint disease is the intolerance to the pressure of the finger in the interval between the tuberosity of the ischium and the great trochanter; that is, over the region of that part of the inflamed synovial membrane which is bulging on to the back of the neck of the femur. Before I leave this part of the subject I would like to direct your attention to a most delicate indication of there being, or of there having recently been, something wrong with the joint; it is the change in the arrangement of the lines of the gluteal folds and those of the inner borders of the upper part of the thighs. The change itself results from the flexion of the thigh, the extrusion of the head of the femur (and with it the great trochanter), and from the flabbiness of the disused muscles.

soon as the contour of the buttock is altered by the intra-articular effusion—and altered it must be—the arrangement of these lines or folds is disturbed, and the symmetry is lost. This second scheme shows the alteration in no exaggerated degree. I shall venture to call this the escutcheon-sign of the disease. It is particularly useful in the examination of those young subjects in whom a slight inflammation is present, or where inflammation has passed happily away before advice is sought. To see if the term is appropriate I looked out the word in Webster. There I find that escutcheon is a "shield; the part of a vessel's stern on which her name is written." The name that is written on this altered escutcheon is "Hip-joint Disease."

Now we must pass on to the subject of the treatment of the early disease. Whether the affection be slight or severe the child must be put to bed, where, possibly, after a few days, complete restoration may be obtained. But so satisfactory a result must not be expected; very probable is it that the treatment will extend through weary months, or even years.

We will imagine, in the first place, that the local trouble is not much; that the limb comes down flat on the bed without any loin aching, but that movement between the bones distresses the child. In that case a well-made Thomas's splint may be applied. It ensures absolute rest of the parts, being a flat and light wrought-iron bar, which, running behind the limb is clamped on to the ankle, thigh, and thorax. Those made by Sanders, 23 Osnaburgh Street, are the lightest, best, and cheapest that I have yet seen.

When the child has lain on the splint for some days, weeks, or months, as the case may be, and is not only used to it, but even likes it, he may be allowed to learn to go about on crutches, provided always that the foot of the affected side does not touch the ground. And to secure this he must wear a raised boot upon the other—the sound—side. He must, of course, be still employing the Thomas's splint. If he is careful, and is not permitted to be on the crutches for more than a short time—say half-an-hour in the morning, and the same in the afternoon—he will quickly attain proficiency. But if the femur is rigidly bent towards the pelvis, and refuses to be brought straight, the weight stirrup and pulley must be used to bring the limb gradually down. It is not necessary, I know, to say how the stirrup should be applied, but I may venture to give a hint as to how the extending force may in these cases best be used; and for that purpose I will once more direct your attention to the diagram which shows the arched loins, and will suggest again, that if the weight be so brought to bear on the limb, as at once to bring the rigid thigh flat upon the bed, the apparent improvement in position can be effected only by increasing the arching of the loins from off the mattress.

Whenever the weight is applied, or being adjusted, the hand must be run beneath the lumbar spinous processes to see that they are in a straight line. And the rule should be followed to keep the line of traction always in the axis of the femur. Sometimes it will suffice to place a pillow beneath and for the support of the knee. At other times a large and firm wedge-shaped junk will best serve for keeping the limb raised to the proper height. Such a junk may be almost as large, though rather more pointed than an ordinary sugar loaf. The apex of the wedge will of course come up to the buttock-fold, whilst the base lies just beneath and supports the heel. In the next diagram I have shown in dotted outline the size and position of the junk, but you will see that the thigh is yet too much flexed upon the abdomen for it to be of use. In that case, which is an extreme one, the pulley has to be raised to the level of the top rail of the bed in order that the rule may be observed of keeping the traction in the axis of the femur. As the thigh comes down, so gradually may the pulley be lowered.

One point which I would suggest as well worthy of

Here I show a scheme of the normal arrangement of these lines, a shield-shaped figure being marked out. Notice how definite and regular is the shape. But as

discussion by the Society is the propriety of applying blisters, the actual cautery, or leeches over the region of the hip-joint in the early days of the disease. For my own part I would say that I am opposed to all forms of counter-irritants in the circumstances, but that I consider the application of two or three leeches over the acutely inflamed joint very judicious. But the hip-joint lies so deeply placed amongst the surrounding muscles that local depletion cannot be expected to have as direct an influence upon the capillary engorgement as it would have, for instance, in the case of the knee or ankle. The hip-joint is almost beyond the pale of direct therapeutic influence, but what is worse, being so far out of sight, it is also apt to be out of mind; at any rate it often becomes a matter of niceness, if not of difficulty to give a decided answer as to whether it is sound or not.

To return to the matter of counter-irritation, I would say that I have at times employed it in certain painful conditions, but rarely, if my memory serve me, when the disease was young. I would maintain that counter-irritation should never be resorted to as a by-chance, but only after absolute rest had been steadily employed, and when other favouring influences had failed to give entire relief.

Of the merits of ice and iodine I know but little, but I may perhaps state that the fat boy, whom you have seen here this evening, on whom six months ago I performed excision of the hip-joint, was treated for many weeks in the early stage of the disease by a neighbouring bone-setter by the combined influence of ice, iodine, and promises unfulfilled. Ice had probably the effect of postponing the result of his shameful endeavour to "put the bone in;" it did not entirely preclude it. (I wonder if it was a qualified member of our profession who gave the anæsthetic when this disgraceful "attempt at reduction was undertaken.")

Another point upon which I would lay great stress is that when the child is being submitted to the influence of extension he must not be allowed to sit up in bed, not even for a moment, for such an attitude encourages that very mal-position against which we are waging a gentle but determined warfare. Due restraint is, I grant, irksome at first, but, like children of maturer growth, our little patient calmly settles down, (like his femur also), under the influence of a therapeutic providence. And as affairs begin to improve, or are advancing towards recovery, the instrument maker may come and measure him for a Thomas's splint, which is to be applied when the limb is straight. In time, too, the crutches and the high-boot may be allowed to arrive, until at least the child's cot, near which these various apparatuses are placed, looks like a shrine about which have been hung the votive offerings of grateful convalescents. Nor are such matters devoid of therapeutic influence upon the little patient; to look at them opens up a long vista of happy prospects, and turns his submissiveness into absolute contentment.

NERVE STRETCHING IN TETANUS— SUCCESSFUL. (a)

By W. I. WHEELER, M.D.; T.C.D. F.R.C.S.I.,

Surgeon and Lecturer on Clinical and Operative Surgery to the City of Dublin Hospital; Member of Council Royal College of Surgeons.

THE operation of nerve stretching has, of late years, been often practised, and has been a subject of much interest to, and investigation for, most practical surgeons, although the case I am about to record, viz., nerve stretching in acute traumatic tetanus, scarcely as yet comes within the present literature of the operation, only

one case, as far as I know, being fully and well recorded of nerve extension in tetanus. I feel that a limited epitome of one or two of the earlier accounts will render this communication more interesting. Truly, many cases recorded in times past bear on the operation of stretching nerves, although a different explanation is given, to what now, they would seem to require; this is well exemplified by a case of secondary amputation performed by Mr. Langstaff, for a neuralgic stump, in which he states, he drew out the nerves before dividing them, and that the neuralgia was cured. He performed this operation in order that the nerves might be free from cicatricial tissue, but it is reasonable to assume that the favourable result was due to the nerve stretching.

Amongst the earliest operations of this kind, we find the following remarkable case, published by Professor Nausbaum (*Deutsche Zeit. f. Chirurgie*) which I will briefly record:—

A soldier, æt. 23, received a blow with the butt end of a rifle, on the nape of the neck, and another on the left elbow. At the former place an abscess formed and was opened and duly healed up again. He afterwards suffered from contraction of the left pectoral region, the whole left upper and fore arm, and hand of the same side. This contraction was a spasm, which became more violent the more attempts were made to oppose it; besides, there extended over all the dorsal aspect of the fore arm, an anæsthesia, which increased to such a degree, that deep incisions, tenotomies, &c., could be practised without any pain to the patient. The spasms varied in intensity, and were so violent that for hours the finger tips were driven into the palm of the hand, the great pectoral muscle was always as hard as stone. Numerous were the remedies applied—Iodine, mercury, belladonna, and the constant and interrupted galvanic currents, &c., &c., without affording the slightest relief. Professor Nausbaum operated after this manner:—

The patient being under chloroform, an incision about three inches long was made over the site of the ulnar nerve, which was lifted, gently extended, and then replaced. The wound was cleansed, and closed by suture. A second incision was made in the axilla over the artery. The nerves, which closely surround the vessel, cutaneous as well as muscular, were drawn out one by one, the median, radial, and ulnar being recognised to a certainty by the twitching of the muscles of the finger, which they respectively supplied, and after being subjected to the same treatment as the ulnar nerve, were replaced and the wound brought together; lastly, an incision was made over the left clavicle, such as would suit the ligation of the sub-clavian, the platysma having been divided, the four lower curved nerves were isolated, traction was exercised upon each, and each was followed with the tip of the right forefinger to its point of exit from the vertebral column, here each was pushed upwards and downwards, and right and left. A good tug at the nerve in a direction, although it were to be pulled away from the spinal cord, completed the operation. The four upper curved nerves were not touched, as there had been no indication that there was any lesion of the phrenic nerve at its origin. The operation was successful beyond expectation, the spasms did not return, the forearm and fingers could be flexed and extended at will, and the skin of the arm, which before the operation was so devoid of sensation that puncture and the application of hot sealing wax were painless, had regained sensation to such an extent that the patient, even when blindfolded, could localise the slightest touch. The man made a good recovery, although he had of necessity to run the gauntlet of pyæmia, nearly always present, then rife in Nausbaum's hospital.

Close after Nausbaum, we have cases recorded by Billroth, and the late Mr. Callender. The observations of the latter gentleman, well worth perusal, may be found in the Clinical Societies "Transactions"; were it within the province of this communication, I could myself

(a) Read before the Surgical Society of Ireland. The discussion will be found at page 527.

relate cases with satisfactory results from stretching the supra-orbital, facial, spinal accessory, and external popliteal nerve, and quote published statements, that substantial and advantageous results have followed the stretching of the ischiatic nerve in Duchenne's paralysis. That relief may be obtained in such cases is quite tenable, but the pathology of the disease negatives the assertion, that more than that can be gained; the notes of the following case under my care, were chiefly taken by the house surgeon:—

Teresa M., *et. 8*, a strong, healthy child, was admitted to the City of Dublin Hospital on the 10th of October, 1881, suffering from what she stated to be a sore finger. Eight days previous to admission, a stone fell on the middle finger of her right hand, bruising it severely; the finger had been dressed and placed on a splint by the medical man who saw the case, but, owing to the neglect of the parents, the dressing had not been changed for six days previous to admission. On examination the end of the finger was found to have been destroyed by gangrene, and fell off with the foul dressings, leaving the end of a fractured phalanx (the second) protruding, this fell away at the joint next day. The patient did not complain of any pain in the hand, but did of pain in the back, which was stated to be caused by a fall off a table. When the question of making a neater stump was under consideration, it was noticed that the patient lay in a peculiarly stiff way in bed; operative procedure was postponed, commencing tetanus was diagnosed, and was followed by the train of usual symptoms. The muscles of the back and abdomen became rigid, the sterno-cleido, mastoid, and trapezius muscles were also in a state of rigidity, the risus sardonius was well marked, and strong tetanic spasms backwards (opisthotonos) contorted the child's body; the spasms came about every two hours. The treatment was locally, opiate stupes applied over the wounded finger, enveloping the hand as far as the wrist, and ice to the spine and head. Internally, bromide of potassium, belladonna, and canabis indica were administered; chloral hydrate was given by the rectum to produce sleep; the nourishment was chicken broth, milk, and beef-tea. The room was carpeted, and a screen placed round her bed. There being no improvement from the above treatment, but, on the contrary, the patient getting worse, and the spasms increasing in intensity, on Sunday morning the 15th Oct., I determined to stretch the median nerve in the forearm; the child being put under the influence of chloroform (my colleagues, Dr. H. Benson and Mr. Butcher were present), I made an incision about two and a half inches long in the forearm and quickly caught the median, closely applied to the posterior surface of the flexor digitorum sublimis appeared somewhat red. I stretched the nerve between two fixed points, and also pulled it firmly downwards towards the wrist joint in its long axis; while under chloroform the tetanic spasms stopped. The wound was brought together by means of strips of American rubber plaster, and quickly healed. No deleterious carbolic spray was used, but there was minute attention paid to surgical cleanliness before bringing the edges together. For two hours after the operation the spasms increased a little in frequency, but gradually became less frequent. Never were they so intense from the time of the operation, and from this time the recti muscles of the abdomen became relaxed. The temperature was always normal or sub-normal, (a) and the pulse ranged from 60 to 70 per minute, save on two occasions when it was 110 and 90 per minute. The further history of the case was a gradual progress towards recovery, the last recorded twitch, for it could not be called a spasm, was on the 20th of October. The patient is now quite well and she has returned to the country. In her photograph (here produced) can be seen, on close

examination, the line of incision. On testing the sensation in her right hand with the aesthesiometer, three days before leaving the hospital, it was found unimpaired, as also motion.

As before stated, the only well recorded case of nerve stretching in tetanus that I can find is that reported by Dr. Paul Vogt, who cut down on the brachial plexus, and pulled it in a case of traumatic tetanus occurring fifteen days after an accident which inflicted wounds on the palmar and dorsal aspects of the same hand; he states that there were attacks of the most powerful opisthotonos, that there was no pain in the forearm or arm, not even tenderness, and that the wounds were healthy and granulating. Slight spasms occurred in his case on only two occasions after the operation, but there was some stiffness of the jaws remaining. In discussing the treatment of traumatic tetanus, it can be done under two heads, viz., by operative measures, and medicinal measures. The results of treatment are so unsatisfactory as to justify any reasonable line of action that has a chance of success. Under medicinal agents we could not well be at a loss, as almost every medicine in the Pharmacopœia has, some time or other, been prescribed for this affection. On the contrary, operative measures are much more limited. I may name amputation, actual cautery, division of nerve trunks, and nerve stretching; of these I selected the latter, believing it to give the best chance to my patient. That the pulling and pulling forcibly of a nerve is not followed by any untoward results is manifest not only from the cases I have quoted, but from those recorded by Billroth and others, where large nerves have been exposed and roughly handled, neither was their motor power nor their nutrition impaired; but when we come to consider how the stretching of a nerve relieves pain, how it stops tetanic spasms arising from central irritation with our limited physiological knowledge of the spinal cord it is difficult to offer an explanation.

Now Flaubert and Le Bret have shown that inflammation of the spinal cord may follow as a consequence of irritation of the brachial plexus, and Brown-Séquard has confirmed this, and illustrated the extension of irritation through a nerve trunk to the spinal cord; developing symptoms through the extension of the mischief in the nerve centres, to parts removed from those first involved, hence, the necessity for the recognition and discerning between a peripheral and a central irritation. Nausbaum has made a speculative statement, that in neuralgia the stretching is of service by altering the relations of the nerve fibres and improving their nutrition, but this would not account for the cessation of spasms due to tetanus. It would seem that as neither sensation or motion, even in violent nerve stretching, is impaired, that it must be a temporary numbing of the nerve, by which numbing there is a cessation of the power of the nerve fibres to transmit abnormal impressions, and thus the centres have time to resume their normal condition and control. *Appropos* of this, Dr. Brown-Séquard has proved that if a nerve is exposed and frequently washed with ether it will be unable to transmit any irritation. But, it may be asked, will not the division of the nerve break the chain of these abnormal impressions. I think experience teaches us the contrary, for if there is a neuritis present, as I believe there was in my case, the limits of the affection are unknown, and in the cases recorded by Drs. Sands and Seguin, in which portions were cut out from the brachial plexus, the nerves of which were found matted together, the patient was only relieved as the neuritis probably extended further on the central side. Knowing these facts, I was prepared to stretch the brachial plexus of nerves, were I not convinced as I was by the relaxing of the abdominal recti, and afterwards by the lessening of the spasms, both in frequency and intensity, that the amount of stretching I practised would be sufficient; but, in thinking over the case, it has occurred to me that had I stretched the brachial plexus, like Dr. Paul Vogt's, the spasms might have ceased almost immediately. I deem this case one of much interest,

(a) The highest temperature recorded in tetanus is that by Wunderlich. Even the thermometer stood at 112 Fahnt., and the temperature continued to rise for an hour after the cessation of all signs of life.

and being anxious to know if there had been any cases of nerve stretching for tetanus in the sister Island that I could quote here to-night, I inquired of Mr. Bryant, who informs me he cannot give me reference to any case of nerve stretching for tetanus in London.

Clinical Records.

TRIM FEVER HOSPITAL.

Case of Uremic Convulsions in Scarlatina treated by Hypodermic Injection of Pilocarpine.

Under the Care of FRANCIS J. O'REILLY,
L.K.Q.C.P.I., &c.,

Physician to the Hospital.

THE recent unpleasant legal proceedings relative to the administration of the above drug, by which it was sought to inflict grievous injury on the professional reputation of a distinguished member of the profession, have induced me to place before your readers the following brief, though, I hope, not uninteresting notes.

J. H., *st.* 14, was admitted to the Trim Fever Hospital on October 5th, suffering from scarlatina. The case presented no feature of interest beyond the ordinary course of that disease till the morning of October 26th, when I was informed that the boy had had fourteen fits during the night.

At the time of my visit, about 10 a.m., the boy lay quite insensible, and two convulsive fits manifested themselves whilst I was making inquiries about the case. A small quantity of urine, about half-a-wine glass full was shown to me by the nurse as the product of the night which, on the application of heat, gave abundant evidence of the presence of albumen. The case was most unpromising, as from the insensible condition of the patient the administration of internal remedies was rendered impossible; besides, the sufferer could not long withstand the frequency and severity of the fits.

Half a grain of pilocarpine in solution was, without delay, injected under the skin of the arm, the patient was enveloped in a sheet wrung out of warm water and two heavy blankets well heated placed tightly round him. The physiological effects of the drug almost immediately developed themselves, the patient's face became flushed, saliva literally flowed from the mouth, and the skin was soon bathed in profuse perspiration. After the lapse of an hour from the introduction of the drug into the system the boy regained consciousness and took a little brandy and warm milk. The convulsions did not return, and thus time was given to get under the kidney mischief which had so suddenly threatened the life of the patient.

The boy made an excellent recovery, and was discharged, cured, November 28th.

Department of Lunacy.

HOMICIDES IN LUNATIC ASYLUMS.

THE occurrence of a fatal affray between lunatics in the Derby County Asylum, so soon after a similar event in the Cambridge County Asylum, is likely to lead to a good deal of ribald criticism on the administration of our lunatic hospitals, and to suggestions more or less wild for the avoidance in future of such deplorable misadventures. Of course every occurrence of the kind should be strictly inquired into, and closely criticised, blame being bestowed or penalties inflicted, wherever it can be shown that there has been contributory carelessness or culpable negligence,

but it is worse than foolish to make the mere fact of a homicide having occurred in an asylum, the pretext for a general attack on those institutions and the authorities, who are charged with their control. In asylums, as in other households, accidents will happen, and to anyone who dispassionately and with adequate information inquires into the matter, the wonder must be, not that homicides are so frequent in these establishments but that they are so few in number. On the 1st of January last there were 54,445 insane persons shut up in lunatic asylums in England and Wales, representing, of course, the quintessence of the uncurbed passion, reckless violence, and irresponsible caprice of the country, and in all this vast crowd of lunatics there was practically no mechanical restraint. And yet the record of homicides in the establishments containing these lunatics for the previous twelvemonths was actually less than it was for the same period in convict prisons, containing, only one-eighth of their population, and in which every necessary measure of restraint, seclusion, and repression is unhesitatingly resorted to.

The truth would seem to be that an occasional homicide in an asylum is one of the inevitable consequences of the modern and humane method of treating the insane. If lunatics, many of whom are charged with dangerous impulses, dominated by delusions, or liable to sudden outbursts of fury, are to be allowed to walk about unbound, to associate together as in a great club house, and to use all the tools of industry and of domestic convenience, then murderous incidents must be looked for from time to time. No diagnostic skill nor foresight can absolutely prevent them. The tact and vigilance of trained nurses and attendants, even when zealously exercised, will not always avail to obviate them, as was notably illustrated in the recent case at the Cambridge Asylum where the murder was committed in the presence of experienced and trustworthy attendants who had no time to interfere before the deed was done. One blow given suddenly by a sly and dangerous epileptic, on the side of the head of a feeble melancholic patient, sufficed to cause instant death, and it is difficult to see what possible blame could attach under such circumstances to the attendants who were close by at the time, and were so watchful that they had overpowered the aggressor before a second blow could be struck. No doubt all such calamitous events could be effectually obviated. Let all asylum medical officers be given to understand that we must hear no more of such incidents, and that at any cost they must be prevented, and the instruction will be fulfilled, but by the infliction of an amount of misery and evil that the country will tolerate far less than an occasional incident. In order to carry out the mandate, the non-restraint system must be abandoned, solitary confinement must be largely resorted to, and a severity of discipline must be introduced into asylums in painful contrast with their present liberal and homely organisation. At a recent trial for murder by a lunatic in an asylum, a learned judge went so far as to suggest all this, seeming inclined to censure the asylum officers, because they had not kept all those lunatics in whom there was reason to suspect any dangerous propensities locked up in strong cells by themselves. The public, however, is not likely to adopt

this singular judicial view, nor to sanction what would be practically a return to barbarism in the treatment of a severely afflicted class of our fellow men.

The tendency is to emancipate the insane from the last vestiges of restraints, rather than to plunge them again into dungeons and fetters, and the advantages of the humane method of treatment in promoting recovery, and in securing tranquillity and comfort where recovery is out of the question, are so well known that no apprehension need be felt that they will be sacrificed to the clamour of timidity or ignorance. A price must be paid for freedom. Certain risks must be run in carrying out all great projects. These must be diminished as much as possible, but their existence need not cause any weak and cowardly halting on the path. The humane system of treatment of the insane has certainly its risks and dangers, to which not only lunatics themselves but those who have the charge of them are exposed. A Commissioner in Lunacy, a number of medical officers, attendants, and nurses have been killed at their posts, and about 6,000 asylum officers go about to-day cheerfully with their lives in their hands, applying the great principles of humanity in dealing with lunatics. They never think of calling these principles in question when one of their number falls a victim to their faulty application, or to the chances of the particular mode of life which they have chosen, and the public need not, therefore, call for radical changes and stringent measures whenever one lunatic is unhappily killed by another.

THE DUNDEE ROYAL ASYLUM.

THE severity of the weather during last winter caused considerable delay in the works at the new Dundee Asylum at Westgreen, but the buildings are now approaching completion, and it is hoped that they will be ready for occupation in the course of next month. The old asylum, which is to be abandoned, contained at the close of the Asylum year on the 20th of June last 290 patients, 114 males and 176 females. During the previous twelvemonths 126 patients were admitted, of whom Dr. Rorie says, that their physical condition on admission was very unsatisfactory. Of the 126 cases only 28 were found to be in really good bodily health; 43 were in a fair or indifferent condition; 35 were in a frail or very indifferent state; 6 were registered as very frail, or as frail and paralytic; 2 were suffering from long standing epilepsy, 2 from advanced heart disease; 1 had a fractured forearm, 1 a fractured ankle, and 1 had a severe and dangerous wound in the abdomen. Twenty of the patients admitted had, on one or more previous occasions, been inmates of the asylum.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 35, Bombay 26, Paris 27, Geneva 19, Amsterdam 21, Rotterdam 20, The Hague 24, Copenhagen 20, Stockholm 25, Christiansa 22, St. Petersburg 39, Berlin 21, Hamburg 21, Dresden 21, Breslau 22, Munich 26, Vienna 24, Prague 24, Buda-Pesth 29, Naples 25, Venice 32, Alexandria 41, New York 26, Brooklyn 22, Philadelphia 19, and Baltimore 26. No returns were received from Rome or Lisbon.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

(Continued.)

Mr. WHEELER read a paper on

THE OPERATION OF NERVE STRETCHING FOR TETANUS.

Which will be found on page 534.

Professor E. H. BENNETT thought the Society might congratulate Mr. Wheeler on his communication, and particularly on his success. [At the International Congress last summer, Professor Esmarch quoted five cases of traumatic tetanus in which he had stretched the nerves with deplorable failure. So far as Esmarch's experience went, the operation had produced no result. In quoting so well-known an authority, he did not in the least disparage Mr. Wheeler's laudable attempt to control tetanus, but with the view that they should have knowledge of the unfavourable cases as well as the favourable.

Professor STOKES joined with Professor Bennett in congratulating Mr. Wheeler on the result he had obtained; but he was surprised that Mr. Wheeler, who had evidently looked into the literature of the subject, had not mentioned either the cases of Esmarch, or those of Dr. Carl Langenbuch, who had published two cases of traumatic tetanus in which he had stretched the nerves. In both those cases, as in Professor Esmarch's, the result proved fatal. This fact should make the Society congratulate Mr. Wheeler the more on his success. As he (Professor Stokes) believed he was the first who performed the operation of nerve stretching in this country, he desired to mention a few facts connected with the case in which he had operated. It was not one of traumatic tetanus, but of *locomotor ataxy* in which the symptoms were well marked. Everything that the highest medical skill and science could do had been done for the patient, who was under the care of the most eminent physicians in the city, first in the Meath and subsequently in the Whitworth Hospital. The symptoms included lightning pains, great irritability of the bladder, night and day, necessitating his passing water almost every half-hour, and there was a want of muscular co-ordination. He exposed the sciatic nerve and stretched it, making the central tension greater than the peripheral. What was the result? No marked improvement in the patient's power of locomotion, but a cessation altogether of the pains from which he had acutely suffered, and for a considerable time also there was great relief from the vesical irritability. He would not discuss the theories respecting the *modus operandi* of the procedure, believing they were altogether in the dark as to how it acts; but it was certain from the experience they had had, that in many cases the operation of nerve-stretching was attended with beneficial results, and these in many instances not of a temporary, but permanent, character. In the case in which he had himself operated, the effect was temporary as regarded the vesical irritability, while from the great pains the patient had ever since enjoyed complete immunity. Owing to want of improvement in the patient's powers of locomotion, he did not deem it justifiable to perform the operation on the opposite side of the limb. He had mentioned the case as possessing features of clinical interest, and bearing to a certain extent on Mr. Wheeler's interesting communication.

Dr. ROBERT McDONNELL, while congratulating Mr. Wheeler on the success of his case, thought they should be extremely slow in drawing conclusions from single cases of the kind. They could not possibly draw a conclusion as to the success of the treatment in question until there was a much larger number of cases than had been yet recorded. The literature of the subject did not point to happy results; and before adopting an important innovation in surgical treatment for affections of the kind, they should carefully consider whether there was reasonable likelihood of its being successful. In other words, before they were justified in taking a knife to perform the operation, they ought to consider, first, whether it was not purely experimental, and next, whether it was an experiment justified by the facts and knowledge before them. While admitting freely that everything in medicine and surgery was tentative, and that it was their duty, especially in a case of so terrible a nature as tetanus, not to be too cautious, still, if there was anything

certain about the pathology of tetanus, it was this, that the spinal cord was very much affected in the cases that had become fatal. All pathologists agreed that the spinal cord was found of a distinctly pinkish colour. Even on examination of the spinal cord by the naked eye, it could be discerned. Dr. Lockhart Clarke from examination of men and the lower animals, had stated that the spinal cord in tetanus resembled the condition of poisoning by strychnine. It was difficult to see how the stretching of a nerve could produce any effect on an organic disease of the spinal cord, either in tetanus or *locomotor ataxy*, which was a more remarkable condition. If there was anything certain, it was that the posterior columns of the cord were in cases of *locomotor ataxy* completely disorganised. It was inconceivable how a disease which had advanced slowly until the nervous structure had disappeared, could be wiped out by the stretching of the sciatic or any other nerve, and he should be unwilling, in view of the facts, and on merely tentative grounds, to undertake an operation of the kind. There were two theories with regard to tetanus which were generally received: one that it was the result of nerve irritation, and the other that it was the result of a poison generated in the wound and producing toxæmia. If toxæmia, nerve-stretching could not cure it. On the other hand, assuming it was irritation, neuritis, the operation would be quite legitimate, it was possible, that by some unexplained process, the stretching of the nerve might produce counter irritation, and so stop the formidable effects produced. He did not attempt to explain it. There were many things it was difficult to explain; for instance, the action of a common blister, the physiological reason of which was inexplicable, but they did not doubt the effects. Though he would be chary about adopting nerve-stretching himself, in a case of tetanus, feeling that there was not sufficient likelihood of its doing much good, he looked with interest to those who, being bolder than himself, did not hesitate in performing the operation, and therefore he looked forward to other cases which would give firm data to go upon before drawing conclusions as to the curative effects of the operation.

Dr. HENRY KENNEDY mentioned, as bearing on the subject, that the late Dr. Colles, speaking of trismus in infants, had specified the application of turpentine to the umbilical cord as affording the only benefit he had seen. When a person got a wound which was followed by tetanus it was natural to attribute the tetanus to the wound. No matter how it extended to the spinal cord, the disease had its origin in the seat of the wound. Therefore, where the operation was done with little or no injury he would be inclined to follow out Mr. Wheeler's case. There were a number of cases in which general symptoms have been alleviated by such an operation as Mr. Stokes had described.

Mr. CORLEY having had rather unfortunate experience himself, listened with interest to learn if there were any improvement suggested in Mr. Wheeler's treatment. The statistics, which he had heard for the first time, showed one cure out of eight cases. Under his own care he had had sixteen cases of tetanus which had been treated in various ways. Of these, two recovered. He could not honestly attribute their recovery to the remedies used. Mr. Wheeler had said he was thinking of stretching the brachial plexus, and, if he had done so, he thought he would attributed the result to that. Suppose he had done nothing, what would have been the result?

Mr. HAMILTON had no doubt that if the tetanus was merely a local matter resulting from the effects of the wound or injury, such an operation as Mr. Wheeler had described would be exceedingly useful. Under similar conditions he would himself try the experiment; because, after all, he did not think it was a serious operation, especially in a disease of so deadly a nature. But from what he had seen and read, he had long held that tetanus was not merely a local disease. Looking carefully over the history of tetanus, it would be found to have occurred in epidemics. An epidemic of tetanus occurred in London when first the operation of tying hemorrhoids was introduced. Three or four terminated fatally. He remembered one year in which they had three cases of tetanus at Steeven's Hospital, and there were six in various hospitals in Dublin, a fact which made a forcible impression on his mind that there were some atmospheric influences at work which rendered tetanus liable to occur. There was a good deal to be learned

about tetanus, and they must not allow their attention to be concentrated altogether in one direction, but look to general causes as producing it.

Mr. WHEELER said he was aware of Prof. Esmarch's cases; but he had emphasised the words that he knew of only one case "well and fully reported"—Dr. Vogt's. Prof. Esmarch's were so epitomised that no conclusions of value could be drawn from them. Of the other case mentioned, he was not aware, nor did the speaker state where it was published. He had intended the discussion on his paper to be confined to nerve-stretching in tetanus, remarking that he could have related cases where he had stretched the supra-orbital, spinal-accessory, facial, and external popliteal nerve, and even others where the sciatic nerve was stretched in locomotor ataxy with results similar to what Dr. Stokes stated. He concurred with Dr. M'Donnell that if the affection commenced in the spinal cord (central) from poisonous effects nerve-stretching could not be of use; nor would one know what nerve to stretch. But he could not hold that an operation should be refused to a patient because it was a bold one that would give the sufferer a chance of recovery in acute traumatic tetanus, or because only a limited number of such operations happened to succeed. Dr. Corley had misunderstood what he had said in his communication. What he did say was, that had he stretched the brachial plexus; he believed the spasms might have stopped at once, as in Dr. Paul Vogt's case. Dr. Corley was also mistaken in saying there was only one successful case out of those recorded, his (Mr. Wheeler's) being a second. In the treatment of traumatic tetanus he himself had had two recoveries out of six or seven cases. Dr. Corley then asked what in Mr. Wheeler's opinion would have happened had he not stretched the nerve? He (Mr. Wheeler) had no hesitation in saying the child would have died. She had not got relief until after the nerve was stretched. In reference to Dr. Kennedy's remarks, he believed Venice turpentine was recommended to be applied to the funis of children suffering from trismus. No doubt vicissitudes of climate sometimes caused tetanus, but the observations of the two last speakers had no special reference to his case. In this operation he believed there was a numbing of the nerve which prevented impressions being carried up to the cord and thus the cord regained its normal state nerve centre, and control. This was a reasonable deduction when it was proved by Brown-Séquard that a nerve rubbed with ether would not transmit impression.

The discussion then closed, and the Society adjourned.

EDINBURGH OBSTETRICAL SOCIETY.

THIS Society held its third meeting on Wednesday, Dec. 14th, under the Presidency of Professor SIMPSON.

Dr. HALIDAY CROOM exhibited a "Malformed Fœtus," about the fifth month, the malformation consisting in the presence of two cysts on the back of the neck; they were symmetrical, not connected with the spinal cord, and evidently diurnal.

Prof. SIMPSON showed a bottle containing some fluid which had been drawn from a cyst on the anterior lip of the uterus, impeding labour. The fluid was removed with an aspirator, and the labour completed with the aid of forceps. The child was stillborn, but the mother is doing well.

Dr. CHAPMAN exhibited two fibroid tumours removed from the cervix uteri.

Dr. CROOM read a paper on

FUNIC HÆMORRHAGE DURING LABOUR.

After discussing that form which occurred through sudden delivery and rupture of the cord, in which hæmorrhage is always very slight, he went on to discuss, with illustrative cases, that form of funic hæmorrhage which arose during labour from a faulty insertion of the cord. He pointed out the rarity of the condition, and after disposing of the literature of the subject, went into a description of insertio-velamentosa, the condition usually associated with this form of hæmorrhage. He showed three sources. 1. Where the hæmorrhage comes from the funic vessels, passing over the lower segment of the membranes to a placenta normally situate. 2. Vessels inserted marginally into a placenta situate low down. 3. From vasa aberrantia. The diagnosis and treatment were discussed at length, the latter mainly consisting in the preservation of the membranes, and immediate delivery on their rupture.

Prof. SIMPSON, after thanking Dr. Croom for his interesting paper, stated that he had never met with a case of hæmorrhage from the cause noticed in Dr. Croom's paper, but that the possibility of such a complication rendered the communication most important.

Dr. PETER YOUNG had had three cases of velamentous insertion in the placenta of the cord, but in one only had the pulsations of the umbilical vessels been felt before delivery.

Dr. CROOM briefly replied.

Dr. KEILLER's "Report of the Royal Maternity and Simpson Memorial Hospital for the quarter ending August 1, 1881," was then read.

The reading of the report led to some desultory remarks by Dr. Craig, Dr. Croom, and others on the value of ergot in labour.

As the evening was far advanced, Prof. Simpson's paper on "A Case of Basilysis," was postponed to a future meeting of the Society.

OPHTHALMOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

W. BOWMAN, F.R.S., President, in the Chair,

Dr. MILES, of Manchester, showed a case of

GENERAL RETINAL PERIARTERITIS IN ONE EYE.

The patient was a man, æt. 59, suffering from chronic albuminuria and valvular disease of the heart. The arteries of the retina were all transformed into snow-white cylinders, capable of being traced to their third divisions. The exudation so nearly obliterated the red colour of the vessel that only the most minute inspection enabled one to determine the existence of a blood current here and there in the form of fine red dots. Extensive hæmorrhages were present in the retina. Vision was reduced to perception of light in the affected eye. The sight of the other eye was reduced.

Mr. R. J. PYE-SMITH (Sheffield), sent notes of a case of

ACUTE GLAUCOMA FOLLOWING CONCUSSION—CURED BY ESERINE.

On the fifth day after a fall downstairs, the left eye of a lady, æt. 70, became acutely glaucomatous (+ T. 2), vision reduced to counting fingers, cornea steamy, pupil dilated, coloured rings observed round a candle. The use of eserine discs entirely relieved all the symptoms within twelve hours. Very slight and transient relapses occurred for a year at intervals of not more than a month. They were always dispelled by the use of eserine discs, and latterly became less and less frequent till they seem to have finally ceased three months ago. The eye is now normal, and can read "brilliant" type (Jaeger 1) with the reading-glasses that have been used for several years.

Dr. BUZZARD related the case of a lady, æt. 64, seen by him some two or three years since; she had suffered for eight weeks from severe frontal neuralgic pain in both eyes, especially the left. He found great increase of tension in the globes, intense photophobia, pupils moderately dilated and immovable to light. A leech was applied to each temple in both eyes, and by Mr. Lawson's advice eserine discs were used two or three times a day. She rapidly recovered, and has had no relapse during twelve months.

Mr. BOWMAN thought this evidence of the value of eserine in some cases of glaucoma very important, as it seemed to indicate that it might be used in place of an operation.

Mr. A. CRITCHETT remarked that he had recently under his care a man with chronic glaucoma who was treated persistently with eserine, and his vision steadily got worse.

Dr. ANDREW (Shrewsbury) had seen great good from the use of eserine in eyes showing early signs of sympathetic irritation; in such cases at the same time as he excised the bad eye, or when this operation was delayed, he used eserine to the "sound eye." Where the iris was at all hazy he recommended occasionally testing for synechia by atropine.

Mr. MOHARDIE had noticed that while eserine might cure one or two attacks of glaucoma, it might prove quite useless in a subsequent relapse. He was therefore unwilling to trust it where he had not the patient constantly under observation. It was of great use where iridectomy had to be postponed, or as a preparatory step to that operation.

Mr. GEORGE CRITCHETT was doubtful of the permanent effects of eserine; while very useful for its temporary good effects, he would rather trust to iridectomy for actual cure;

he should not like to lose sight of a case that had been treated only by eserine.

Dr. GOWERS related the subsequent history of a young woman suffering from

CEREBRAL TUMOUR AND DOUBLE OPTIC NEURITIS.

shown last session. She is better, and the upward movement of the eyes has increased. The neuritis has slowly subsided into atrophy, with deterioration of vision, so that in March last sight was 1-15th, but now she can make out No. 2 test type. The discs are very pale, with much new tissue and narrowed vessels. The field of vision in one eye is normal; in the other restricted for white, blue, and yellow; very small, irregular, and different for green and red, with a scotoma for each colour above the fixing point. He thought an irregular alteration of the fields of this diverse character pathognomonic of consecutive atrophy.

Dr. GOWERS also related two cases of

CHOREA WITH OPTIC NEURITIS.

One was a boy, æt. 11, with "paralytic chorea" and distinct double neuritis, who gradually recovered and remained well. The second occurred in a man, æt. 20, whose chorea followed acute rheumatism, and who had a mitral systolic murmur, and no albuminuria; there was marked neuritis. He had examined a large number of cases of chorea, but had never before seen this condition, and there was only the case of Dr. Hughlings Jackson's recorded. Probably the two conditions were both the result of some common cause, and not consecutive.

Dr. BUZZARD remarked that he had never met with optic neuritis in chorea. He referred to the case of a young woman lately under his care with chorea who had developed symptoms of mania which ended in recovery, the crisis being marked by a crop of herpes about the mouth and tongue. He was disposed to attribute this outbreak of herpes to some basal meningitis, which had occasioned irritation of the fifth nerve within the cranium. A case of chorea which had presented similar mental disturbance was now in hospital, under the care of Dr. Radcliffe. In that patient also facial herpes had occurred. He suggested the possibility of the occasional occurrence of meningitis in chorea, explaining the association of optic neuritis. The latter patient's mental state had prevented ophthalmoscopic examination.

Dr. GOWERS replied, that in the younger of his patients there was no endocarditis, and the disease was so slight that he thought the occurrence of meningitis could be fairly excluded. One of the cases of chorea mentioned by Dr. Buzzard he had examined, and found to be free from neuritis.

Mr. C. E. FITZGERALD (Dublin) read a paper on

UNILATERAL EXOPHTHALMOS, AND THE VALUE OF THE SIGN DESCRIBED BY VON GRAEFE AS CHARACTERISTIC OF GRAVES' DISEASE.

The author's main object in this paper was to raise the question of the value to be attached to the interference with the consensus of the movement of the lid with that of the globe, especially when the latter is directed downwards. This is stated to be independent of the protrusion of the eyes, and even precedes it; it is often present in cases in which the position of the globe hardly exceeds physiological limits. The disease may, at all events at the outset, be unilateral. The author reported a case of well-marked one-sided exophthalmos in a young lady, aged seventeen; and of the true nature of this case there could be no doubt. Three other cases, however, which he recorded, appear open to question. The first was that of a young lady who consulted him for protrusion of the right eye and asthenopia. She was myopic in both eyes, and slightly astigmatic in the left. She had also well-marked insufficiency of the internal recti muscles. Glasses for distance and reading were prescribed, and gradually the protrusion subsided. About two years later she again consulted him, as the left eye had begun to protrude. She was seen by three physicians, who considered it was not a case of Graves' disease; but Mr. Liebreich, who also examined her, considered it an example of an incomplete form of this affection. She presented the effect already alluded to, and at one time a slight enlargement of the thyroid gland. The second case was that of a gentleman, aged twenty-eight, who had maculæ of both cornea, probably the result of an attack of phlyctenular keratitis some years previously, and well-marked exophthalmos of the left eye, which was myopic (-7 D). Two months before his visit he had an attack of erysipelas of the face; since then had observed a protrusion

of the left eye. No enlargement of the thyroid. Pulse normal; lid movement defect marked. The third case was that of a resident magistrate in a disturbed part of Ireland. He stated that about twelve months ago he had observed his right eye protruding forward. He had always enjoyed good health until about two years previously, when he was suddenly seized one day with a violent attack of what appeared to be colic, with retching. This passed off, but it was some time before he got quite well, and since that date he lost flesh. Latterly felt quite well. Observed that his eye always becomes more prominent after any excitement, smoking, or the use of stimulants. Had a great deal of anxiety during the present disturbed state of the country, and has had his life threatened. Pulsation of vena centralis retinae; no enlargement of the thyroid. Pulse normal. This gentleman has seen a well-known physician in Dublin who regarded it as a case of Graves' disease. He consulted Mr. Liebreich, who considered it the exophthalmos due to some affection of the orbit; defect of movement of lid well marked. The author quoted passages from Professor Sattler's monograph to show the importance attached to this sign, as shown by cases already published, where some of the other signs and symptoms were absent.

Mr. BOWMAN considered the failure of the lid to follow the movements of the eye as a very characteristic mark of Basedow's disease; it was not seen in other cases of protrusion of the eyeball, it appeared to be due to some interference with the action of the levator and orbicularis muscles.

Dr. GOWERS thought the absence of this symptom of small weight. He had known of a patient with cardiac mischief in which at death there was only a very slight degree of exophthalmos, and this strange effect on the eyeball was not seen at all. He had shown that in this disease, on attempting to look down, the eyelid does not fall over the eyeball, but on closing the eye it was easy to raise the lid.

Besides the papers read, there were several *card specimens* exhibited which attracted the attention of members. The society adjourned with the usual votes of thanks.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, DECEMBER 5TH.

Mr. THOMAS ARNOLD ROGERS, President, in the Chair.

AMONGST other "casual communications," Mr. W. E. HARDING, of Shrewsbury, related

A REMARKABLE CASE OF POISONING BY ARSENICAL PASTE.

A lady came to him complaining of acute pain in a lower molar. Finding the pulp exposed, Mr. Harding applied a small quantity of a preparation known as "Baldock's Nerve-killing Paste," closing the cavity with cotton-wool and sandarach. Within a few hours the patient was seized with symptoms of poisoning by arsenic—burning pain at the epigastrium, vomiting, and a rash resembling measles, but slightly raised. The stopping was at once removed, but the patient was very ill for several days, and did not altogether recover her health for a fortnight. A remarkable feature in the case was that this lady had suffered in the same way three times previously: once from arsenic used by another dentist, and twice from prescriptions containing it ordered by medical practitioners.

The PRESIDENT remarked that it was very important that patients who were the subject of such idiosyncrasias should mention them when they applied to a stranger for treatment, and any practitioner discovering such peculiarities should impress the necessity of doing this upon the patient.

The paper of the evening was by

Mr. A. COLEMAN, F.R.C.S., on

ECONOMICAL PROCESSES OF PREPARING AND ADMINISTERING NITROUS OXIDE GAS.

In proof of the importance of the subject to hospitals and large consumers, Mr. Coleman stated that the one item of nitrous oxide gas cost the Dental Hospital of London over £70 a year. After describing various ways in which the gas could be obtained, he said that he believed it could be manufactured on a large scale most cheaply by the action of dilute nitric acid on zinc. As a plan for making nitrous oxide alone, this method would be extravagant, since only about

one-third as much gas could be obtained by this means compared with that which could be obtained for the same money by the decomposition of nitrate of ammonia. But by treating the residual nitrate with sulphuric acid, the nitric acid could be recovered, and sulphate of zinc obtained, which was a well-known article of commerce. By making this the main object of the manufacture he believed that the gas could be obtained as a by-product at an almost nominal cost. Mr. Coleman then passed on to describe various devices for securing economy in administration. He hoped, however, that these might be superseded in large institutions by a plan for saving all the products of respiration during the administration of the gas, and then separating the latter for use over again. This might be effected by conducting the respired air and gas into a closed vessel containing a certain amount of water, in which a little caustic potash had been dissolved. This would fix the carbonic acid; the nitrous oxide would be absorbed by the water, and the remaining air might then be allowed to escape. Heat being applied, the gas would be driven off again from the water, and re-collected in another gasometer. The process was much facilitated by agitating the vessel containing the mixture of air, gas, and water, and by reducing the temperature of the latter as low as possible in the first instance. It would be attended with some expense, but might probably be found to pay in the case of large institutions, and where circumstances were favourable for its application.

Special.

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

SUCCESSFUL CASE OF THYROIDECTOMY.—M. Terrillon read a report at the Société de Chirurgie of a successful case of thyroidectomy. A woman, æt. 25, had a goitre for eleven years. For several years different remedies were tried without success, including puncture followed by injection of iodine, and application of caustics and drainage. She appeared cured for three or four years, but by degrees it returned, and she became subject to severe attacks of dyspnoea, and the voice was all but extinct. The tumour was half the size of the closed hand, and divided into three lobes. The skin was adherent, and a capillary puncture gave exit to a sanguineous liquid. The symptoms becoming rapidly worse, the operation was decided upon, and for that purpose an incision was made over the lower part of the tumour, comprising the skin which was dissected off the hypertrophied organ. The three lobes were successively ablated, hæmostatic forceps being applied to each large vessel as it was opened and then replaced by a ligature. The avulsion of the tumour terminated three drainage tubes were placed in the wound, which was partly closed by silver wire sutures. The operation lasted two hours. Reunion by first intention failed in many points, but, nevertheless, the patient made a good recovery.

PROLAPSE OF THE UTERUS.—M. Guéniot gave an account of five personal observations of prolapse of the uterus, treated by uniting the posterior and anterior walls of the vagina (*Cloisonnement*), by the operation practised by M. le Fort. M. Després considered that every operation made to restore the uterus to its position was useless, for the real cause of prolapse was the insufficiency of the perineum. The perineum is composed, not only of skin, but muscles, and it is to the weakness or insufficiency of these last that prolapsus is to be attributed. It suffices to make the patient cough to recognise this fact. M. le Fort could not accept this theory of M. Després, on the contrary, he considered that the perineum had nothing to do with prolapse of the uterus. M. Trelat was of the same opinion, and believed that the operation of M. Després (suture of the inferior third of the vulva) as worse than useless.

HYDRARTHROSE OF BOTH KNEES.—M. Nicaise presented a young man who was attacked with a double hydrarthrose of both knees, of four years duration, and on whom he had operated with success. M. Nicaise, after exhausting all the usual remedies, performed orthotomy, after which the articulation was washed out by an injection of dilute phenic acid, and a drainage tube was placed. On the nineteenth day the patient was cured. The opposite joint was submitted to a similar operation, and in fifteen days a like fortunate result was obtained. There was no articular stiffness left. M. Marc See regretted that M. Nicaise had not employed compression by means of the elastic bandage (Martin's), as he had seen it succeed where other means failed.

BROMISUS.—Dr. Lowy relates the case of a woman, who, being epileptic, took daily during her pregnancy thirty grains of

bromide of potassium. After her confinement the child was observed to be constantly sleeping, awaking but twice in the twenty-four hours. It rapidly got thin. At twenty days old he had the appearance of a little withered old man. The heart beat only eighty-six in the minute, the number of respirations did not exceed ten. The urine revealed traces of the salt. As soon as these phenomena were observed the child was seivered, and in a few days all the symptoms of bromism disappeared.

CARDIAC SYMPHYISIS.—A case of cardiac symphysis was observed recently at the Hôpital St. Andre, in a man who had succumbed to acute bronchitis. This individual was not rheumatic nor addicted to drink; he had a violent dyspnoea, but the heart was apparently healthy and without bruit. At the autopsy a complete cardiac symphysis was discovered, very thick, of cartilaginous consistence, and occupying the whole anterior surface of the organs. Hypertrophy was slight, but without valvular lesions. The aorta was slightly atheromatous, and the pericardium adhered to the neighbouring organs, and notably to the lung by false membranes.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, DECEMBER 21, 1881.

THE HARVEIAN LECTURES.

PRACTICAL gynæcologists will feel that Dr. Meadows has conferred a considerable obligation on them by the delivery of the Harveian lectures for 1881 on the subject of Menstruation and its Disorders. It is probable that, though there are several important points, both in theory and in practice, on which Dr. Meadows is not in agreement with a large proportion of his fellow workers in the field of gynæcology, his lectures will nevertheless be universally regarded as an able addition to the literature of the subject. We cannot here withhold from them the praise to which they are justly entitled, whether they may be regarded simply as a description of the derangements the menstrual function is subject to, or as a guide to the treatment to be adopted in such cases. Throughout the three discourses, Dr. Meadows successfully held the attention of his audience, and even in those places where he was compelled to assume a position of antagonism to the authority of other names, his words were received with the deference and approval that they are justly entitled to. It may not be, of course, that this is to be regarded as indicative of any

radical change in the opinions which have ruled the past, but it assuredly shows that enlightenment on subjects open to fresh demonstration is always eagerly sought and received; and we have much pleasure in congratulating both Dr. Meadows on the probable discussion that will be excited by his Harveian lectures, and the medical profession on the opportunities these lectures will afford of arriving at sound and safe conclusions on more than one moot point associated with the treatment of complaints peculiar to women.

The first of the three lectures delivered by Dr. Meadows was devoted to anatomical and physiological considerations. From the report of it already printed in the *Medical Press and Circular*, it will be seen that the points on which greatest stress was laid were those that gave functional importance to the ovaries. Pursuing a course somewhat unfamiliar to British ears, but concerning the justice of which there are probably few practitioners who would not agree with him, the lecturer insisted on the principal place occupied by the ovaries in the generative apparatus. In place of regarding these organs merely as appendages to the uterus, he declared them as being inferior to none of their surroundings in order of importance, and as being, in fact, the central point of the menstrual activity. This view is much more commonly accepted in America than it is here; but there can be no question that it is essentially correct, and that the majority of medical men will agree with Dr. Meadows in the opinion he thus expressed. We need not follow the mode of demonstration the lecturer pursued, except to say that it was based on anatomical grounds chiefly, the nervous and vascular supply to the ovary being, as Dr. Meadows urged, an ample proof of the dignified rôle pursued by the organ. It might almost be considered that unnecessary weight was attached to this demonstration, and we cannot but think Dr. Meadows imagines the principle he enunciated in this direction is less freely accepted than is the case. Our American contemporaries have, for some time, been discussing the importance of the ovary in the sexual act, and the result generally arrived at is favourable to its superiority over the uterus, &c., in point of functional power. The particular line of demonstration pursued by Dr. Meadows is certainly calculated to carry conviction with it, and we must not for a moment be supposed to express anything but admiration for the clear and excellent way in which he unfolded the truth he sought to deduce. We only venture to hint that he should be prepared to find a very considerable number of his professional brethren quite prepared to go with him the full length of his discoveries and conclusions.

The distribution of the nervous elements that go to the ovaries and uterus and associated organs, is perhaps the most interesting branch of this subject, from the clinical bearings it possesses. Dr. Meadows was particularly clear in his descriptions of the plexuses and their connections; and those who follow his lecture will have little difficulty in future, in comprehending the significance attaching to the variations in position and degree of pain originating either in the ovary or its appendage, the uterus. From the clinical standpoint this probably is the most deeply interesting of all the

anatomical details of the subject, and it is that, too, on which Dr. Meadows dwelt at most considerable length, while his conclusions as to treatment based on it were complete and admirable.

Lecture II. dwelt almost entirely on amenorrhœa, menorrhagia, and metrorrhagia, with the conditions giving rise to these disorders, and the most appropriate treatment of them. Those forms of amenorrhœa which are to be regarded as hopeless of cure, were shown to be such as are associated with ovarian deficiency, and as a detail of clinical significance must be regarded as the mode in which the diminished flow is brought about. In every instance where the cessation is attributable to blood poisoning, we are to expect no restoration of function, since the conditions set up are such as to produce changes in the ovary, with which ovulation will be utterly impossible. In all cases of this kind, moreover, sudden cessation of the menstrual discharge is a distinguishing symptom, whereas in those examples of slowly progressing ovarian atrophy, from the treatment of which benefit may be anticipated, the first recognised sign of disturbance is a gradual falling off in the amount and duration of the periodical discharge. The question of treatment here comes in, and Dr. Meadows' experience leads him to place but little reliance on drugs merely, his best results having been achieved by means of electricity and galvanism directly applied to stimulate the ovary to action.

Menorrhagia and metrorrhagia naturally occupied a considerable amount of attention, and the conclusions to which Dr. Meadows' ripe experience has conducted him concerning these conditions, will be read with very general interest. It is, perhaps, more than usually comforting to observe the frank outspoken contempt of mere druggists' treatment, in which such faith has formerly been reposed. The scientific study of signs afforded in these cases of deranged menstruation, conclusively shows the little influence that ordinary remedies exert upon them, but we imagine most readers of Dr. Meadows' lectures will thank him, where they do not already agree with him, for the hint as to employing the bromide of potassium for promoting ovarian quiescence. Nor will there, we suspect, be found any to disagree with Dr. Meadows respecting the mode of action of the bromide. It is assuredly a sedative by direct action on the ovarian nerve supply, and hence the value of it in checking the over-activity of the organ. Similarly good counsel is the advice to employ local anodynes to ease excessive pain, for it may be surely accepted as true that, in the absence of physiological rest, no organ can progress towards recovery when deranged.

We have not space to dwell as we would wish on each point of interest or importance, as it occurred, in these lectures, otherwise we might discuss the question of uterine tumours, on which Dr. Meadows dwelt at some length, in connection with menorrhagia, and on the diagnosis of which he offered valuable suggestions. His third lecture was chiefly devoted to dysmenorrhœa, its varieties and treatment, and under each division much valuable information was afforded. Naturally the association between difficult menstruation and flexions of

the uterus offered a field for the discussion of theories of treatment, and in this connection Dr. Meadows expressed his inability to endorse Dr. Graily Hewitt's explanation of the so-called strangulated condition of the womb, or the treatment of it by mechanical means, based on what Dr. Meadows regards as erroneous views. He insists that Dr. Hewitt's analogy between the flexed uterus and the bandaged arm is wholly false, since the venous blood returns from the uterus by *two* paths, a point dwelt on in the first lecture. Hence even when flexed on itself, no venous strangulation of the uterus can result, and hence also such treatment as is based on the assumption must likewise be ill-founded. On this point we may look for further discussion, and we trust it may be excited, in the interest of this branch of medicine. Of course, Dr. Meadows insists that treatment by a simple pessary in these cases is useless, and that a stem, such as his glass stem, will alone lend efficient support to the organ, the restoration of which he declares is but little aided by the mere assistance *by* support.

Regarded from every point of view, the Harveian lectures of 1881 are a valuable addition to the medical literature of the age, and on the special subject of menstruation and its disorders, they will doubtless become a starting point of future further advances.

THE ENTRIES OF STUDENTS AT IRISH MEDICAL SCHOOLS.

WE have received from Dr. Brady, the Inspector of Anatomy, the following statement of the number of students in anatomy returned to him by the various Dublin schools as having entered their names for the current year :

Trinity College	216
College of Surgeons	140
Carmichael School	159
Ledwich School	221
Catholic School	100
Total, Dublin Schools				836

We understand also that the class at Belfast College is very nearly 350—not much less than half the number of students entered at all the Dublin schools put together. We commend this interesting fact to the teachers of the Irish metropolis and to the administrators of Irish colleges for their most careful and speedy consideration. Belfast Medical School began at zero twenty years ago—steadily and surely it has gained ground (as far as the number of its students is concerned)—and has advanced foot by foot, until to-day its school greatly out-tops, in this respect, any school in Dublin. But Belfast and the other Queen's colleges of Cork and Galway are provincial, and as medical teaching centres they labour under all the difficulties of provincialism, the chief of these disabilities being the limited extent and insufficiency of their hospital teaching. Why then this numerical success? Some of it, no doubt, in the case of Belfast, is due to the reputation and the zealous indefatigability of Professor Redfern, its chief professor, but the greater part to the cheapness of the education obtainable in the

Queen's colleges, and the low price of the diplomas of the Scotch Corporations. In Dublin the teachers are engaged in the practical vivisection of "the goose with the golden egg," and have combined to prevent the Irish metropolis from competing with its provincial sisters for the patronage of the Irish medical student. They insist on the Dublin colleges requiring three courses of lectures in the leading subjects of the curriculum, while Edinburgh and Belfast only ask for one such course. It is only a few weeks since the Dublin teachers held a caucus and agreed together to charge nine guineas for the courses of instruction which can be had nearly, if not quite as well, in the Queen's colleges for two guineas. Furthermore these teachers uphold the charge of forty guineas for a Dublin diploma when an article of the same legal value can be had in Scotland by the Belfast student for fifteen guineas *plus* the return ticket fare to Glasgow or Edinburgh.

The Dublin teachers are, in fact, forcing the Irish double diploma to be sold at a cost of £150 odd—where its Scotch analogue can be had, *viâ* Belfast, Cork, or Galway, for a little over £60. Is it any wonder that—to use a commercial phrase—most buyers are seeking the cheaper markets? and, how long do the Dublin teachers calculate that the Dublin School can survive such treatment? Probably, we may be told "It will last for our time," but possibly even this limited aspiration may not be realised, and that the present occupants of professorships in Dublin may experience in each succeeding year the decadence of class and of fee income which is foreshadowed in the return given above.

This is not a question, however, to be settled without a word said on behalf of the Irish Licensing Corporations whose position as the nursing mothers of the profession in Ireland is being gradually sacrificed to the greed for multiple lectures and excessive diploma fees. The Irish Colleges of Physicians and Surgeons have already—we assert—lost their full grasp of the Irish student, and they retain barely enough hold upon him to make it possible, by immediate and sweeping reforms, to draw him back to their portals. For years past surgical and medical licensing in Ireland has been gradually falling away from the institutions, and—at the present moment—they are threatened with a competition on the part of the Royal Irish University which cannot fail to injure them vitally, if not to destroy them utterly. For such result the teachers would care little, so long as there were students to be educated for other licensing institutions, and there is therefore no reason why the colleges in question should submit to be starved out of existence by the all-absorbing greed of these functionaries. Let it be kept in mind that a wholesale cutting down of the bloated curriculum, now required by the Dublin colleges, would not, in the least degree, imply a depreciation of the educational standard heretofore maintained by them. Let it be recollected that reiterated courses of lectures and repeated fees do not indicate—do not even pretend to imply—a higher degree of education. Let it be kept in view that the monstrous course of sham study now ordered by these colleges might, at any moment, be curtailed to half its dimensions without the least injury to anyone but a few three-course teachers, and, bearing these facts in mind, it will be un-

derstood with what earnestness we urge Irish medico-educational reformers to the consideration of the figures which we have quoted, and to activity in saving the Dublin Medical School from the danger of dissolution which we apprehend.

The foregoing comments upon the returns of anatomical *entrants* at the Dublin schools have their foundation upon the falling off in the Dublin School and the rapid progress of that of Belfast, which circumstance can be neither denied nor explained, except by the reasons we have given. We ought not, however, to pass from the discussion of these returns without pointing out how utterly untruthful they may be, and have been, as a measure of the success or *prestige* of a particular school. In London each medical school records the actual number of students entered therein for the session. In Dublin nothing is allowed to transpire except the number of students who are said to enter in each year for dissections, and this becomes known only because the inspector of anatomy requires the information for the purpose of providing a sufficiency of subjects. Each school contributes one delegate to form what is called the "anatomical committee," and that body receives the returns of dissectors, sends the numbers to the inspector, and makes all other arrangements. Each school pays to the committee a guinea for each student returned by it, and the inspector is expected to supply one *cadaver* for each two dissectors. Under this system the returns could indicate at best only the number of dissectors entered at the various schools, omitting those students who have not begun, or else have concluded, their anatomical work. But the returns are illusory and unreliable in a much larger sense than this. It is said to have been the habit of certain schools to send in to the committee a much larger statement of their class than was really true, and they were believed to have done this for two purposes. First, they wished to look well in presence of the delegates of rival schools, and, with this object, they placed on their list every student they could possibly claim, no matter how hopelessly chronic he might be. Thus, certain pupils did duty as dissectors for, sometimes, seven to ten consecutive years. Secondly, these schools desired to obtain a plentiful supply of subjects which, always scarce, are apportioned to the schools in ratio of the size of their dissection classes.

It is true that they were obliged to lodge one guinea for each student included in their returns, but, as a rebate is always made at the end of the session, for all those subjects which the school did not require or receive, they got the money back again and lost nothing but the interest of a small sum for six months.

So much for these anatomical returns. As we have observed that they have been accepted and argued from by some of our contemporaries as an official measure of the relative strength of Dublin schools, we have thought it well to explain that, as such, they are unworthy of credit, and, at the same time, to expose one of the evolutions which the managers of certain Dublin schools have performed annually for years past in order to deceive the public as to their educational status.

THE MEDICO-SANITARY EXHIBITION AWARDS.

WE are induced to revert to this unpleasant subject in consequence of receiving from the Honorary Secretary of the Parkes' Museum of Hygiene a copy of the "Certificate of Awards," with a request that we should express an opinion upon its merits. As an artistic design it is eminently satisfactory, albeit the use of light and shade are not by any means such as could be seen in Nature. However, it is not with its artistic merits we are concerned, but we are reminded by the faulty shading of the certificate, that the process pursued by the judges in the Drug Section of the late Exhibition is also of a decidedly shady description; and we exceedingly regret to learn that it has been finally determined not to review the awards, concerning which we first put forth a protest.

We ventured at the time when we drew the attention of the profession to the improper awards made at the Exhibition, to point out the utter worthlessness of any made in association with those of which complaint is so justly made. The unanimous way, too, in which the whole medical press followed us, and endorsed the opinion to which we gave utterance, was then taken very generally as an assurance that the subject demanded careful reconsideration. The feeling experienced in regard to these adjudications, moreover, was one of such strength and universality, that it was impossible to imagine they would be for a moment sustained when such decided expressions concerning them had been pronounced. All the more surprise therefore, will be created by the fact that it has been decided by the Committee that the glaring inconsistency of the judges cannot be gone into; the exhibitors, therefore, who are justly entitled to demand at least an explanation of the treatment they have received, are afforded not even this to account for such extraordinary conduct. We do not intend to enter again at length into the particulars of the *modus operandi* which so unfavourably marked the judges of the drugs exhibited in Section 7. It will be enough to remind our readers that the awards included some to certain secret preparations, articles it is now admitted ought never to have been in the Exhibition at all, and which received high commendation from the judges, while the preparations of several of the best-known firms of chemists were passed by in absolute silence. It would have been supposed that such serious errors of judgment would have needed only to be pointed out to ensure a remedy; and we admit to a feeling of this kind when we decided to take on ourselves the duty of acquainting the profession with what had occurred. On the contrary, however, it would almost appear as though conviction of the inappropriateness of their awards has but intensified the determination of the judges to persist in upholding them, for the only reply vouchsafed to inquiries whether the decisions are at all likely to be reviewed, are met by the explanation that they are "final." We are thus presented with a curious spectacle that will probably possess features of interest for contemporary moralists.

We have first a body of highly intelligent and deservedly eminent scientific men conferring the distinctions of their approval on articles of unknown composition, and of the most unblushing quack descriptions. Next we have these same gentlemen refusing to acknowledge the existence of any merit in preparations by firms of worldwide renown, and of definitely known constitution. To these must be added the fact that these same gentlemen collectively or individually admit the preposterous nature of the pretensions put forth on behalf of the unknown remedies already approved by them, and further acknowledge that they were entirely unfit to be classed among the exhibits. Lastly, we have this same body of gentlemen arbitrarily refusing to undo any portion of that which not only is a glaring injustice, but is tacitly accepted by themselves in this very light. After this the question may well be asked, what possible value can be attached to the awards of the jurors; or, at any rate, of those to whom fell the task of adjudicating on the drug exhibits?

That certain well known English and American firms, and notably the latter, have been most unfairly treated in this matter, has been unanimously declared throughout the profession; and it may be, that this is itself an infinitely greater reward of merit than any that could have been bestowed by the judges. This, however, does not in any way remove the undesirable impression created by the action of these gentlemen, and especially by the obstinate determination they evince to stand by the decisions they have pronounced.

There is one other point on which we must for a moment dwell, and it is of considerable significance. The awards of the judges at all exhibitions like the one in question are recorded on certificates which, thenceforth, are rightly regarded by their possessors as testimonials of no little value. Also the ceremony of presenting these certificates and the other prizes awarded with them is usually the most interesting, as it is the final one connected with the exhibition. Certificates, it is true, have been prepared for distribution to successful exhibitors at the recent medico-sanitary exhibition, but no public ceremony has marked their receipt by those to whom they have been given; and this, we regard as the most conclusive evidence yet offered that the success of the exhibition has undergone some serious blow. We do not care to pay attention to the rumours which declared no person of eminence would consent to preside at such a meeting, nor to the reports circulated with equal freedom to the effect that the executive dreaded an outbreak of inevitable disapproval. It remains only to chronicle the fact that no meeting has been held, and that each exhibitor entitled to a certificate or prize by the judges' award, has received it through private delivery.

It will be a little curious to watch the effect produced by these certificates by and by. In many cases, of course, they will truly and rightly be regarded as honourable distinctions, but we do not hesitate to prophecy that no possessor of an award in Section 7, will long care, to herald the fact to the world, seeing that he would thereby declare himself as associated with successful exhibitors of avowed secret nostrums.

Notes on Current Topics.

Torture in the United States.

In the first number of the *Century Magazine*, Scribner's new monthly, it comes out incidentally in the course of "a curious experience" related by Mark Twain, that torture was used by an officer of the Northern Army in the examination of a supposed spy during the war of Secession. "A Curious Experience" is the picturesquely-told story of what befel a Major of the Northern army when Commandant of Fort Turnbull at New London, Connecticut, in dealing with a boy whom he had befriended from pity, whose singular proceedings led to his being regarded as a traitor in the camp, and a secret emissary of the Confederates engaged in dangerous practices, but who ultimately turned out to be only a romantic and ingenious little trickster, who was playing the spy for his own amusement and to gratify a morbid appetite for the mysterious, whetted by the study of lurid and sensational literature. At the time when he was actually believed to be a spy, and when disclosures as to the plans of the enemy was being extorted from him he suddenly broke off in his confessions, and then the Major goes on as follows:—"Neither coaxing nor threats had any effect on him. Time was flying—it was necessary to institute sharp measures. *So I triced him up a-tip-toe by the thumbs.* (The italics are ours.) As the pain increased it wrung screams from him which were almost more than I could bear, but I held my ground and pretty soon he shrieked out, &c., &c." A little further on we are informed that the boy again halted in his narrative, upon which, says the Major, "I tied him up by the thumbs again. When the agony was full upon him, it was heart-breaking to hear the poor thing's shrieks, but we got nothing else out of him. To every question he screamed the same reply 'I can die, and I will die; but I will never tell.'"

Now, the Major's history of his curious experience may be an artistic description of a real occurrence, or a piece of pure invention. Every effort is made to induce us to believe that it is the former, for a note is appended to it to the effect that the manuscript has been submitted to the Major, who says after reading it, "You have got the main facts of the history right and have set them down just as they occurred," an assurance which leaves us no choice but to believe that under the Major's command a boy was subjected to cruel torture. But if, on the other hand, the whole tale is a product of Mark Twain's fertile and intricate fancy, then it is singular that he should have introduced into it, when he was labouring to give it an air of probability, an incident that could not, by any possibility, have happened. If torture never was employed by officers of the Federal army in the interrogation of supposed spies, how comes it that this gifted author, without a word of apology or explanation, makes it a part of the machinery of his story? The point certainly requires elucidation, and at this moment when the great Western Republic is contending for the control of the Panama Canal, in case of war it is important to inquire whether there is the faintest ground for believing that any of her officers are capable of forgetting the usages of modern warfare, and of condescending to practices that remind one of the infamous Lopez in the worst days of Paraguay.

The Dangers of Electricity.

THE accident by which a labourer, on the Marquis of Salisbury's estate at Hatfield has come by his death, will very probably be taken to indicate the excessive dangers associated with electricity as a means of illuminating. This, however, it is to be hoped, will not be allowed to influence the arrangements whereby the new light is being rapidly introduced into general use; but, at the same time, it ought to serve as a warning against the commission of errors such as that to which the death of the unfortunate man was due. It should always be remembered that a current of electricity of power sufficient to afford lighting power of any dimensions, is at the same time a fearful engine of death if, by any mischance, it should be brought into contact with a human, or, indeed, any living body. Hence, a first duty to be discharged in connection with the new illuminant is at all times to secure chance passers by from harm by effectually insulating the conducting wires. Had this been done at Hatfield there would have been no accident to chronicle, and no distrust excited against a force which exhibits itself in so terrible a fashion.

As the facilities for employing the electric light become further developed we must expect to witness its almost unlimited adoption, and in proportion as its use increases, so also will the dangers attendant on it multiply until they are efficiently guarded against. The more particular, and the more quickly these are sought, then the more confidently will the people regard electricity and admit it into general employment.

Health Congress at Brighton.

DURING last week an important series of meetings have been held at Brighton, in connection with the Health Congress which has been in session in that place. The work done by the Congress has been of service rather in the way of suggestion than in that of actual performance. But it will most certainly be productive of good if only by leading to circulation of the admirable addresses delivered by Dr. B. W. Richardson, Dr. Alfred Carpenter, Mr. Edwin Chadwick, and Mr. Brudenell Carter. This last-named gentleman addressed an audience, at an evening meeting, on "Eyesight;" and in the papers read at the ordinary meetings of the Congress, such subjects as "Domestic Health," "Educational Training," "Sewage," &c., &c., found a place. The attractions of the Congress were enhanced by an exhibition of sanitary objects, held under its auspices. Both this and the general meetings and lectures have been fairly well attended by the general public; and the Congress is pronounced by its originators to have been successful throughout.

THE annual rates of mortality last week in the large towns of the United Kingdom per 1,000 of their population were, in—Wolverhampton 13, Norwich 14, Plymouth 15, Brighton 15, Portsmouth 17, Bristol 18, Sunderland 18, Birmingham 18, Bradford 20, London 20, Edinburgh 20, Sheffield 21, Salford 21, Manchester 21, Newcastle-on-Tyne 22, Glasgow 22, Leicester 22, Leeds 23, Oldham 24, Nottingham 24, Liverpool 26, Dublin 28, and Hull 33.

A Curious Sequel to Suicide.

THE Plymouth papers report a somewhat interesting case of suicide, which presents certain features to make it worthy of being remembered. The would-be victim—a young woman—swallowed two threepenny packets of rat poison, containing a considerable proportion of nux vomica in its composition. Soon afterwards attention was drawn to the suicide, and medical aid sought on her behalf. She was found in a tetanic condition by Dr. Pearse, who, in company with Dr. Miller, then treated her with a view to expelling the poison swallowed, and the nature of which was abundantly clear. The spasms, however, prevented any effectual treatment by ordinary means, and subcutaneous injection of morphia was resorted to. This would appear to have been attended with the most beneficial consequences, for the newspaper report proceeds: "After one spasm, both breathing and pulse having ceased, she was pronounced dead; but, to the surprise of those about her, she recovered both her pulse and consciousness, and the usual treatment being followed up, she gradually came to herself." The case is interesting in several respects, but especially as showing the power thus exerted over the tetanus of strychnia poisoning by means of morphia injected directly into the circulation.

The Wimbledon Mystery.

THE death of a scholar in a school at Wimbledon, and the circumstances surrounding it, have excited a painful interest in the medical profession, from the prominent position occupied by one of its own members in connection with the affair. Mr. Lamson, who is the holder of more than one medical qualification, having voluntarily presented himself at Scotland Yard to testify concerning the last interview he had with the unfortunate deceased, was forthwith arrested by the authorities, and himself charged with committing the deed. Into the merits of the case we do not, of course, for a moment propose to enter at present; but we may be allowed to express the regret we cannot but feel that this imputation of disgrace should be added just now to another blow recently sustained by the profession of medicine.

Patent-Medicine Revenue Fraud.

AT the Central Criminal Court, recently, a woman named Lewis, was indicted, together with Walter Stafford, an agent, for having in their possession parts of stamps which had been fraudulently mutilated. It was alleged on the part of the Inland Revenue authorities, the prosecutors, that they had been defrauded by the defendants of a considerable sum of money by means of an ingenious system of fraud in connection with the mutilation of the Government stamps. The defendants seemed to have carried on the business of selling patent medicines. They dealt principally in two patent medicines, which were described as being essence and syrup of phosphorus. These they sold in bottles priced 2s. 6d. and 4s. The regulations of the Inland Revenue Department provide that a stamp of 3d. must be affixed to each 2s. 6d. bottle, and the charge against the defendants was that they had cut the stamps in half, and by a peculiar and ingenious manner of placing the wrapper on the bottle the half stamp was made to appear as an entire one, one stamp being made to do duty for

two. The defendants denied the charge and urged in defence that the fraud had been committed by a man who had formerly been employed by the female defendant as a messenger, and that they were entirely ignorant and innocent of the matter. The jury acquitted the accused, who were accordingly discharged.

The Notification of Infectious Diseases in Edinburgh.

IT seems that the recent prosecution of Dr. Bowie for not concurring with the sanitary policeman in his diagnosis of typhoid fever is not likely to rest where the decision of the Sheriff left off. The subject of the working of the notification system is to be brought under the special notice of the Town Council. Meanwhile, a meeting was held last week in the Waverley Hall, for the purpose of discussing the present mode of administering the notification law in Edinburgh. Dr. Bowie, whose case has been fully reported and commented upon in the *Medical Press and Circular*, addressed the meeting. Dr. Bowie's letter, which we print to-day puts on the transaction an entirely different complexion. The diagnosis of infectious diseases, before they were fully developed, is one of the most delicate duties of a physician, and it is preposterous that the official connected with the health department of the city should entrust that duty to an ex-policeman. Dr. Bowie does not "regret having been made the first victim of the section, because it afforded the public an opportunity of seeing how the Act was carried out, and how unjustly it pressed upon the profession."

False Certificates of Death.

WE are pleased to chronicle the fact, that a few days since, Mr. P. J. Kendrick, M.R.C.S.Eng., residing at 9 Tavistock Square, London, who keeps a branch dispensary, which is managed by an unqualified assistant, was summoned by the Medical Defence Association, and fined £10, and £2 2s. costs, for signing a certificate of death in the case of a child which he had not seen, but which had been attended by his unqualified assistant. A few such wholesome lessons as this will go a long way towards stopping that outrage to the profession, and the public "the unqualified assistant system."

A Surgeon Poisoned by Prussic Acid.

AT Writtle, Chelmsford, last week, an inquest was held on Nathaniel Barlow, 64, surgeon. The deceased suffered from internal pains, and had recently taken small doses of chlorodyne. On Thursday he suggested to a brother practitioner that a little prussic acid might afford more relief. He was advised that his heart was too weak for this remedy, but he took it on being left alone, and died in a few seconds. The jury returned a verdict of "Death from inadvertence."

A BUST of Dr. Protheroe Smith, the founder of the Hospital for Women, Soho Square, London, the first of its speciality, was recently presented to the Institution by friends and patients, and was unveiled, on Thursday last, by Sir Rutherford Alcock, K.C.B., the Chairman of the Committee of Management, in the hall of the Hospital.

The Anti-Vivisection Prosecution.

At a meeting of the Harveian Society, on November 17th, the following resolution, proposed by Dr. Broadbent, and seconded by Dr. Cavafy, was passed unanimously:— "That the Harveian Society of London tender a very hearty vote of congratulation to Dr. Ferrier on the happy result of the fanatical prosecution to which he has been subjected."

Female Guardians.

An influential meeting has been held at Leeds, under the presidency of the Mayor, to consider the advisability of promoting the election of a certain number of ladies to serve on the Leeds Board of Guardians, which body has just adopted the triennial system of election. A resolution in favour of female guardians was unanimously carried, and two or more lady candidates will be selected for the election in April next.

A Medical Scandal at Birmingham.

A SERIES of charges, gravely reflecting on the conduct of Dr. Simpson, Senior Medical Officer to the Birmingham Workhouse, have been made by the guardians to the Local Government Board. It is alleged that patients have been systematically subject to blistering, shower-baths, and other extreme modes of treatment, simply as "punishment;" and, naturally enough, the assertion has excited strong indignation against the authors of the system. It seems that such proceedings have been continued for some time, and at length the abuse has become so excessive that the attention of the guardians has been compelled to it. This body, after an exciting discussion, has resolved to apply to the Local Government Board to hold an inquiry into the whole matter.

The Sunderland Conspiracy Case.

A MUCH respected member of the profession writes that there appears to be a desire in some quarters to misrepresent the Sunderland case of conspiracy. It is only fair to say that the learned Counsel for the accused, Mr. Strachan, gave an emphatic denial to the statements which appeared in the columns of a contemporary last week, and that the local public have sufficiently interested themselves in the matter to call a meeting in the Assembly Rooms for the purpose of forming a defence fund to defray the expenses of the ensuing trial. As the case is now remitted to the assizes, and will probably be tried before a special jury, our correspondent need have no fear lest justice should not be done; and we are quite sure that the profession and the public will suspend their judgment on the whole case until it is fairly stated and decided. However careful reporters and editors may be it is often difficult to avoid showing an apparent bias in publishing necessary reports of cases *sub judice*, but this is seldom in the end the cause of injury to any party in the case.

DR. WILLIAM SMYTH, M.B., of Banbridge, has been appointed by the Lord Chancellor of Ireland a Justice of the Peace for co. Down.

THE library of the late Dr. McClintock which is

especially rich in obstetric and gynecological works will be sold by auction at Jone's sale rooms in Dublin, on the 28th and following days.

WE regret to announce the death on November 14th, of Surgeon H. L. Cox, Army Medical Department, at Dilkosha, Lucknow, East Indies. Dr. Cox entered the army in April, 1880, and after passing through the Netley course proceeded to Bengal for a tour of duty. He fell a victim to cholera, of which there had been a few sporadic cases amongst the troops.

IN the large towns last week the highest death-rates per 1,000 from scarlet fever were 12.1 in Hull, 2.8 in Nottingham, 1.8 in Sunderland, and 1.7 in Leicester; from measles, 3.2 in Leeds, and 3.1 in Liverpool; and from "fever" (principally enteric), 2.8 in Oldham, and 1.4 in Plymouth. In Hull 36 more fatal cases of scarlet fever were recorded, raising the numbers registered since the beginning of July to 561. The 56 deaths from diphtheria included 25 in London, 10 in Glasgow, 9 in Portsmouth, 4 in Edinburgh, and 2 in Leicester. Small-pox caused 25 more deaths in London, 2 in Nottingham, but none elsewhere.

WE consider it our duty to reproduce the following notice from the *Journal of the Society of Arts*:—"It having come to the knowledge of the Secretary that circulars, purporting to be issued by 'The Society of Science, Letters, and Art, of London,' or some similar title, and dated from Finsbury Park or Upper Tollington Park, have been sent to certain Members of the Society of Arts, inviting them to subscribe to the 'Society of Science, Letters, and Art,' and that several subscriptions have been paid to the Secretary of the above Institution under the impression that it was connected with the Society of Arts, he is desired to give notice that nothing whatever is known of such a Society at this office, and that it is not associated in any way with the Society of Arts."

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

NEW REGULATIONS FOR EXTRA-MURAL LECTURES IN EDINBURGH.—The following regulations regarding the recognition of courses of instruction given by extra-academical lecturers, as qualifying for graduation in medicine in the University were adopted at a meeting held last week:—"Every applicant for recognition shall furnish for the information of the authorities of the University:—1, A syllabus of his course of lectures; 2, a statement of the number of lectures, and of the number of written or oral examinations in the course; 3, a statement of his opportunities of studying the subject in which he desires recognition, and of the length of time devoted thereto; 4, a statement of the experience he has had in teaching the subject; 5, a note of the titles of his contributions to the science of the subject; 6, a statement as to whether his course or courses of instruction have been already recognised by any University or other examining body, and if so, what means were adopted for ascertaining his qualifications for teaching. In the case of every applicant for recognition residing in Edinburgh or its neighbourhood, an inspection shall be made of his teaching

appliances and accommodation for teaching. Every recognised extra-academical lecturer shall annually furnish the University with the information regarding his course or courses which is required from the University Professors as to—(1) The number of students attending the recognised course or courses of instruction; (2) the number of meetings for ordinary class work in the session, and in each week, thereof, excluding meetings which fall under the next head; (3) the number of special written examinations; (4) the system of conducting the ordinary class work, and the number of meetings devoted to each kind of work. In the event of an extra-academical lecturer removing from the premises or building occupied by him for teaching a recognised course, such lecturer shall be required to intimate his removal to the University Court, in order that the Court may have an opportunity of considering whether the accommodation in the building to which he has removed is adapted for the purpose of teaching the subject in which he was recognised. When application is made for the recognition of a course taught by two or more lecturers in conjunction, information shall be given of the share to be taken by each lecturer in such a conjoined course; and the recognition of such conjoined courses, and of each of the lecturers recognised as teachers of a conjoined course, shall, *ipso facto* terminate, should one or more of the lecturers cease to conduct the course, or should any material change be made in the share of each lecturer in the teaching of the conjoined course. The recognition of any lecturer who has ceased for the period of two consecutive sessions to teach the subject on which he was recognised shall, *ipso facto*, terminate."

"HEALTHY WOMANHOOD."—Dr. W. L. Reid's lecture on this subject, delivered recently under the auspices of "The Combe Trust," has been published, and is being sold throughout Glasgow at the very moderate cost of one penny. The purchaser is, of course, left to determine whether he gets value for his money. Prior to its delivery this lecture was extensively advertised, and it was intimated that only females would be admitted to hear it. Curiosity thus whetted after the manner of sign-boards, which announce "Please don't read the other side of this board," the lecture is published as above indicated. We say in the fullest personal friendliness to Dr. Reid that we very gravely question the public benefit likely to accrue from the indiscriminate publication of a penny pamphlet detailing so much of a delicate and essentially professional nature regarding the female sexual organisation. We understand the pamphlet is bought largely by young men, and through the pushing of "The Christian Institute." The association of religious fervour and sensual proclivities have been long noted. We have no hesitation in saying that we consider the publication of this pamphlet, in this manner, an ill-advised act.

GLASGOW UNIVERSITY AUTHORITIES AND THE STUDENTS.—In consequence of the recent unseemly demonstrations by the students of the University of Glasgow at the Gaiety Theatre, the Senate has issued a notice, in which they condemn the behaviour of certain students, and state that any student guilty of such discreditable conduct is liable to rustication, or to expulsion from the University; and the Senate considers that any attempt on the part of a body of students to disturb the public peace calls for the exercise of academic discipline, and concludes by asking students, whose conduct inside the walls has been exemplary, to render impossible any repetition of proceedings which may bring discredit on the University.

MATRICULATION OF STUDENTS AT THE UNIVERSITY OF EDINBURGH.—Since the number of students who have matriculated this session at the University of Edinburgh was last

mentioned, the enrolments have showed a further increase as compared with the figures for last year, which were unprecedented in the history of the university. Up to the present date the number of students who have matriculated is 2,867, as compared with 2,787 at the same date last year, being an increase of 80.

UNIVERSITY OF ABERDEEN.—HONORARY DEGREES.—At a meeting of the Senators of the University of Aberdeen recently held, it was resolved to confer the honorary degree of LL.D on Sir Erasmus Wilson, and Dr. Andrew Clark of London. Dr. Clark is a graduate of the University.

"DIPHTHERIA."—Buckle, in his magnificent work, remarks that the people who see ghosts, are those who are anxious to see them. So it is with the "diphtheria" alleged to be so prevalent in Glasgow. That indefatigable "discoverer," Dr. Robert Bell, has just published a pamphlet on "Diphtheria: its Cause, Cure, and How to Prevent it." Since Dr. Aneas Munro's celebrated work "On Nursing" fell like a bombshell on the profession, no book which appeared in Glasgow has caused so much professional merriment as the one in question. "Healthy Womanhood" does not touch it. Dr. Bell, it may be stated, is author of "The Potato Disease," and considering that he does not hail from the sister isle, his observations on this subject are in the highest degree interesting. The pamphlet "On Diphtheria" is written in the Northumbrian tongue.

HEALTH LECTURES AT EDINBURGH.—These still continue to draw large audiences. The third which has just been issued is by Andrew Wilson, M.D., "On Parasites." We have carefully examined the *Medical Register*, but have been unable to [discover anyone corresponding to the person named above. In fact there is only one Andrew Wilson on the Register, but he does not reside in Edinburgh. We also notice on some magazines the name of Professor Andrew Wilson, M.D., Edinburgh. We have lived some years in Edinburgh, but have failed in our search to discover where Mr. Andrew Wilson is a professor, or where he obtained the degree of M.D. Perhaps the Professor may be able to enlighten us on the subject, for the description of himself is a little misleading.

Correspondence.

THE NOTIFICATION OF INFECTIOUS DISEASES IN EDINBURGH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of December 7th Dr. Littlejohn professes to give an accurate account of the proceedings connected with the recent alleged contravention of "The Edinburgh Municipal and Police Act, 1879." His statement is erroneous from beginning to end. He commences his marvellous epistle by saying that he received an anonymous letter, "stating that there were several cases of typhoid in a certain house." In the witness-box his version was, "the existence of fever;" not "several cases of typhoid." The following is the letter I received from him, dated 20th October:—

"Dr. Bowie, dear Sir,—My attention has been called to the existence of fever at No. 6 Caledonian Crescent, in a family of the name of Stoddart. By the late Municipal Act you are bound to report such cases at this office, and should feel obliged by your informing me why you have not done so."

I replied: "Dr. Littlejohn. Dear Sir,—I am not aware that medical men are bound to inform you of all cases of fever under their care. Perhaps you will kindly say where such information can be had, or send me a copy of the Act which compels me to do as you say. I have many reasons for not communicating all such cases in my practice to the medical officer of health, but if the law of the land makes it obligatory for me to report all such occurrences, I shall do so, but not unless."

The next note I received was a summons on November 1st to appear at the police court on the 3rd. It was the policeman who first called the diseases in question typhoid fever.

Dr. Littlejohn did not visit the house until the afternoon of the first day of the trial, and on evidence admitted that I was brought to judgment on the representation of his inspector. He says I "had conscientious scruples against reporting such cases." There were no scruples in the matter. The mother suffered from erysipelas of the throat, head, and face; the two children from an eight-day simple continued fever. The three witnesses for the prosecution testified that I told them that the children had a fever from gastric derangement, which, for want of a better name, some medical men would call it "gastric fever;" but that I distinctly said it was not typhoid fever, neither was it an infectious disease of any kind.

On examination by me Dr. Littlejohn stated that he did not examine any of the patients; could not say if there was diarrhoea, eruption, or pain in the abdomen; made no inquiries about complications, temperature, pulse—not even if they had a nurse. On being asked to inform the judge how he or his inspector knew typhoid fever without the symptoms, answered, "The long experience which he and his inspector had enabled them to discover a disease sooner than an ordinary practitioner."—*Daily Review*, Oct. 8.

I refrain from characterising the true nature of his remarks in your issue, such as "my inspector had to speak as to his obtaining the name of the medical attendant." The truth is, Dr. Littlejohn put him in the witness-box to swear that the cases were typhoid fever. "Charles Kay, assistant to Dr. Littlejohn, said he saw Mrs. Stoddart and children, and he had no doubt they were suffering from typhoid. Had Dr. Bowie reported the matter the cases would have been removed to the infirmary. He did not examine the bodies of the parties, nor did he notice any eruption. He examined the tongue, lips, and complexion, and concluded that it was a case of typhoid fever."—*Daily Review*, Oct. 8.

I am at a loss to understand why he says, "In consequence of this cross-examination by the defendant you have been led to believe, 1st. That the usual proceeding in Edinburgh is to send a police officer to confirm or not the diagnosis of the medical attendant; and 2nd. That it was on the strength of the policeman's diagnosis that the prosecution was commenced."

The first is the custom, and declared to be so by his inspector in giving evidence. The second was admitted to be true by Dr. Littlejohn when in the witness-box.

He continues, "I have only further to add that the case in question was not appealed, and that since the decision the medical man has regularly reported his cases to this office."

I regret that I was misinformed as to the nature of an appeal, and allowed the three days to pass by without going forward. Moreover, he knows I only notified a case of measles since the decision, and he dares to represent that single occurrence as "regularly reported his cases to this office." The grounds upon which the sheriff found me guilty in contravening the Act were:—

1. The sanitary policeman, from his experience, affirmed the cases to be typhoid.
2. He knows typhoid fever from the complexion, lips, and tongue of the patient.
3. In ten years' experience among such cases he has never seen any spots on the bodies of typhoid cases.
4. Dr. Littlejohn assured the judge that his inspector knows the disease better than an ordinary practitioner.
- "5. That gastric fever was synonymous with typhoid."
- "6. All fevers are infectious."
- "7. There was no class of fever that was recognised as non-infectious."

"8. That Murchison ('On British Fevers') holds all fevers to be contagious."—*Daily Review*, Nov. 8.

"9. Fever was equivalent to an infectious complaint, and the fevers in this Act included all the recognised fevers known."

I appealed to the judge not to believe these most extravagant and unfounded assertions, and requested the sheriff to hear my statement, but he refused, and said he knew nothing about medicine, and as Dr. Littlejohn had stated on oath that all fevers are infectious, he must find me guilty.

I am, sir, yours, &c.,

JOHN BOWIE.

43 Lauriston Place, Edinburgh.

THE GERM THEORY OF DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read carefully the lecture on the germ theory of disease by Dr. John Dougall lately published in your columns. Will you allow me space to put the *status questionis* clearly, which, it appears to me, the lecturer has not done. It is agreed that it is a virus which produces zymotic disease.

The physico-chemist asserts that the virus is *dead*, that it is a decomposing albumenoid, and that it acts on other bodies by catalysis, which may be likened to the decomposition of a small quantity of fulminate exploding a magazine of dynamite.

The germist asserts that the virus is *living*, that it is cellular, and that its action on other substances is a vital one.

The kernel of the controversy lies in whether the virus is living or dead? Whether it be cellular is a secondary matter. Whether, if it be cellular, these cells are vegetable as to their classification is still more remote from the immediate question.

Now there is a hitch in the logic of the physico-chemist, for his physico-chemical theory which he puts forward as an explanation of the phenomena of contagion, is not a theory at all, but an isolated fact, which itself needs explanation. For example, a portion of decomposing albumenoid is put into a solution of sugar kept at a certain temperature, the sugar is changed into carbonic acid and alcohol, but if the temperature is raised a little more, the action is stopped altogether. Now this is an occurrence for which neither chemistry nor physics affords either explanation or analogy, whereas it is exactly paralleled among vital actions. What the decomposing albumenoid appears to do in a solution of sugar, the protolytic ferments of the body most certainly do in various solutions, and that in virtue of their being not dead and decomposing, but living and active. The same temperature, too, which stops all action in the one case, does so in the other also.

If it be proved that along with the dead decomposing albumenoid, which is used as ferment, there are always introduced living cells into any solution, the analogy of the case to that of the vital ferments is so complete that it looks very like as if the "physico-chemical theory" had gone over bodily to the germist side, and ranged itself as one case among many others of the action of a vital ferment.

When I was student in the Edinburgh University, I recollect one of the professors ridiculing the idea that spermatozoa had anything to do with conception, and amusing his class by a description of the little manikin finding his way up to the ovaries. I do not recollect whether one of his objections was that no microscopist could distinguish between the spermatozoon of a man and the spermatozoon of a monkey.

I am, sir, yours, &c.,

A. W. W.

LETT'S MEDICAL AND OTHER DIARIES.

We have received from Messrs. Letts and Co., copies of their well-known and widely appreciated diaries. The 1882 issue of these works is in every way on a par with those of former years, and the several varieties compiled for professional use are excellently adapted for their purpose. The rough diary for desk work is a model of cheapness and usefulness, and the smaller kinds for pocket use leave nothing to be desired. Messrs. Letts are so universally and favourably known as publishers of diaries, that the announcement that the 1882 issue is now ready is all that need be said concerning them.

RUDALL CARTE & CO.'S PROFESSIONAL POCKET BOOK.

A SOMEWHAT different arrangement characterises this book from any others that we have seen. The outer roan or leather cover is the same as others, but the interior is in four separate sections or quarters of the year, so that only one section need be carried in the pocket, which in turn can be discarded as another quarter arrives. This has its conveniences, but is at the same time not free from drawbacks. The workmanship of this is decidedly of a good class.

The Harveian Society of London.—The following is a list of the names of Gentlemen proposed by the Council as Officers of the Society for the year 1882. *President*.—W. Hickman. *Vice-Presidents*.—J. Milner Fothergill, M.D., H. Sewill, M.R.C.S., *W. B. Cheadle, M.D., *H. Cripps Lawrence, F.R.C.S. *Treasurer*.—James E. Pollock, M.D. *Hon Secretaries*.—M. Morris, F.R.C.S., W. H. Lamb, M.B. *Council*.—*Henry Power, F.R.C.S., *George P. Field, F.R.C.S., T. T. Whigham, M.D., Alfred Cooper, F.R.C.S., F. A. Mahomed, M.D., Osman Vincent, F.R.C.S., Robert Argles, M.R.C.S., W. Rayner, M.R.C.S., *D. Ferrier, M.D., *J. Knowsley Thornton, M.B., *H. W. Kiallmark, M.R.C.S., *J. H. P. Staples, M.D. An Asterisk is prefixed to the names of those gentlemen who did not hold the same office the preceding year.

NOTICES TO CORRESPONDENTS.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

SURGEON-GENERAL GORDON.—We have deferred the insertion of your letter to the first number of the new volume in January, when we shall be happy to open our columns to a discussion of the points raised.

MR. GILSON.—It is our rule to refrain from recommending any particular physician in our columns. Yours is a case that any competent general practitioner should be able to treat successfully.

DR. S. S. E.—Unfortunately the case to which you refer is of everyday occurrence, and detracts from the dignity of the profession. In so large a body, and where indirect competition is so keen, numbers are sure to descend to the despicable depths to which you allude, but it would involve us in another action for libel to mention names.

DR. R. NEALE.—We have much pleasure in acceding to your request.

DR. WAHLTOCH (Manchester).—The administration of the provident dispensary system in Manchester and Salford appears to be fraught with serious consequences, both to the profession and the public; abuses of all kinds have been allowed to go on unchecked, and to have considerably impaired the usefulness of a well-intentioned effort of medical relief. We shall make further inquiries and revert to the subject more fully in a future number.

MR. J. RICHARDSON.—We hear that several hundreds of the profession and the public have written to the family of the deceased Earl with suggestions as to the whereabouts of the stolen body. Your hypothesis falls to the ground in face of the latest telegrams, and we are reminded forcibly of the passage in Hood's poem, "Mary's Lament," in which the dead girl is supposed to be thus speaking to her lover:—

"I thought the last of all my cares
Would end with my last minute,
But though I went to my long home
I didn't long lie in it.

"The body-snatchers, they have come,
And made a snatch at me,
It's very hard them kind of men
Won't let a body be.

"You thought that I was buried deep,
Quite decent-like and chary,
But from her grave, in Mary-bone,
They've come and boned your Mary.

"The arm that used to take your arm
Is took to Dr. Vyse,
And both my legs are gone to walk
The hospital at Guy's."

DR. SEGUIN (New York) is thanked for his communication, which shall receive early attention.

DR. J. S. GREEN.—Your paper is marked for early insertion in the new volume.

ECZEMA ASSOCIATED WITH INFLAMMATION OF THE CONJUNCTIVÆ.—A QUERY.—A. W. asks what is the best remedy for eczema palpebræ associated with chronic inflammation of the conjunctivæ?

[*] A lotion of nitrate of silver, one-tenth of a grain to the ounce, should be dropped into the eye three or four times a day, and the red oxide of mercury ointment (N.B. not the golden ointment which is usually employed) should be applied to the roots of the eyelashes. Before applying the ointment the secretion should be washed off with warm soap and water. The strength of the ointment required differs in different people. If redness increase immediately after the application, reduce the strength.—Ed.]

E. H.—Do not hurry; we can wait very well; put more time in the work, it will be the better for it. We will forward the papers to the War Office if you still think it advisable.

DR. CLINTON.—The remarks were made in good faith, and with an intention to attract the notice they have received. If they have offended you we are sorry of course, but they will most certainly not be withdrawn.

YOUNGER SON.—The medical profession offers noble prospects to every earnest and determined man. Enter it by all means if you have a liking for it.

DR. SURTER.—The discussion referred to was "On Cancer," opened

by Mr. C. de Morgan at the Pathological Society in March, 1874. A full report of the discussion is contained in the "Transactions" of the Society, vol. xv.

PUBLIC INQUIRY INTO THE HOSPITAL SYSTEM.—A meeting of the Social Science Association will be held to-day (Wednesday), at 3 p.m., when a paper by Mr. Timothy Holmes, F.R.C.S., "On the Necessity of a Public Inquiry into our Hospital System," will be read and discussed. The meeting, which will take place at the rooms of the Association in the Adelphi, has been convened in consequence of the Council having been requested by the Health Section at the recent Congress to take steps with a view of promoting an inquiry into the administration of hospitals.

Vacancies.

Ballina Union, Crossmolina Dispensary.—Medical Officer, Salary, £20, and £20 as Medical Officer of Health. Election, Dec. 24 (See Advt.)

Birmingham General Hospital.—Surgeon on the Honorary Staff. Must be a Fellow of the Royal College of Surgeons of England, Ireland, or Scotland. Applications to the House Governor by Dec. 21.

Brompton Consumption Hospital.—Physician on the Staff. Honorary Applications to the Secretary by Dec. 28.

Castle Ward Union, Northumberland.—Medical Officer of the Workhouse and District. Salary, £50, exclusive of the usual fees. Applications to the Clerk at Highways, Morpeth, by Dec. 20.

Charing Cross Hospital, London.—Medical and Surgical Registrar. Full particulars to be obtained of the Secretary.

Killala Union, Ballycastle Dispensary.—Medical Officer. Salary, £11, and £20 as Medical Officer of Health. Election, Dec. 29.

Monmouth Union.—Medical Officer for the Monmouth District. Salary, £40, with the usual extra fees. Applications to the Clerk of the Union by Dec. 30.

Mullingar District Lunatic Asylum.—Resident Medical Superintendent. Full particulars on application to Dublin Castle. (See Advt.)

Warnerford Hospital, Leamington.—House Surgeon. Salary, £20, with board. Applications to the Secretary by Dec. 27.

Appointments.

BROWN, A. S., M.R.C.S., Medical Superintendent of St. Mary's Hospital, London.

CARTER, G., M.R.C.S., House-Surgeon to the South Devon and East Cornwall Hospital, Plymouth.

DENNY, C. J., L.R.C.P.F., M.R.C.S., Medical Officer for the Southhurst District of the Easthamstead Union.

INGERS, J. W., M.R.C.S., Medical Officer for the Fourth District of the Nottingham Union.

LAMBREK, F. F., L.R.C.P.Lond., M.R.C.S., House Surgeon to the Liverpool Royal Infirmary.

MCCORMICK, A., M.B., M.R.C.S., House Surgeon to the Liverpool Royal Infirmary.

MCCOURBRY, D. M.D., M.C.Q.U.L., Medical Officer for the Slihan District of the Penistone Union.

MASTERS, J. A., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Hednesford District of the Cannock Union.

MONEY, A. M.B., M.R.C.S., Medical Registrar to the Hospital for Sick Children, Great Ormond Street, London.

RAYNER, H., M.R.C.S., House Surgeon to the Liverpool Royal Infirmary.

STOOKES, A., L.R.C.S.Ed., House Physician to the Liverpool Royal Infirmary.

THOMPSON, M. B., M.B., C.M. Edin., House Physician to the Liverpool Royal Infirmary.

UTZHOFF, J. C., M.D. Lond., M.R.C.S., Honorary Surgeon to the Sun and Brighton Eye Infirmary.

WILLIAMS, W. R., F.R.C.S., Surgical Registrar to the Middlesex Hospital.

Births.

FASKALLY.—Dec. 14, at Sidmouth, Devon, the wife of G. R. Faskally, F.R.C.S.Ed., of a son.

HUTCHESON.—Dec. 12, at Brighton, the wife of Surgeon-Major G. Hutcheson, M.D., H.M.'s Bengal Army, of a daughter.

STEWART.—Dec. 13, at Glaslough, the wife of Dr. R. William Stewart, of a son.

TEEVAN.—Dec. 14, at 116 Netherwood Road, Kensington Park, W., the wife of Alfred Teevan, M.R.C.S., of a daughter.

Deaths.

BARLOW.—Dec. 8, at Writtle, Essex, J. N. Barlow, M.R.C.S., L.S.A. Lond., aged 64.

BATTERSBY.—Dec. 13, at his residence, 45 Wellington Road, Dublin, Robert Battersby, F.R.C.S.I., Deputy Inspector-General of Hospitals, aged 79.

BERKELEY.—Dec. 10, at the District Lunatic Asylum, Mullingar, Henry Berkeley, M.D., Resident Medical Superintendent, aged 78.

HOPGOOD.—Dec. 6, at Slough, Bucks, Joseph Hopgood, M.R.C.S., in his 69th year.

NEWSHOLME.—Nov. 10, at The Green, Hellfield, Henry Withness Newsholme, M.R.C.S., aged 72.

STEELE.—Nov. 27, at Abergavenny, Elmes Yelverton Steele, M.R.C.S., aged 69.

WANTED, by a MIDDLE AGED MAN, who has had great experience as a Dispenser—a similar situation with a professional gentleman. Can keep books, and extract teeth—Town or country. Excellent references. C. B., 63 Gloucester Terrace Hyde Park W

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 28, 1881.

RETROSPECT OF THE YEAR 1881.

England.

INTRODUCTORY.

EIGHTEEN HUNDRED AND EIGHTY-ONE will ever remain a year memorable in the annals of medicine as being that in which the most imposing and successful gathering of all that is great and good in connection with the profession took place. The future historian of the time we live in may not perhaps be able to chronicle so many brilliant triumphs of the surgeon and the physician over disease and death as will perchance be associated with the years yet to come, but it will, notwithstanding, be for ever true that the year just past gave birth to a spirit of progress which must, sooner or later, be fruitful in the extreme. Never before has the profession of medicine occupied, in the general estimation, a position so honourable as that to which it now lays claim; never before have its professors received the homage of the people in the same manner that it is now accorded to them; and never before, finally, have there been crowded into the narrow limits of a single year so many significant events as have marked the season intervening between this and the preceding retrospective number of the *Medical Press and Circular*.

It is not, as we have remarked, that an unusually large number of brilliant improvements, of perfected operations, or new discoveries, have been achieved within the time, though, in each respect, the year has been by no means less remarkable than many preceding ones; but above all, 1881 is distinguished for the impetus given to universal medicine through the most notable scientific gathering ever convened.

THE INTERNATIONAL MEDICAL CONGRESS.

In comparison with this event all others shrink to insignificance, and now, nearly four months subsequently, we are able to judge at greater advantage the influences exerted by it. The Congress assembled in London on August 3rd, and remained in Session seven days. During this time daily meetings were held in different places for

the reading and discussion of papers, which were classified, according to their nature, under seventeen different heads. Any detailed account of the vast collection of monographs thus produced would be impossible here; some of the most notable will find a place further on under its appropriate sectional headings, but this is, perhaps, less to be regretted since the absorbing interest excited by the proceedings of the Congress, ensured a certain familiarity with the work accomplished by it. The first value of this, however, is to be sought less in the actual achievements in the sections, great though these undoubtedly were, than in the influence unquestionably exerted by the Congress on the progress of medicine throughout the world. Stores of knowledge, to serve for many a day, were added to our possessions, and a healthy stimulus given to the "science of improvement" by mutual intercourse of the three thousand or more medical men who thus met for a common object; but greater than all this is the loftier position thenceforth assumed by the profession itself, from the tacit admission of its claims on the part of social leaders who have not previously been wont to lend personal influence to its support. We may not, perhaps, be quite willing at first to admit the extent to which the success of the Conference, and the nature of all the consequences flowing from it are due to this particular, but none the less the fact remains, and we may, with better grace, accept than deny it.

The Congress was attended by the *élite* among medical men from the chief European and American cities, and the reception accorded to them by the general public, who eagerly assisted the endeavours of the profession to do honour to our foreign guests, has produced an impression on the minds of these visitors, which finds reflection in the pages of our contemporaries in every language and every land. Scientific discussions occupied the early portion of each day of the Congress, and in the afternoon a series of general addresses were delivered

before crowded audiences in the St. James's Hall by Sir Jas. Paget, who gave the presidential oration, Professor Virchow, Dr. Billings, Prof. Volkmann, Prof. Huxley, and also one which had been prepared by the late Prof. Reynand before his death, and which was read by Dr. Féréol at the second general meeting. Public dinners, soirées, *conversaciones*, excursions and garden parties were among the amusements provided for the entertainment of members of the Congress during their leisure hours, and it may be safely said that the hospitality so freely shown, and willingly accepted, will always be regarded by those who were its recipients as an invaluable proof of the universal brotherhood which reigns among medical men throughout the world.

THE BRITISH MEDICAL ASSOCIATION

held its annual meeting for 1881 at Ryde, Isle of Wight, and timed it to follow immediately after the great Congress. The change from the heat and turmoil of London, and the incessant engagements of the preceding week to the calm, cool, seaside town, was a welcome relief to not a few of those who had been busiest at work. The meeting of the Association was naturally not so considerable as usual, many who would otherwise have spent time in attending it, having elected to be present at the more important Congress; notwithstanding, however, over 300 members and foreign visitors put in an appearance, so that the proceedings were by no means uninteresting from the absence of audience; but scarcely more was ever anticipated than that the meeting would be a sort of "fag-end" to the Congress itself. It acquired, however, an unexpected notoriety from the nature of the addresses delivered by the President, Mr. Barrow, and the Presidents of the sections of medicine and surgery, Dr. Bristowe and Mr. Hutchinson. All these, strangely enough, practically dwelt on the same theme, viz. homœopathy and consultation with homœopaths; and all these, moreover, sanctioned by their approval the hitherto condemned practice of consultations between practitioners who do and do not recognise a science of medicine. This action on the part of leaders in medicine and surgery, speaking as they then were, *ex cathedra*, naturally excited much heated controversy which cannot yet be said to have ceased. They also did such injury to scientific practice as will not quickly be remedied, for by thus unwisely admitting to an equality, practitioners whose theories they did not hesitate to condemn, they in a sense authorised proceedings never previously regarded with approval by regular practitioners. The statements of opinion, however, were purely arbitrary and personal, and have been expressly disavowed by the Council of the Association; and it may, perhaps, not unjustifiably be hoped that the strong and all but united protest raised against the view taken by the authors of the Ryde addresses, will have a due effect in suppressing any desire to adopt the suggestions therein contained on the part of the general body of the Association.

GENERAL MEDICAL COUNCIL.

The General Medical Council held but one public Session during the year, at which even less real work was accomplished than has been usually the case with

this body. The chief questions for consideration were those relating to admissions on to the register of dentists, and to the preliminary examination of candidates for medical qualifications. In connection with the dentists' registration, the Council showed itself more than usually careless of public opinion in the profession, for in spite of it, and in direct opposition to its own legal adviser also, it insisted on granting the same license to hair-dressers and mechanics who claimed to be dentists, as had already been accorded to them by the ridiculous terms of admission to the *Dentists' Register*. Efforts had been made by regularly qualified surgeons practising dentistry to influence the Council in favour of purifying the list, and the minutes contained several reports and letters on the subject, addressed to the Council with a view to affecting its decisions. It is not, therefore, surprising that the dentists regard themselves as having been unjustifiably inveigled into the anomalous position they now occupy as the registered associates of unqualified pretenders. Nor can they be blamed for this, as the Council is chiefly responsible for the creation of the anomaly, and is certainly mainly instrumental in maintaining it. This, moreover, is what dentists have gained by sanctioning measures for transferring the conduct of their affairs to a body which had again and again proved its utter incompetency to do aught for the advantage of the profession it is assumed to support. This, too, is that for which dentists have consented to pay a large annual sum of money, and is all that they are ever likely to obtain.

The usual wearisome discussion on preliminary education occupied a prominent place in the Council's proceedings, and terminated as unsatisfactorily as any preceding debate of the same description. It almost appears as though barren results are inseparable from the deliberations of what is, in reality, the parliament of medicine; and, in fact, were it not for the enterprise and energy sometimes shown by a few of the corporations that ought, in reality, to be directed how to progress by the Council, there would be nothing to chronicle in the way of advance in educational medicine. Far from simplifying or expounding the system of instruction, the Council, by its interminable debates and recommendations and counter-recommendations, has done more to bar improvement than the obstructive influence of all the examining boards together. Even in the last Session of the Council was this well shown, when attempts were made to re-enact old, discarded measures, having for their object further complication of an already burdened curriculum. The work actually accomplished consisted in formulating and adopting propositions to accept the higher examinations of the College of Preceptors as an equivalent for that of the Royal College of Surgeons in Arts, which has been held for the last time in the present year. The example thus set by the English College might well be followed in other cases, but the action of the Council in continuing to acknowledge the well-nigh numberless examinations admitting to registration as a medical student affords little hope of any immediate palpable diminution of them.

Of the nature of work this constitutes all that the Council accomplished in a sitting of several days' dura-

tion, unless it be added that after some six hours' consideration, it decided to remove from the register the name of a Scotch practitioner who had been guilty of grossly unprofessional conduct, and whose case might have been easily settled on its merits after twenty minutes debate. In its *personnel* the General Medical Council has undergone considerable changes within the past twelve months. Of its members no less than four have been removed by death, viz., Drs. Andrew Wood, George Rolleston, Hudson, and McClintock, the last named having but a short time previously been appointed in succession to Dr. Hudson as Crown representative for Ireland. His place is now taken by Dr. Lyons, of Dublin. The Council has likewise suffered the loss of its legal adviser by the decease of Mr. F. Ouvry, who had long been regularly entrusted with the conduct of all business appertaining to the Council in its legal functions.

Sir James Paget's term of office as representative of the Royal College of Surgeons of England having expired, and Sir James declining to be re-elected, Mr. John Marshall has been appointed to succeed him in this capacity, while Mr. Spence replaces Dr. Andrew Wood.

In other respects the constitution and conduct of the General Medical Council calls for little comment. It exhibits no signs of throwing aside the characteristics which have distinguished it as a model of "masterly inactivity;" nor is there any indication to show that it has at last awakened to a consciousness of its own uselessness, a fact long patent to every observer of its proceedings.

ROYAL COMMISSIONS.

Two Royal Commissions in connection with the medical profession have sat during the year to receive evidence, the one in relation to the Medical Acts Amendment, and the other with respect to fever hospitals, and modes of meeting fever epidemics in towns. The first of these was composed of a number of gentlemen a majority of whom are not members of the medical profession. Its Chairman was Lord Camperdown, and it held a long series of sittings, receiving the evidence of a very considerable number of witnesses representing the various corporations and boards interested in the new bill to be introduced. The nature of the evidence is not yet disclosed, the Committee having elected to sit with closed doors. It is now considering its report, which may be expected ere long to be made public. There is reason to believe, however, that the scheme put forward in this paper will be very nearly that to which approval will be given: that is, that a single uniform examination will be recommended as the test for admission into the profession of medicine, this examination to be conducted by a board on which the various licensing bodies will be represented. Direct representation of the general practitioner's class on the Medical Council will be provided for by the practical extinction of three existing bodies, viz., the Apothecaries' Societies of London and Dublin, and the Faculty of Physicians and Surgeons of Glasgow; and further powers will be conferred on the Council to punish illegal practice; the Council, in fact, will, under a new Act, assume the functions which it has so long merely played

at discharging. Such are the principal points to which the Report of the Royal Commission may be expected to direct attention; it will, probably, also deal with a multiplicity of minor but important subjects bearing on the detailed carrying out of the scheme as above sketched forth. The second Commission, that on Fever Hospitals, is presided over by Lord Blachford, and has held several sittings already. Its report will not be ready for some time.

VIVISECTION AND ANTI-VIVISECTION.

Those restless persons who devote their time and attention to fomenting agitation against the progress of science along the path of experimental research, have, during the last few months, been more than usually busy. It might have been expected that occasion would eagerly be sought in the proceedings of the International Medical Congress for fastening the charge so dear to anti-vivisection sympathies, as that of cruelty under the guise of science. As a matter of fact this really occurred, and Professor Ferrier, of King's College Hospital, was summoned before the magistrate at Bow Street to meet an accusation of illegal vivisection, brought by the Victoria anti-vivisectioners. The basis of the charge it will be remembered, was contained in certain reports of a speech made by Dr. Ferrier on the opening day in the physiology section of the Congress, when he met in debate Prof. Goltz on the functions of different cerebral areas. A demonstration followed the discussion, and Dr. Ferrier illustrated the remarks he had made by exhibiting two monkeys which had been operated on after a manner described by him, while Prof. Goltz showed a dog in proof of the assertions he had made. On this ground Dr. Ferrier was cited to answer the charge of illegal vivisection, he not being duly licensed to pursue the study of physiology on the lines laid down by the Act of Parliament. Naturally, the summons was dismissed, the astute advocates of ignorance having omitted to assure themselves that Dr. Ferrier *did* actually perform the experiments himself. These were in fact, carried out by Dr. Yeo by authority of the Government license, and thus the whole prosecution miserably collapsed. The incident however, clearly enough shows that every means will henceforth be adopted by anti-vivisectioners to develop the craze they advocate, to the utmost possible extent; and on the same measure will hindrances be opposed to experimental research in this country. There are not wanting either indications of unwillingness on the part of those with whom the granting of licenses depends, to interpret the law in its freest sense. Licenses indeed, have already been refused to the most eminent surgeons England can boast of, and many others also have been compelled to lay aside the prosecution of special studies because of the silly and fanatical opposition to practical physiology expressed by the societies maintained with that object. So serious has the evil now become, that it is generally admitted in the profession that something further than passive resistance must be indulged in if the malign influence against which physiology struggles in vain is to be fairly met and conquered. Hence the necessity that is recognised of a medical and scientific defence committee, charged with the duty of exposing

and defeating the tactics of anti-vivisection zealots; this decision, to check by personal influence the mischief so long allowed to work damage in our midst, has been arrived at none too soon, and we may hope for some speedy sign of its successful outcome.

It is cheerful to turn from what has been done to kill science to that which has been uttered on its behalf, and of the speeches directly addressed to vindicating the claims of the experimental method. We have this year heard several that will never cease to echo in the ears of every listener who was present when they were delivered. Chief among these declarations must be remembered the great oration of Prof. Virchow before the Congress, and that pronounced by the Father of English physiology, Prof. Owen, on the occasion of unveiling the Harvey memorial at Folkestone, in the presence of a numerous assemblage of visitors to London for the Congress. In addition to these admirable declarations of the benefits conferred on humanity through information yielded by experimentation on the lower animals, scarcely a single speaker of note in all the meetings of the Congress failed to lend, directly or indirectly, testimony in the same important cause; and more recently in connection with the Ferrier prosecution eloquent and powerful demonstrations of the value of vivisection as an engine of advance, have poured forth from pens innumerable in the professional organs of public opinion.

It remains, however, that the time has gone by for temporising with fanatical obstructions to science, organised by the various societies which avowedly exist for the sole purpose of fostering a non-scientific spirit. Active and energetic counter measures are urgently demanded from the profession of medicine itself, and it is hopeful to note that a general consensus of belief to this effect is showing itself among its members. Soon, possibly, a change for the better will be evident.

THE GERM THEORY.

In the hands of M. Pasteur the germ theory has made important advances during the past year, and the marvellous results achieved by this French chemist, communicated by him to the Medical Congress at one of its general meetings, have been deservedly followed by the election of their author into the dignified circle of the Academie Française. The researches inaugurated by investigation into the causes and consequences of chicken cholera, and its mode of propagation, led Pasteur to further experimentation to determine the possible modes of preventing transmissible disease. The sum and substance of these inquiries is contained in the unparalleled success attending treatment of animals subject to infection of splenic fever and chicken cholera, by vaccination with the attenuated virus of the disease itself. The chief claim of Pasteur in this connection is embodied in his assertion that by such means he is enabled to fortify unaffected animals with the power of resisting serious consequences in even the most rankly infected districts, together with the discoveries whereby he has succeeded in virus culture to a degree that is marvellously perfect. The interest attaching to the particular address in which the methods of investigation pursued, and the results ob-

tained by them, was strikingly manifested in the eager attention with which the lecture was received by a crowded and enthusiastic audience. The mode by means of which M. Pasteur prepares his cultivated attenuated virus for employment in inoculation experiments, is one of those wonderful proofs of the genius he exhibits in all that emanates from his fertile invention. He shows that atmospheric oxygen is the agent intervening between two cultures, and to it he ascribes a modifying influence on the development of disease germs in the bodies of animals. His words are, "Let us produce a culture in a tube containing very little air, and close this tube with an enameller's lamp. The microbe, in developing itself, will speedily take all the oxygen in the tube and the liquid, after which it is quite free from contact with oxygen. In this case it does not appear that the microbe becomes appreciably attenuated, even after a great lapse of time. The oxygen of the air, then, would seem to be a modifying agent of the virulence of the microbe of chicken cholera—that is to say, it may modify more or less the facility of its development in the bodies of animals. May we not be here in presence of a general law applicable to all kinds of virus? What benefit may not result? We may hope to discover in this way the vaccine of all virulent diseases." This, indeed, is what we are now bidden to expect, and in respect of one disease at least, viz, Charbon or splenic fever, it can be confidently asserted that the experiments conducted by Pasteur on living animals, in conjunction with his own chemical researches in the laboratory, have armed the French farmers with an agent which, employed for inoculating cattle, effectually preserves the latter from the ravages of charbon as certainly as vaccination preserves from small-pox. Already has the discovery borne valuable fruit in France, and in view of the facts, against the truth of which no evidence has been attempted as yet, we may hopefully anticipate this phase of the germ theory will yet be a boon of health to humanity.

Incidentally the germ theory has received frequent illustrations during the year, and the influence it exerts over the spread and extent of disease has been again and again manifested by observers in the field of practical medicine. Later on we shall be recalled to it. The chief and most important contribution to the literature of the subject, however, is undoubtedly the address of Pasteur referred to above.

A meeting was held last week for the purpose of taking into consideration the necessity of forming an association of medical and scientific men to act in defence of scientific interests by combatting the ignorance and prejudice existing in the public mind on the question of experimental research. This will be followed by a large general meeting, at which further discussion will take place, and a united society, with these objects in view, be formed. We may therefore expect a speedy removal of the dense ignorance which now reacts so detrimentally to progress in medicine and surgery; and none too soon will the relief be obtained.

MEDICINE.

TYPHOID FEVER AND ITS TREATMENT.

The influence of individual constitution as determining the onset and course of typhoid fever, has been insisted on by Dr. Henry Kennedy, of Drumcondra, Ireland. He asserts his conviction that it chiefly occurs in persons who are either strumous, or of a constitution closely allied to struma, and in connection with this he insists on the dangers to be apprehended from hæmorrhages in such persons. Numerous reasons for the existence of the assumed connection are given by Dr. Kennedy in addition to those his own observation affords, such as the frequency of lung affections in typhoid, strumous markings, often found in typhoid patients, &c., and he urges a recognition of the association he demonstrates as being of signal importance in relation to treatment and prognosis. Dr. Kennedy is averse also to prohibiting stimulants, considering that no type of fever bears them so well as typhoid; and on the subject of diet he is strong in condemnation of the unlimited employment of milk, which he avers is often given in direct contradiction to the powers of digesting it the patient possesses. In this respect the authority of Sir Wm. Jenner supports Dr. Kennedy, whose conclusions are summed up as follows: 1. That the constitution in which typhoid fever occurs is very generally tainted with struma. 2. That a consideration of the morbid states found in the abdomen, not only in typhoid, but in other fevers, accounts most satisfactorily for the varied phases which typhoid presents. 3. That as we have a distinct morbid lesion to contend with, our treatment should be regulated accordingly. 4. That wine, or other stimulant, should constitute a part of the treatment of typhoid fever. 5. That the use of milk in the treatment always demand special consideration. 6. That both leeches and blisters may be used with decided advantage, for either the abdominal or chest symptoms of typhoid. 7. That at an advanced stage of the disease aperients are frequently of much benefit.

Anti-pyretic treatment of typhoid by the salicylate of soda is advocated by Dr. Henry Tomkins, Medical Officer to the Monsall Fever Hospital at Manchester. He records the results obtained by this method in forty-six cases, twenty-eight males and eighteen females, varying in age from seven to fifty-six years. They represent only one-third of the total number of cases in the hospital. During the period trial of the treatment was made, and in every instance where the salicylate was employed the temperature in the axilla ranged over 102°. The results were satisfactory, and the general treatment resorted to is thus described: "Perfect rest, milk diet, with small quantities of beef tea, acid and opium when diarrhoea is excessive; acetate of lead or turpentine, with iced injections, for hæmorrhage. Alcohol was never given, unless the state of the circulation decidedly demanded it, except in the convalescent stages of some few cases in the form of wine." Fifteen to twenty grains of the drug were given every two hours when the axilla temperature exceeded 102°, and a reduction of two or three degrees usually ensued

after six hours. Otherwise the same dose was continued until remission occurred, when it was reduced one-half, being increased if much evening exacerbation took place. The duration of the treatment varied from three to ten days, when a normal temperature would be restored in all but a very few cases. Alcohol in the form of brandy was freely administered in a small number of instances.

Dr. C. E. Shelley, of Hertford, recommends the anti-septic treatment of typhoid by carbolic acid and tincture of iodine administered internally. The formula he adopts is a modification of Rothe's, and is as follows:—One to two minims of carbolic acid; one to three minims of tinct. iodi; half a drachm of simple syrup; and an ounce of lemon water. The doses given every two, three, or four hours, or less frequently, and no untoward consequences were obtained.

The search after a typhoid germ has resulted in certain discoveries by Klebs, whose results are described as follows by a correspondent of the *Philadelphia Medical Times*:—

Klebs claims that he has proved that there exists in typhoid fever a separate and special bacillus—the bacillus typhosus; that it undergoes certain transformations, consisting at first of little rods and small fine threads, containing a spore in the centre, and often at the end (which spores divide off and form new bacilli); it later assumes a longer thread-like form, twisted at the end and frequently taking a beautiful spiral shape; that the bacilli are observed first in the masses of epithelial cells, which accumulate in the alimentary tract or in the air-passages; that they later penetrate the tissues, and are carried along by the blood vessels and the lymphatics, and form a large network among the tissues they invade; that under a certain procedure, which never causes this same staining on any other living organism or tissue, they appear of a blue colour; that they are found only in enteric fever, in which disease every part of the human body is the seat of masses of these bacilli, their quantity corresponding exactly with the severity of the symptoms; and that they produce, when carried into the system of animals, exactly the same disease with the same morbid alterations as typhoid fever in men.

Klebs has proved by a number of dissections that the cold water treatment influences the disease very little, but produces rather damaging results in a majority of cases. He suggests a remedy which decidedly influences and shortens the disease, viz., the benzoate of sodium or magnesium, used as a gargle, by inhalation, and internally in doses of 320 grains per diem. He cites a case in which he especially had opportunity to observe the effect of this medicine. A physically very strong man, who worked in his laboratory the whole day, and was most of his time engaged with the culture of the bacillus typhosus, became affected with typhoid fever in what promised, to all appearances, to be a very aggravated and serious form. After nine days of treatment with twenty grains of benzoate of magnesium daily, all the symptoms and all the fever left the patient, and a rather remarkable weakness was the only symptom he complained of after that for some time.

Klebs recommends the benzoate instead of other similarly acting remedies, as salicylic acid, carbolic acid, &c., because the benzoates alone can be given in doses large enough to keep up a continuous disinfection without producing any disagreeable symptoms, which would necessitate a smaller dose or the total omission of the remedy, as is so frequently the case with either salicylic or carbolic acid.

FILARIA SANGUINIS HOMINIS.

Dr. Stephen Mackenzie has had under his care, in the wards of the London Hospital recently, a most interesting patient suffering from chyluria, and whose blood contained immense quantities of the entozoon named *filaria sanguinis hominis*. For a considerable time the man, who had been a soldier in India, was under constant observation, and careful study was made during this period of all the phenomena presenting. There was a well-marked periodicity of filarious activity, the organisms appearing at night, becoming most numerous about the middle term, and gradually diminishing as morning advanced. An interesting fact, moreover, was noticed, viz., that, by reversing the order of sleeping and waking, a like reversal of the appearance of filariæ took place; and many other observations were made, all tending to confirm and extend the information previously accumulated concerning filariæ. Necessarily, nothing new was added to our knowledge of the life-history of the parasite by observation of Dr. Mackenzie's patient, but the facts of clinical significance were recorded with a diligence and carefulness that give to the report prepared by Dr. Mackenzie a very high value as a contribution to the literature of the subject. Dr. Spencer Cobbold, Dr. Vandyke Carter, and others, discussed the paper read by Dr. Mackenzie at a recent meeting of the Medical and Chirurgical Society, at which a lively interest was shown in the subject of the debate. Since that time we learn that the patient has suddenly ceased to suffer from chylous condition of the urine, and no longer is infected by filariæ.

SURGERY.

THE CATGUT LIGATURE.

In his Presidential Address before the Clinical Society of London in January last, Mr. Lister confined his remarks entirely to a consideration of the catgut ligature. Replying to the question why his own experience with this ligature had been more satisfactory than that of many other surgeons, he gave two reasons to account for it; one, that he never ventured to tie an artery of considerable size in continuity without having taken pains to ascertain that the catgut was of thoroughly trustworthy material; the other, that he had adopted strict antiseptic precautions from the first to the very end of treatment in every case. On the importance of the latter provision he says, "so long as any part of the wound remains unhealed, antiseptic treatment of the strictest kind ought, I believe, to be employed. Even though the sore may seem to be superficial, there may still exist a sinus leading down to the site of the ligature, and, if ordinary treatment, as distinguished from antiseptic, be employed down this sinus, the septic process may advance and invade the ligature,

and inducing unhealthy suppuration and ulceration, may lead at last to disaster from hæmorrhage." Regarding the mode of applying the ligature, Mr. Lister employs a single reef knot, with short cut-ends, tying it sufficiently tightly to cause the giving way of the internal and middle coats. The latter point, however, is not regarded as essential, but if, as in the case of catgut, the form of ligature admits of it, the injury done to the deeper tunics is, he considers, advantageous, by leading to a salutary process of repair. Mr. Lister published for the first time in this Presidential Address, an improved method of preparing catgut for ligating purposes. This consists of the submucous cellular coat of the sheep's intestine twisted and dried, and subsequently 'seasoned' in a solution composed of chromic acid, 1 part; distilled water, 4,000 parts; pure carbolic acid, or absolute phenol, 200 parts. Catgut, equal to the weight of carbolic acid employed, is immersed in the solution, and at the end of 48 hours, it is sufficiently prepared. It is then taken out, dried, and kept for use in a 1 to 5 solution of carbolised oil. Mr. Lister explained also how the catgut within the tissues is alone acted on, and that, not by chemical solution, since the stitches of a wound, freely bathed in serum, remain unaltered, but "in some way or other by the living textures." He further asserts "it has never happened, so far as I am aware, that a ligature of catgut, when once the knot has been secured, has proved treacherous in the way of rupture of the cord. When mishap has followed its use, it has either been from slipping of the knot, from premature softening and absorption of the catgut (faulty preparation), or last, not least from putrefaction having been allowed to take place in the wound."

Dr. William McEwen, of Glasgow, published almost simultaneously with Mr. Lister, a mode of preparing catgut, which he describes as useful in most cases. The method consisting of adding 1 part of a watery solution of chromic acid, 15 to 20 parts of glycerine, steeping the hanks of cat-gut in this six or eight months and storing for use in carbolised glycerine 1 in 10. Such ligatures, it is claimed, produce no irritation, do not become too speedily absorbed, and admit of a firm, effectual, and reliable knot being tied.

Almost immediately after Prof. Lister's address on the cat-gut ligature had been delivered before the Clinical Society, two papers were read at the Royal Medico-Chirurgical Society by Mr. Treves and Mr. J. MacCarthy respectively, which tended to illustrate the incompetency of cat-gut ligatures to produce permanent occlusion of arteries tied in their continuity. The discussion on these papers brought out many points in connection with pathological considerations to lend it an especial interest. The condition of the ligated arteries after death was particularly shown to be only imperfectly understood, judging from Mr. Erichsen's admission that such a state of non-occlusion in vessels tied ante-mortem had not been recognised by him. It is a matter for congratulation, however, that further investigation was excited, and in Mr. Barwell's continuation of the subject we are supplied with an explanation of the results obtained by Messrs. Treves and MacCarthy, which may perhaps be regarded as satisfactory. Suspicion as to the efficiency of the ligature was created in Mr. Barwell's mind by the absence of clot

above or below the ligature in two out of the three cases reported on ; while in the third instance, where suppuration took place, perfect closure ensued. Moreover, this successful occlusion was in an artery tied (by Mr. Treves) with a single knot, the other unsuccessful cases having been tied with a double, and then a single, hitch. Mr. Birwell's explanation of the differences obtained is to the following effect : " If a piece of prepared cat-gut be drawn through the fingers it will rarely be found to be smooth, but to be roughened by little asperities studded over the surface. *These are not sufficient to obstruct in a knot made with a single hitch.* I tied, with a double hitch, a number of knots round different arteries, and I found that these roughnesses sufficed in the intensified friction thus produced to render the tightening of the first knot difficult, and even uncertain. In one or two instances the sense to my hand was that of having tied the experimental object tightly, the loop being afterwards evidently lax." He continues : " This, however, is only the hypothetical explanation ; the fact remains that two out of the three cases were tied with the double hitch, and in these two occlusion either did not take place or was very transitory." We may, with good reason, anticipate that further researches will be conducted with a view to arriving at a definite decision on this subject ; and it is, without doubt, a point on which accurate information is of the first importance as a guide to surgical treatment of wounds of all descriptions.

EXTIRPATION OF THE PYLORUS.

The present year has witnessed the performance of one of those daring operations which, in the eyes of many surgeons, do not appear to be justified by even the most extreme necessity. There are still a goodly number, of conservative tendencies it is true, who regard the regions open to operative surgical interference as being limited to those already ranked under so-called legitimate surgery ; but, fortunately for mankind, such narrow renderings of the license accorded to the operator, are not universally recognised by the profession, and, as time progresses, we may, with firm confidence anticipate that the triumphs of surgical art will advance also until there shall be no disease impossible of relief, and no condition not amenable to remedial measures employed in its amendment. Prof. Billroth, the greatest among the surgeons of Vienna, has done much in the past to lay claim to that admiration with which he is everywhere regarded, and now we have yet another instance of the success with which he essays and succeeds in the performance of operations such as, at no distant date, were regarded as impossible in the extreme. This consists in removal of the pylorus in those cases where it is invaded by carcinomatous growth. The first occasion on which this course was adopted was January 24th last. Patient, a female, æt. 43, presented all the symptoms of carcinoma of the stomach with stenosis of the pyloric orifice. Exhaustion was fast progressing when Billroth proposed the desperate remedy, and received permission to resort to it. The operation is thus described :—" An incision eight centimetres long having been made over the tumour, which was freely movable, it proved to be a nodulated carcinoma of the pylorus, the lower third of the stomach being involved. The parts were carefully separated from

the omentum, the vessels tied before wisdom so that subsequently very little blood was lost. The tumour having been completely brought on to the integument of the abdomen, an incision was made through the stomach one centimetre beyond the infiltrated part—first only backwards, and then through the duodenum. An oblique incision through the stomach was next directed, from above and inwards to below and outwards, always at a distance of one centimetre from the infiltrated parts. After uniting the oblique incision only sufficiently to allow of its being adjusted to the duodenum, the tumour was completely separated from the duodenum one centimetre from the infiltration, by means of an incision parallel to that made in the stomach. The duodenum was adapted to the aperture made in the stomach, about fifty sutures of carbolised silk in all having been employed during the operation. After cleansing with a 2 per cent. carbolic acid solution, and the application of a guard ligature, the parts were replaced in the cavity of the abdomen. The time occupied in the operation was one and a half hours, but the preliminary chloroforming took some time. The patient did very well subsequently, and lived for several months, and the success of the operation was most unquestionably established."

The same operation has been repeated on several occasions since, with varying results ; but although some discouragement has been naturally felt when it has been followed by no evidence of improvement, yet a due consideration of all the facts in connection with it should be held to modify any unfavourable judgment passed on it. It would, of necessity, be resorted to only in extremity, and thus but a minority of those subjected to it can reasonably be expected to recover. It does, however, offer the chance, and a fair chance, of prolonging life, and in this way it deserves to be ranked among perfectly legitimate operations. That it will ever become a common practice to submit patients suffering from cancer of the stomach to its risks is hardly to be expected ; but that in favourable cases it will be undertaken we are certainly justified in believing.

EXCISION OF THE UTERUS.

Excision of the uterus for the removal of cancerous growths has been brought into prominent notice very recently by reason of a successful case recorded by Mr. Spencer Wells, the organ, moreover, in this instance, having been in a gravid condition. The operation cannot of course be classed as a new one, except that Mr. Wells' case was surrounded by unusual circumstances, since it has been performed by a number of operators. It is to be hoped, however, that the renewed interest excited in the subject will lead to a fuller and detailed study of it in all its bearings, and that we may be placed in possession of sufficient information to be able to decide definitely on the chances afforded by it in the future. From the nature of such cases there are unusual difficulties to prevent successful issues in them. It is not until the disease to be attacked has made very considerable ravages that the question of removing its chief seat can be entertained ; and then there are the probabilities of constitutional disturbances to act as disturbing factors in the after progress of the patient. Nor from the histories of such cases, even the most successful, as that of Prof. Billroth, in which extirpation of

a cancerous organ is resorted to, can hope of absolute remedy be obtained. Sooner or later there is the certainty, there may be said, of a return of the disease with the equally certain train of attendant troubles, ending only in death to the sufferer. Notwithstanding this, however, the growing perfectness of the surgeon's art does at least offer amelioration, and, for a time, comparative freedom from disease; and this much is an addition for which we must needs feel grateful. In the present stage of surgery it may be said, then, that excision of cancer-stricken organs is a recognised operation, from which beneficial results have been unquestionably obtained, and from which yet greater benefits may by-and-by be looked for.

IMPROVED ANTISEPTICS.

The danger sometimes attending the employment of carbolic acid as an antiseptic agent in surgical treatment, and the comparative frequency of poisoning produced by it, have been illustrated several times of late. One case recorded by Mr. Pearce Gould at a meeting of the Clinical Society in May last is especially important, as in connection with it Mr. Lister explained that he had been devoting his attention to the question of replacing carbolic acid by a harmless antiseptic which should yet be equally valuable in its effects. The result of a lengthened series of observations had been the discovery of such a substance, in oil of *Eucalyptus globulus*. This is a powerful antiseptic, perfectly reliable, and its use is unattended by any injurious effects, no case so far, of constitutional susceptibility having been noticed at all comparable to that shown in respect to carbolic acid in numerous instances. Mr. Lister recommends the oil not to be made into an emulsion with spirit and water, in which form it very quickly evaporates, but that it should be mixed with dammar gum, such mixture long remaining soft, and smelling of the eucalyptus, even for weeks. He, himself, employed a gauze prepared with a mixture consisting of oil of eucalyptus 1; dammar 3; and paraffin 3; and in every case when he had employed it, the result had been most satisfactory. This discovery ought to prove of value in the future history of antiseptic surgery, and the worst charge it has to support in many respects, is that associated with the undoubted toxic effects not unfrequently produced by carbolic acid.

EXCESSIVE TEMPERATURE.

The question of unusual temperature has been freely discussed lately on more than one occasion, but the most notable instance is one recorded in minute detail by Dr. Stephen Mackenzie, and in which temperatures as high as 130 degs. had been registered. The patient, however, was a woman whose temperament was such as to induce a disbelief in her bona fides. The temperature, too, varied with so much irregularity, and under such strange conditions that no faith was entertained in their reality. The case however, was recorded as a sample of those that might be expected to present themselves, and since the publication of the paper the woman herself has confessed to Dr. Mackenzie that she had been guilty of imposture while a patient under him. Dr. Mahomed however, still considers that high temperatures do sometimes exist in hospital patients, even to 118 or 120 degrees, and with him Dr. George Harley is in agreement. The latter has

consented to present at a future meeting of the Clinical Society an account of several cases of unusually high temperature. The question, in fact, has received a certain share of the general attention, and it may be expected that it will ere long, be well sifted out.

BOOKS OF THE YEAR.

Medical literature has not been enriched by any considerable number of new books during the year just ending, but several of the contributions to it possess the highest intrinsic importance, and are entitled to rank among the more valuable works of reference. Of minor text books, and guides to various branches of professional practice, a goodly array of volumes has been, it is true, issued, and while, admitting the general excellence of their contents, it is, notwithstanding, impossible to regard them, as a whole, as evidencing any remarkable advance over similar classes of works published in previous years. The preparation of student's manuals, it should be remembered, in this connection, is a task that requires for its successful accomplishment somewhat unusual power of demonstration combined with ripe experience and a lucid expression that are to be found and expected only in those who have been for some time engaged in the labour of teaching. By malcontents who give free expression to dissatisfaction at the slow advances made in this direction by authors, this circumstance is, we must insist, too little considered. It quite sufficiently accounts for that poverty of books possessing "standard" value that is so much complained about, and should be held in view while passing judgment on the literary activity of any age or season. Moreover, the very persons who must of necessity be the ones to produce guides for students' use, are at all times busily engaged in the actual instruction of students, and are thereby prevented from giving the time and close attention to composition, without which no really able text book can be prepared. Hence the difficulty encountered by publishers also, whose frequent disappointment of work promised by busy practitioners and teachers is an oft reiterated complaint; against it there can be no guard so long as the present system of education lasts to encourage an unwise union of the professorial and the professional duties in a single individual.

In respect of weightier treatises on special subjects the same cannot be said. These are, as a rule, but the collected experience of men engaged in the business life of medicine; they embody the facts and observations noted from day to day, and when accumulated in sufficient amount there is required only the additional trouble of arrangement and deduction to make them ready for imparting information to others. In most instances works of this kind are eminently serviceable to the advanced student, and to men who are engaged in practice, and in not a few cases they are monuments at once of inductive skill and of permanently valuable research. This class of books has been well represented in the publications of the year.

Any complete enumeration of the books included under either of the two heads above described is obviously impossible in this place. It may be permissible, however, to indicate a few of those that have attracted particular attention; and of new works in this respect must be named the incomparable volume of abstracts of

papers read before the International Medical Congress. This consists of one bulky volume, in which are included short accounts of every memoir presented at the meetings, and each printed in the three official languages, English, French, and German. With it also, every member of the Congress received a catalogue of the temporary museum of pathological, &c., objects, arranged for the inspection of those who took part in the proceedings. Those two volumes, by themselves, form no unworthy memorial of the great World's Congress of 1881; but they shrink into insignificance before the *Transactions of the International Medical Congress*, which are officially announced to be ready for distribution on the last day of the present year, that is on Saturday next.

This great work consists of four volumes, and all the papers, speeches, &c., are printed in the language they were originally delivered in by their authors. Vol. I contains a List of Members, General Meetings, General Addresses, Museum, Anatomy, Physiology, Pathology, Materia Medica, and Pharmacology. Vol. II contains Medicine, Military Surgery and Medicine, and Surgery. Vol. III. includes Ophthalmology, Mental Diseases, and Diseases of the Skin, Throat, Ear, and Teeth. Vol. IV. contains Diseases of Children, Obstetric Medicine and Surgery, and State Medicine. Any criticism of this work would fail to convey an adequate view of its importance, or of its value: it is unique in every way, and will probably always remain unparalleled as a record of the greatest conference of medical men ever held.

The late Dr. Francis Sibson left behind him a large number of invaluable scientific monographs on physiological, anatomical, and clinical subjects, many of which have been of practical service as the basis of further study by their observers. Many, too, are of classical interest as, for instance, those relating to the position of the heart and other organs, &c., &c., scattered however among the pages of Society "Transactions," magazines, and reviews, a number of the most important were practically not available to the ordinary student. Recognising this fact Dr. William Ord, of St. Thomas's Hospital, has undertaken the task of collecting and editing the separate papers, which have been issued in four elegant and handsome volumes which reflect the greatest credit on editor and publisher alike. An interesting life of Dr. Sibson is prefixed to the first volume, from the perusal of which young and enthusiastic physicians will doubtless derive both hope and stimulus to the unflagging prosecution of professional and scientific work.

Dr. J. Milner Fothergill has published the first volume, dealing with "Indigestion and Biliousness" of a systematic treatise on the protean forms assumed by these diseases and gout, &c. The subject is treated from a strictly physiological standpoint, and while it is handled in the wonderfully attractive manner that lends such force to the author's style, it is also in the best sense a guide to the effectual treatment of the conditions dealt with in its pages. Dr. Fothergill's indefatigable pen has also been employed in the production of a number of invaluable papers contributed on various subjects, to the pages of contemporary journals, and to those, as well, of the *Medical Press and Circular*, one calling for special notice appeared in the *Practitioner* on the "Diagnosis of the Fatty Heart."

Messrs. Sampson Low and Co. have introduced during the year a new feature in medical publications by the issue of the first of an annual series of subscription works of standard authors. The arrangements made in connection with this provide for the production each year, in return for a fixed subscription of four guineas, of twelve volumes, and those for 1881 included several of the best known and most highly valued special treatises, such as Rosenthal on "Diseases of the Nervous System," Mundé on "Minor Gynæcological Questions," Trousseau's "Clinical Medicine," &c., &c. The scheme is a worthy one, and deserves to be successful.

A treatise on "Eczema and its Management," by Dr. Bulkeley, has recently appeared, which contains a vast amount of valuable and interesting information on the subject, and many original observations respecting the cause and nature of the complaint and its accompaniments.

Dr. MacLagan's work on "Rheumatism," Dr. Gross's on "Impotence," &c., Dr. Bartholow's on "Medical Electricity," Dr. Gower's on "Epilepsy," Mr. Barwell's on "Diseases of the Joint," and Mr. Treves's on "Scrofula," are all important publications of the present year.

Of the books written for students' use more particularly, we may make note of the following:—"Schematic Anatomy," just published, by W. P. Mears, M.B., is an attempt to lay the facts of anatomy in the form of diagrams and schemata before the learner, and so to aid him in appreciating the parts exposed during dissection, and remember them. It possesses a more than usual value in this connection. The "Index of Surgery," by Mr. Keetley, is a well-prepared and carefully-arranged synopsis of the chief points of importance in surgical science, and will doubtless become a favourite aid with students reading for examination. "The Diseases of Children," by Dr. Day, whose treatise on "Headaches" is now in a third edition, is an attempt to supply a much needed manual of instruction on the subject; it is, however, though ably compiled and full of sound practical information on many points, yet somewhat profusely illustrative on others, and hardly deals with the diseases of early infancy in a manner that is likely to afford assistance to the young practitioner in those most trying cases. The manual on the same subject by Dr. Ellis, a new edition of which has recently been published, is brought up abreast of recent advances, but it also fails to yield the sort of information that is frequently needed to help the due understanding and mode of treating complaints of very young children. These two works, however, are the most reliable the student can, in the present time, avail himself of. "The Diseases of Women" has been treated by Dr. A. W. Edis in a new work which is less bulky than many of the handbooks usually consulted. On "Throat Diseases" and "The Use of the Laryngoscope" we have contributions from the pens of Mr. Gordon Holmes, and the late Mr. W. Douglas Hemming.

From America announcements have been received of a new Encyclopedia of Surgery, among the contributors to which numerous well-known British and continental eminent surgeons will find a place. This promises to be the most complete and exhaustive treatise on the subject yet attempted, and will rival the similar English work

edited by Mr. Timothy Holmes, of which also a new edition is in preparation. The second volume of Dr. Agnew's admirable text book of surgery has appeared during the year, and the third and concluding volume is to be published shortly. New editions of several standard American books have been recently issued, such as "Flint's Medium," "Thomas's Diseases of Women," &c., &c.; of the regular publications mention may be made of the Transactions of the Clinical Society of London, the new volume of which contains several communications of particular interest; the annual "Reports of St. Bartholomew's, St. George's, and Guy's Hospitals;" Braithwaite's "Retrospect of Medicine;" "The American Journal of the Medical Sciences," an invaluable *resumé* of progress in the science and practice of the profession; and other works similar in character to them. A second edition, it should be added, of "Neale's Digest" is advertised as being among the publications for 1882, and the value possessed by the work will cause the announcement to be received with general satisfaction.

THE YEAR'S LOSSES.

Not a few of those who have long been familiar to medical men, either personally, or by the reputation they have achieved through their services to science, have passed away within the twelve months just concluded. The year has not, indeed, been so disastrously fatal in this respect as the one immediately preceding, when an unprecedented number of illustrious names were added to the roll of the honoured dead. But, notwithstanding, many of the younger and active members of the profession have paid the debt of Nature in 1881. The name of Dr. Archibald Billing had long ceased to be connected with the actual practice of medicine; but there are none among us, perhaps, who have not learnt to revere its owner for the value of the work achieved during the earlier period of his life. At the ripe old age of ninety-one, Dr. Billing entered into his rest, surrounded by the

members of his family to the third generation, and affectionately regretted by a large and appreciative circle of personal friends, to whom his hearty and kindly genial character had long endeared him.

Almost about the same time that Dr. Billing ceased to be, another former member of the staff of the London Hospital, and a *confrère* at one time of Dr. Billing, also died. Mr. James Luke, though very much junior in years to the venerable physician, had in his time done a vast amount of able and valuable work as a surgeon; and at the period of his death was consultant to the London, the hospital he had formerly served in the capacity of surgeon and lecturer. He had, however, retired for some years from active professional life, and living in the country, had to a great extent cut himself off from association with the working members of his profession. He died aged 74.

The University of Oxford sustained a heavy loss in May through the death of the Linacre Professor of Physiology—George Rolleston, M.D.—at an age but little over fifty years. Dr. Rolleston occupied a prominent position in all educational discussions, and was one of the most energetic members of the General Medical Council, in which he sat as representative for the University. He faithfully served in many other capacities. He had long suffered under ill-health, and his friends could only hope almost against hope for his complete restoration to strength. His death, however, created a void which will scarcely ever be filled up, and removed one who was under every circumstance devoted to maintaining the honour and dignity of the profession he did so much to adorn.

Other names crowd to the recollection as we reflect on the losses the year has seen. Thus Reynaud, Skoda, Otis, Greenhow, Hemming, Peatson, Bevan, &c., will all be remembered with a regretful feeling that much as they did in the time they were here, much more would have followed had they been longer spared.

Ireland.

INTRODUCTORY.

THE past year has been, as our readers well know, an eventful one, and one fraught with trouble and hardship to Irish doctors as well as the rest of the community. In the cities and among consultants the "hard times" have been severely felt, patients being comparatively scarce and generally impecunious, fees grudgingly promised, and payment long delayed; indeed, the metropolitan physicians and surgeons whose *clientelle* lay chiefly amongst the Irish landed classes, have been obliged to content themselves with earning prospective fees, booking them as income to be hoped for, but not to be enjoyed until the prospect brightens. In the Irish provinces the impecuniosity of patients has not been the cause of complaint, simply because the tenant farmers—paying no rent and being blessed with abundant crops—are just now the wealthiest part of the Irish community. Nevertheless, provincial practitioners have been placed, in all parts of Ireland, in a situation of much difficulty, being obliged to cultivate, with much diplomatic discretion, the art of "holding the candle to" one who should be nameless. In rabidly disaffected districts the local medical man has, in some instances, been obliged—willee-nillee—to join the current agitation and show himself as a supporter, in person and in pocket, of the popular side. In other places medical men, whose ideas of politics and of morality would not allow them to take this course, have been "boycotted" out of their income from private practice and tortured without mercy in their official capacity.

THE HEALTH OF IRELAND AND DUBLIN.

Happily Ireland has, within the year, been blessed by the advent of a health wave, which has materially altered the sanitary aspect of the country. The small-pox and fever epidemics, which, in the early part of 1880, bore so hardly upon the poorer classes and upon the medical officers who have professional charge of these classes, passed away in the early part of 1881, and, since then, there has been a uniform fall in the death-rate throughout Ireland. In Dublin, as will be recollected, the mortality of the year 1880 (chargeable in great measure against the abominably filthy state of the city and the utter incompetency of the Corporation of Dublin Health Committee) had reached a ratio so terrible that the usually lethargic citizens and always somnolent civic guardians of the public health were at length awakened to the presence of a death-rate which had no equivalent in any European city. Early in 1881 the Colleges of Physicians and Surgeons took joint action in the matter, and, after much deliberation, produced a public report on the subject which placed before the citizens for the first time the true causes of the extraordinary mortality of the city. Since then, under the improved administrative energy of Dr. Cameron, the Medical Officer of Health, a good deal has been done to

ameliorate the healthy state of the city. A vast number of poison-laden houses and cellar-dwellings have been closed against human habitation. Spaces are being cleared for the erection of artizans' dwellings, and, quite recently, the Dublin Town Council has arrived at a decision to spend a large sum of money on labourers' habitations under the Act which is in force in Glasgow. How far this increased sanitary vigilance of the Public Health Committee and its officers is to be credited with the present satisfactory condition of the health of Dublin cannot at present be decided, but it is beyond dispute that there has been a marked change for the better, the death-rate of the city having fallen, since this time last year, by nearly 30 per cent.

PUBLIC MEDICAL AFFAIRS.

The relation of public and parliamentary business to medical matters in Ireland within the year 1881 has been of considerable interest and importance. Apart from those legislative affairs which have special reference to education and Poor-law affairs, the profession has had to consider several Bills by which their interest was affected.

Mr. Gray's Bill for the

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES by the physician to the Sanitary Authority gave rise, as our readers know, to a very animated contest between the sanitarians and the profession. The Bill was introduced by Mr. Gray at the instance of certain ardent medical sanitarians, and the principle embodied in it, i.e., that the physician should be compelled under prosecution and penalty to send notice of all infectious cases to the City Sanitary Authority, was accepted by Mr. Gray in the belief—no doubt—that it would not be seriously objected to throughout Ireland. This anticipation was, however, falsified, for immediately, an active agitation to prevent the passing of the measure—in which movement we had pleasure in co-operating—was started by the Irish Medical Association, who sent a deputation to Dr. Lyons, M.P., to ask him to oppose the measure. Previously to this the Colleges of Physicians and Surgeons had given special consideration to the matter, and had passed resolutions acknowledging the propriety of notification of infectious disease in the abstract, but altogether disapproving of the proposed method of notification, i.e., by the attendant physician. Moreover, the Irish Medical Association held a special council meeting to consider the matter, and afterwards took a *plebiscite* of the profession in Dublin on the question, the vote then given being two to one against the proposal.

Subsequently a *plebiscite* of all Ireland was taken by the *Medical Press*, which revealed the fact that the medical profession was all but unanimous in its hostility to the measure. Under these circumstances Dr. Lyons felt himself called upon to act with decision against the Bill which, owing to the resolute opposition given to it by him,

was eventually withdrawn. In the autumn the subject was re-opened in the Public Health Section of the Social Science Congress with a negative result, and it now remains for settlement in the next session of Parliament. We hope, however, that the attitude assumed by the medical profession in Ireland will have convinced Mr. Gray, M.P., Mr. Hastings, M.P., and the sanitarians that, in Ireland, at least, the system of forcing the physician to notify to the sanitary authority will not work, and that, therefore, the Bill ought not to be re-introduced in its original form. There should be no difficulty in framing a system which would ensure that the sanitary authority shall be possessed of the desired information without sacrificing the medical profession to the necessity, and we hope to see a Bill which will serve the purpose introduced, with the approval and hearty co-operation of the doctors.

A CORONER'S BILL FOR IRELAND.

Was passed within the year after a limited consideration of the subject by a Select Committee of the House of Commons. It was introduced by Mr. Healy, M.P., and its objects were:—

1. To provide for payment of coroners by salary (at the rate of £2 per inquest for the average number of the last five years), instead of by fees as heretofore.
2. To restrict the polling at coroners' elections to one day instead of two as heretofore.
3. To increase the payment to poor witnesses, and for removal of the dead body.
4. To enable a disagreeing jury to be discharged and another empanelled.
5. To enable the coroner to take bail and recognizances.

On the introduction of this Bill the Irish Medical Association applied to be heard before the Select Committee, but—as no witnesses were heard—this request could not be granted. As therefore it seemed unlikely that any written communication would materially influence the Select Committee, the Association made no attempt to alter the existing law with reference to medical testimony at inquests. At present the law directs the coroner to call in “a duly qualified medical practitioner being at the time in actual practice at or near the place,” which definition is so vague that certain coroners are in the habit of bringing with them a friend from the other end of the county, and taking his evidence to the exclusion of the local practitioner who attended the deceased. It is to be regretted that the occasion could not be used to remedy this abuse, but, probably, it can be equally well dealt with by attacking the first typical case that arises first before the grand jury and then before the sitting judge. If once a fee wrongly paid were disallowed the precedent could be used to invalidate all similar payments in the future. A noteworthy episode in connection with this Bill was that the Irish College of Physicians, after solemn deliberation, actually pronounced its opinion that medical men should in future be excluded from the office of coroner, a theorem which evoked a warm protest from Dr. Lyons, M.P., and from the “Medical Press,” and which was treated by the Select Committee with significant silence.

CENSUS.

The year 1881 was “Census” year, and the adminis-

trative capacity of Dr. Grimshaw, the Registrar-General, was severely tested, and found fully equal to the tremendous task which devolved on his department. The result of the enumeration has, not yet, been fully published, but it has been ascertained that the ten years last past has resulted in a considerable reduction in the Irish population.

THE CORK PILOCARPINE HYPODERMIC INJECTION CASE.

The persecution of Dr. H. McNaughten Jones, of Cork, by a crack-brained schoolmaster named Crawford, who supposed that his child had died in the Cork Fever Hospital from a hypodermic injection of pilocarpine, administered by Dr. Jones, culminated within the past year in a trial for libel, in which the *British Medical Journal* was defendant, it having courageously, and not too strongly, censured the plaintiff for his outrageous proceedings. After a prolonged trial the case resulted technically in a “draw,” but the absolute innocence of Dr. Jones of either negligence or incapacity was so completely established, that his persecutor thought it wise to let the matter drop, paying, of course, the enormous cost which his vindictiveness had led him to incur. Since then the propriety of Dr. Jones's line of treatment has been fully vindicated by experience, and by its adoption by many of the leading physicians in Europe and America.

THE SOCIAL SCIENCE CONGRESS IN DUBLIN.

The Autumn of the year was enlivened by a very interesting and successful meeting of the Social Science Congress in Dublin.

Contrary to previous apprehension, the meeting was largely attended by extra-Hibernian members, and was hospitably received by the Dublin Statistical Society; the Royal College of Surgeons; the Royal Dublin Society; and the Lord Mayor. Trinity College opened its doors to the meeting, and thus gave special *clat* to the assembly of the Congress. The Public Health Section was presided over by Dr. Cameron, M.P., who not only displayed ability as its chairman, but delivered one of the most interesting addresses before the Congress at large, taking for his subject the recent investigations of M. Pasteur, and others upon “germ inoculation.” Under his presidency the Public Health Section debated with much warmth the Notification of Infectious Diseases; the State Supervision of Hospitals, and the mode of providing suitable Dwellings for Artizans and Labourers. During these debates a mass of information was elicited which amply repays consideration, and we entertain no doubt that the papers read will, before long, produce tangible legislative fruit.

ROYAL IRISH UNIVERSITY.

In the Irish collegiate world the great event of the year has been the completed organisation of the Royal Irish University and the contemporaneous disestablishment of the Queen's University. Although the Act for erecting the new University had passed Parliament in the previous year, there was some uncertainty whether it could be carried into effect, and the Queen's University hung on to the forlorn hope that some diplomatic change of front would save their *Alma Mater* from extinction. This hope proved illusory, for, though the Treasury vetoed the money estimates which had been prepared by the Senate

of the new University and reduced the sum asked for by nearly one-half, nevertheless, the organisation of the institution was completed, and the first matriculation examination was held on the 6th of December. At the last moment the Queen's Colleges succeeded in obtaining a concession in favour of their students, i.e., that such students should be allowed to take up the same position in the Royal University as they occupy in the Queen's.

The establishment of this great educational Institution appears to us to determine a crisis in the system of medical teaching in Ireland. Heretofore, the Irish Colleges of Physicians and Surgeons have been enabled to keep up the educational and monetary cost of their licenses because they had no serious competitor in the diploma market nearer than Scotland. Trinity College did not seriously interfere with them because of its determination to adhere to a full academic course in arts, and grant medical or surgical degrees to none but full A.B.'s. The Queen's University was, so to speak, "handicapped" in its race with the Colleges because of the requirement that each graduate should spend a year in Belfast, Cork, or Galway, which, to many students, was equivalent to a prohibition against their seeking the Medical Degree of the Q.U.I.

The Royal Irish University is, however, not restricted in the granting of its degrees by either of these requirements, for, while it accepts in without reservation students from all quarters, it will grant its medical and surgical licenses after surmountable examinations in arts. Moreover, it has adopted a curriculum and a scale of degree fees which will enable the student to obtain for £89 those licenses for which he now pays £160, and, as an additional attraction, it offers to the diligent student monstrous bribes in the way of scholarships and exhibitions.

We repeat that, against this competition, the exaggerated curriculum and diploma fees of the Colleges cannot stand, and it is only a question of time when both shall be materially curtailed.

IRISH EDUCATIONAL AFFAIRS.

The year 1881 may be noted as especially a reform year as regards medico-educational affairs, for in it the College of Surgeons—not too soon, but after prolonged deliberation—completed a new scheme of education and examination. The purpose of this scheme is to subdivide the student's work into the following grades of subjects (a) Preliminary Scientific; (b) Preparatory Professional; (c) Complete Professional; (d) Final and Practical; and thus to facilitate both his studies and his payments, while, at the same time, enlarging the range of his education and compelling him to work steadily from first to last through his studential career. We need not dwell upon the merits of this scheme with which most of our readers are already familiar. Inasmuch, as it peremptorily abolishes certain abuses which had for the last quarter of a century been profitably worked by a certain class of teachers, it was, of course, resisted by them with a great persistence, and with energy worthy of a better cause. At each step the scheme met with violent hostility at their hands, and on its final adoption a great effort, happily in vain, was made to prevent its adoption by the College of Surgeons. Its final promulgation and enforcement now only awaits the formal

approval of the Home Secretary, and we anticipate that long before our next *Annus Medicus* is written we shall be in a position to congratulate our readers on the accomplishment of the most valuable educational improvement of the current half century.

PROFESSOR HELMHOLTZ.

The College of Surgeons availed itself of the presence of Prof. Helmholtz in Dublin to confer on that very distinguished scientist the Honorary Fellowship of the College, an act which did as much honour to the College itself as the learned Professor.

THE DATE OF THE ANNUAL GENERAL MEETINGS OF THE FELLOWS

Was also changed, an alteration of greater importance than might appear at first sight, inasmuch as it will, we believe, induce a much larger contingent of the provincial Fellows to be present at the College assemblies than have heretofore been able to be present. Henceforth, the business meetings of the College will take place on the Saturday immediately preceding the first Monday in June, on which day the Council is annually elected.

PRELIMINARY EXAMINATION AND REGISTRATION.

This year, for the first time, the rule has been put in force that each student shall pass his preliminary examination and register with the Branch Medical Council as a medical student before he enters on his medical studies, requirements which will serve good purpose, inasmuch as they will prevent students holding over their general education examination until the end of their third year, and will also prevent school registrars from entering pupils in February and March for the lectures which commenced in the previous November—a practice which was as dishonest as it was usual.

IRISH POOR-LAW MEDICAL AFFAIRS.

This service—in which very many of our readers are deeply interested—has experienced not a little of the hardships which have arisen from the miserable state of Ireland during the past year. As we have said, fees have been scarce and "red-tickets" plentiful, and the work-houses being crowded much unremunerative labour has devolved upon the medical officers.

The Irish Medical Association was active during the Parliamentary Session in protecting medical interests, and working for those amendments of the Irish Medical Poor-law which are so much needed, but, in the perturbed state of the House of Commons, little could be accomplished.

SUPERANNUATION

has been the first subject of consideration, and we believe we may say that, by the efforts of the Association, it has been brought within a measurable distance of satisfactory settlement. A Bill has been drafted of which the following are the chief provisions.

1. That the pension shall be the right of the Poor Law Medical Officer, and that it shall no longer be possible for the guardians to refuse it, or curtail it.
2. That the Poor Law Medical Service shall rank for pension as a branch of the Civil Service, and receive superannuation according to the Civil Service Scale, i.e., ten-sixtieths of his total salary and emoluments, at the end of two years service, and one-sixtieth for each subsequent year of service until the pension amounts to two-thirds of these

emoluments, after which there shall be no further increase. 3. That in the case of Medical Officers ten years be added to the period of actual service, and the pension computed on this basis. 4. That a Medical Officer incapacitated from duty by old age (60 year) or infirmity of mind or body be entitled to the two third pension—irrespective of his period of service. This scale of pension had been adopted in 1880 by the English Local Government Board, and has within the last few weeks been also adopted by the Irish Board, but in both countries the grant of a pension is still discretionary and it is to the removal of this option that the efforts of the Irish Medical Association will be chiefly directed. During the last parliamentary session a deputation from the Association waited on Mr. Forster, the Chief Secretary, in the hope of obtaining Government approval for their Bill. And, though it was obviously out of the question that the Chief Secretary could undertake to force any measure of the sort through the hopelessly obstructed parliament of last session, nevertheless, his reply was favourable to the measure, and he promised to look with favour on the Bill if it should be introduced by a private member. The Irish Medical Association is now preparing for its presentation to the House in February, but a serious difficulty stands in the way, which, if not removed, may seriously impede progress. The union clerks, and other non-medical officers, are not willing that the case of the medical officers should be dealt with without including all union officers, and they are not disposed to accept a measure which will be suitable to medical officers. The non-medical officers make a strong point of being able to retire from office early in life and robust in health, and they do not regard it as of vital importance that the guardians should cease to have power of refusal.

It is to be earnestly hoped, in the interests of all parties, that there will be no antagonism between the medical and non-medical officers, for—if there be—it is quite certain that neither party will gain anything. The Irish Medical Association has, after careful thought, decided to proceed with the Bill for medical officers alone, because they are convinced that a measure to include every union officer in Ireland would not be tolerated at present. It would, we think, be wise for the non-medical officers to encourage the smallest measure, and thus establish a precedent for the larger scheme which they themselves desire.

With reference to the subject of superannuation, an important return, moved for by Mr. Meldon, M.P., in 1880, was presented in 1881. It showed the applications for pensions made, distinguishing those granted from those refused, and setting forth the reason (if any) for refusal. From this return it appeared that only eleven medical officers had been refused since the passing of the Superannuation Act in 1869. This is apparently a small proportion of refusals, but it will be at once seen that the number of instances in which applications were rejected is no measure whatever of the extent of the grievance which exists, because it takes no note of those cases (the great majority) in which the medical officer was not refused simply because he dare not think of asking. The return, indeed, contains only those cases in which the medical officer was pretty confident that his request would be granted, but was disappointed in his hope.

THE LUNACY LAW ASSIMILATION BILL,

Which had been introduced by Lord O'Hagan in the Upper House in 1880, was taken up in the House of Commons by Mr. Litton, M.P., in 1881. It provides that the English law shall be extended to Ireland, which allows of harmless lunatics being "boarded out" with their relatives or caretakers, payment for their maintenance being made by the lunacy authorities. In order to their better care, it is also provided that the dispensary medical officer of the district in which they live, shall visit them frequently, and make report of their condition, and shall receive a fee of half-crown for each such visit. This Bill the Irish Medical Association supported by petition in the House of Commons, but sought to have introduced into it a clause to make better provision for superannuating the medical officers of lunatic asylums, who have long remained in a very unfair position in this respect. In consequence of the obstruction to business in the House of Commons, the Bill was eventually withdrawn, and, as Mr. Little is now promoted to a land judgeship, it will be necessary for some other member to take up the measure, which certainly deserves to pass. There are, however, some persons of influence by whom the measure is not looked on with favour. They hold that "boarding out" is all wrong, and that all lunatics should be in asylums; but as the Irish lunatic population had outgrown the accommodation of the asylums, and the resources of the Lunacy Department, it was proposed to appropriate workhouses, which are now little used to the purpose of auxiliary asylums. This scheme was, however, successfully resisted by the guardians of such unions, because they did not choose to be disestablished and deprived of the honour (?) of the P. L. G.; and thus Lord O'Hagan's Bill became necessary. We hope to see it made law in next Session.

RE-VACCINATION FEES.

An important issue was fought out within the year on behalf of the dispensary medical officers by the Irish Medical Association. The Vaccination Amendment Bill of 1879, which had been introduced at the instance of the Association, and passed by their influence, provided *inter alia* that "The Board of Guardians shall pay to every Medical Officer for every person successfully vaccinated, or for every person re-vaccinated by him," a fee of 2s. Small-pox having broken out in the Fintona District of the Omagh Union, the medical officer—Dr. Duncan—re-vaccinated a large number of persons, some of whom developed a vesicle and some did not. For the whole number he sent in his bill to the guardians, who—acting on the advice of the Local Government Board—refused to pay for any re-vaccination which was not "successful"—i.e., which did not produce a vesicle. This reading of the words above quoted was directly at variance, not only with the intention of the framers of the Act, but with its plain meaning; and the Irish Medical Association, being advised by counsel that the Local Government Board's interpretation of the Act was entirely wrong, took up the case. It was argued twice before the Queen's Bench in Dublin, and the unanimous judgment of the Court given in favour of the Association. It is, indeed, difficult to

understand how the legal adviser of the L. G. B. could have encouraged the Omagh guardians to contest the case. It is, however, satisfactory that the right of vaccinators to be paid for *all* re-vaccinations has been established beyond further dispute.

RED TICKETS.

The intention of the Association to deal with the abuses of red tickets by a Bill in Parliament could not be carried into effect last year, in consequence of the block to business in the House of Commons. The Bill, framed by the Association, simply improves the method of cancelling tickets by enabling the medical officer to apply to the next Petty Sessions, instead of waiting three or four months for a meeting of the Committee which, probably, is unwilling to discredit a ticket issued by one of their number. The Bill also gives the medical officer the power to sue either the issuer (wilfully) of an improper ticket, or the recipient thereof, if it be obtained by false representation.

We suppose this most necessary and just measure will have to stand aside until the superannuation question is settled, but we hope no opportunity will be lost of dealing with a condition of things which greatly burthens the dispensary medical officer and robs him of his just earnings.

UNION DRUGS.

The Local Government Board for Ireland made one step in the direction of the much-needed reform of the notorious drug contract system. In the autumn of the year, the old drug list, upon which estimates have been prepared for the last thirty years, was withdrawn, and a new one issued, which omitted a multitude of obsolete medicines, and introduced a few of the more modern therapeutic agents which, hitherto, the medical officer has been obliged to order as extras at an enormous price. One of the features of the new list is that it authorises the use of coated ready-made pills, a change which will not only relieve the medical officer of much pharmacy work, but will give him new confidence in the medicine he prescribes, and will strike a blow at the old system of supplying fraudulent drugs at monstrous prices for the use of the sick-poor. We earnestly hope that the Local Government Board will not be content with this small measure of drug reform, but will, once and for all, purge the medical charities of the disgrace which the drug contract system has so long brought upon it.

POOR-LAW WIDOW AND ORPHAN'S FUND.

The establishment of a Poor Law Widow and Orphans Fund which has for some years been in contemplation has advanced a step within the year. The Irish Medical Association has taken the actuarial advice of Mr. Hancock on the subject, and has taken as a model the scheme under which a similar fund is worked in connection with the church of Ireland. This scheme has by the experience of several years since its establishment, proved a success, and the Association has thought it well to frame its plans as closely as possible upon data which have been tried and found to be sound. The principles of their scheme are as follows:—*a.* That every new entrant of the Poor Law Medical Service shall be compelled to contribute to the fund. *b.* That those now in office be permitted to

do so—the amount of their contribution being fixed upon an actuarial examination of their particular case. *c.* That the contribution be a quarterly deduction from salary, collected by the Fund Council from the clerk of each Union and debited by him to the individual officer. *d.* That a deduction of £5 a year will be sufficient to provide £20 for the widow and £10 for each child under twenty-one, payable after the death of the contributor.

This scheme was submitted to the Local Government Board by a deputation of the Committee of the Association, and was favourably received by them. Since then Mr. Hancock has examined the proposal and expressed his belief in its financial soundness, and it may be expected that, on the first suitable opportunity, a Bill will be introduced into Parliament to make it law.

RECENT APPOINTMENTS.

In the early part of the year the office of physician to the Queen in Ireland fell vacant by the death of Dr. Hudson, and to it Dr. Benjamin George M'Dowel, Physician to the Whitworth and Hardwick Hospitals, and one of the Court of Examiners of the Irish College of Surgeons, was appointed.

The office of Crown Representative for Ireland in the General Medical Council had been occupied by Dr. Mc Clintock after the decease of Dr. Hudson. Again the appointment fell vacant in November last by the lamented death of Dr. McClintock, and to it Dr. Lyons, M.P., has been recently elected, a choice which was fully expected, and generally affirmed.

In the College of Surgeons, Dr. Chaplin, of Kildare, succeeded Dr. McClintock in the presidency, while Dr. Barton, of the Adelaide Hospital, became vice-president, and Dr. Bennett replaced Dr. Nixon as a member of the council.

In the College of Physicians, Dr. George Johnston still holds the presidential chair, having consented to retain office for another year in consequence of the much regretted death of Dr. Hayden, who would otherwise have been chosen President.

The King's Professorship of Materia Medica in the School of Physic which is in the gift of the Fellows of the College and which has been held for many years by Dr. Aquilla Smith, was vacated by him, and his son Dr. Walter Smith, Physician to the Adelaide Hospital was elected. This appointment involved the transfer of Dr. W. Smith to Sir Patrick Dun's Hospital, and his place at the Adelaide was filled by the appointment of Dr. Wallace Beatty.

The office of Consulting Physician to the Rotunda Hospital, vacant by the death of Dr. Hudson, was the subject of a contest which ended in the election of Dr. Little, Professor of Medicine in the College of Surgeons.

IRISH MEDICAL LITERATURE.

Our columns have, during 1881, contained the following contributions from Irish authors: Mr. Barton, on Excision of the Wrist; Dr. Franks, on Acute Laryngitis; Dr. Thomson, on Excision of the Tongue; Mr. Knott, on Colles's Fracture; Mr. Wheeler, on the Merits and Demerits of Antiseptic Treatment; Dr. Quinlan, on Paracentesis of the Bladder; Dr. Bennett, on Osteotomy; Dr. Nixon, on MacEwen's Operation; Dr. Cameron, on the Provision of

Labourers' Dwellings; Dr. Finney, on Herpes; Mr. Richardson, on Vertebral Caries; Mr. McCarthy, on Skin Grafting. Numerous clinical records of interests were also contributed by Drs. Mayne, Ormsby, Young, O'Grady, and other esteemed contributors.

OBITUARY.

Our record of Irish medical events must close with the melancholy record of the deaths of many members of the profession of distinction. Amongst those most worthy of memory by their brethren we must name Dr. Christopher Fleming, for many years Surgeon to Steeven's Hospital, and Chairman of the Court of Examiners of the College of Surgeons; Dr. Hayden, Professor of Anatomy and Physiology in the Catholic University School; Dr. McClintock,

Ex-Master of the Rotunda, and late President of the College of Surgeons; Dr. Alexander Carte, Curator of the Natural History Museum, under the Science and Art Department, and some time Curator of the College of Surgeons; Dr. Hamilton Labatt, Dr. Edward Peele, Dr. Corigan, Physician to St. Vincent's Hospital, Dr. Sydney Murdoch, of Dublin, Dr. Gabriel Stokes, of Mullingar, Dr. Little, of Lifford, Dr. Rawson, of Carlow, Dr. Abbott, of Bray, Dr. Bernard, of Dundrum, Dr. Jencken, of Kingstown, and Dr. Willes.

The Retrospect of the year is, as far as Ireland is concerned, not a happy one, and we must only look forward to a time—not yet in view—when we may be able to give a report of greater prosperity and better progress for our Irish brethren.

Scotland.

INTRODUCTORY.

ANOTHER year, with furtive step, is about to be placed to our account. It is, as the poet says, "the time that exalts the soul to solemn thoughts and heavenly rousing;" and we are all confronted with the momentous reflection that we are one goal nearer the eternal solution of that sublime enigma which prostrates intelligence, and before which reason stands appalled. As is our wont we dedicate this, the last number of the year, to a retrospective summary of occurrences and movements touching our profession, and to the pious duty of recording losses sustained by our calling during the past twelve months. These, we regret to say, have been both numerous and unexpected.

Many questions deeply affecting the medical profession have been agitated during 1881. Paramount in importance is the one at present engaging the attention of a Royal Commission, that of

MEDICAL REFORM.

Quite recently the general question of University reform was largely discussed in Scotland; the *status quo*, being on the one hand defended by interested parties, the Scotch professors, and the urgency of reform being advocated widely by such as maintain that the present position and powers of the Universities are not in harmony with the progressive spirit of the age, and are educationally subversive of the best interests of the public, those of learning. It was made sufficiently manifest in the course of this discussion, that with the monopolies at present possessed by the Universities, widespread dissatisfaction exists among all intelligent people. Early in November an influential deputation waited upon Lord Rosebery, Under Secretary of State for the Home Department, and the Lord Advocate, urging the appointment of an Executive Commission to inquire into the state of the Universities of Scotland. This deputation had in view more especially reforms in the Arts' Departments; but it is sincerely to be hoped that in any such inquiry will be many anomalies touching the teaching of medicine will not be passed over. In these columns we quite recently referred to the state of matters at the University of Glasgow; how classes and expenses had enormously increased during the past twenty years, while the curriculum of study remained the same; and how disadvantageously extra-mural teachers were placed in having as competitors teachers who also examined and qualified. So strikingly are these shown in the subjoined comparison columns that further reference to the subject is, at present, superfluous.

Curriculum of study at Glasgow, 1862.

	£	s.	d.
Anatomy, 1 course	3	3	0
Practical anatomy, 1 course	1	11	6
Anatomical demonstrations, 1 course	2	2	0
Chemistry, 1 course	3	3	0
Practical chemistry	1	11	6
Chemical laboratory, optional			
Physiology, 1 course	3	3	0
Surgery, 1 course	3	3	0
Practice of physic, 1 course	3	3	0
Materia medica, 1 course	3	3	0
(Second course succeeding session, optional. Taken by those who could afford it to conciliate the professor, and facilitate the passing of degree examination).			
Medical jurisprudence, 1 course	3	3	0
Midwifery, 1 course	3	3	0
Botany, 1 course	3	3	0
Perpetual hospital ticket, including clinical lectures on surgery and medicine	12	12	0

Total thirteen classes at a cost of 46 4 0

Curriculum of study at Glasgow, 1881.

	£	s.	d.
Anatomy, 3 courses	11	11	
Chemistry, 2 courses	6	6	
Botany, 2 courses	5	5	
Physiology, 2 courses	6	6	
Zoology, 2 courses	5	5

Medicine, 2 courses	5	5	
(Chiefly lectures on diagnosis)			
Hospital and clinical medicine and surgery	21	0	
Pathology, 2 courses	5	5	
Surgery	5	5	
Operative surgery	2	2	
Materia medica, 2 courses	5	5	
Practical materia medica	3	3	

Total twenty-one classes at a cost of 87 1

SCOTCH MEDICAL CHARITIES.

By an immense number of superficial thinkers it is considered that there is no limit to every form of charity. By the more thoughtful, and certainly not the least charitably disposed, unostentatious charity is regarded as an agent of moral depravity and social demoralisation. That medical charity has far exceeded the legitimate requirements of our large communities, and is operating in the direction indicated, is admitted by all unprejudiced men whose opinions are worthy of being attended to. The "survival of the fittest" (though it is by no means the most worthy medical men who survive in large communities, as the proportion of fools to sensible people is so unequal): we say the theory expressed in this now celebrated law is well brought out in the proportion of medical practitioners to a given community. Speaking generally, and with a nearness to accuracy, the proportion in which medical men are maintained in any degree of comfort by a population, may be put down at one medical man for every thousand of the community. In 1851 the population of Glasgow was 255,000, and, on the basis submitted, the city should comfortably support 255 medical men. The actual number was 231 medical men. In 1851 there was but one Public General Hospital, the Royal Infirmary, with 200 beds for medical and

surgical cases, and 120 beds for fever cases. In 1861 the population had increased to 329,000, and the number of medical practitioners had fallen to 226, instead of, as ought to be the case, according to our belief, 329. In 1881, with a population of over 500,000, there are but 294 practitioners; but 63 practitioners more than in 1851 *with a population about doubled*; but in 1881 there must be over 150,000 of the community in receipt of *gratis* medical aid, while in 1851 it was merely nominal, there being but 200 beds available for medical and surgical cases, and only the very poorest taking and receiving medical advice at the dispensaries. If we deduct the 150,000 which we believe to be in receipt of medical aid at our infirmaries, &c., and those who are in medical clubs, which may safely be put down at 50,000, we come very near the proportion which we believe the community is able to support, 300; *while the actual number is 294*. Is it not thus demonstrated unmistakably, that the profession is robbed by this excessive charity? But what is the result on the community? It leads to improvidence, and the feeling of self-respect, which ought to be encouraged among the middle, among all classes—is unquestionably undermined. In 1881 people frequent hospitals whose position in society is such that they would never have dreamt of doing the same in 1851, encouraged as they are to go there by the directors, in order that they may appeal with a larger bill of woe to a stupid and unthinking public. Nay more, it is alleged that the “better classes” who frequent hospitals are followed to their houses as by sleuth hounds, by the starving acolytes of the senior physicians and surgeons. But what is the effect on the hospitals themselves? It is this. They have outgrown all reasonable dimensions and necessities; the public are beginning to find the demands for their support intolerable; and their directors are engaged in a continual struggle to find the means of maintenance. In the face of all this Glasgow is threatened with a third hospital, and by a mental twist, which is difficult to reconcile with ordinary intelligence, the directors of the Royal Infirmary regard the scheme as “a laudable desire!” In the same breath they appeal “to those of both classes who may not have considered or realised to any extent the particular and pressing claims of hospitals, that they will come to the aid of the directors with a portion of the means with which a kind Providence has favoured them.” What has the struggling doctor to say to this? He doubtless begins to experience in Patriarchal anguish that Providence seems to be on the side of dealers in brass and iron, and that, consequently, so far as he is concerned, the struggle is far from being a fair one. We would suggest, in the interests of the profession and the public, that it is high time to inquire into this gross abuse, and that the “provident system” of medical relief be substituted, where possible, for the indiscriminate eleemosynary aid at present so wantonly extended in all quarters.

THE EDINBURGH SCHOOL.

ROYAL COLLEGE OF SURGEONS.—Mr. Imlach has been elected, for the third year, president of this ancient corporation. It is understood that the object of this election is to keep the seat warm for Prof. Turner who, while

acting on the Royal Commission, was not eligible for election. If another president than Mr. Imlach were elected, Prof. Turner could not be elected for two years, and this would be regarded as unfortunate in the highest degree by the opponents of medical reform, as by the election of Prof. Turner to the presidentship, the University influence in the College will be strengthened, and a desire for teaching by it be thus more effectually repressed. During the past year the College has been fairly successful in a commercial aspect. It received £1,025 for its Fellowship Qualification; and from the Double Qualification the sum of £1,150. Its total revenue amounted to £3,659 2s. 7d. It has increased the salaries of its treasurer and clerk to £100, and gifted £100 to the library fund. At a recent dinner of the Edinburgh Merchant Company, Mr. Imlach made a speech in which he openly avowed his hostility against Medical Reform, which, he alleged, “if carried into effect, would deprive them of their privileges of licensing candidates for admission into the profession.” It is well understood that the recent rigour of examination in Edinburgh, and the existence of the Royal Commission, stand in the relation of cause and effect. Mr. MacNair, a Leith Parochial Medical Officer, was recently elected an examiner at this College.

Dr. Haldane was elected, for the third year, likewise, President of the Royal College of Physicians, because being in the Medical Council, he can perform the not most enlightened nor dignified duty of a “drag.” Dr. Douglas MacLagan is regarded as the probable president for next year.

At the UNIVERSITY OF EDINBURGH certain changes have taken place in the teaching staff. To the Chair of Pathology, which became vacant by the lamented death of Dr. Saunders, Dr. Greenfield, of London, was appointed, very much to the regret and disappointment of a large number of Edinburgh graduates, who maintained that the paramount claims of Dr. J. D. Hamilton had been very unjustly overlooked. Personally, no objection is taken to Dr. Greenfield. It is noted with interest that, like all his Scotch professional *confrères*, he has glided happily and promptly into the principle of farming his chair to the best advantage to himself. Not having been to Glasgow to study this branch of political economy the ability displayed by Dr. Greenfield in this department is truly presumptive of intellectual keenness. The learned Professor finds that it is impossible for him to recommend a text-book in pathology, no English work being equal to the knowledge required. Hence, the most copious notes possible must be taken. Of course, Prof. Greenfield has got a practical class, and both his classes are full to overflowing. We regret that Dr. Hamilton does not lecture this winter, finding the manner in which he is handicapped by the University authorities so discouraging. We trust the time is not far distant when this cannot be said in such cases. The Practical Anatomy class numbers about 600, and it is thus easy to understand that “subjects” are scarce and the demonstrators, for they must be paid, too few. Minto-House Anatomy Class continues to hold its own, while that of Surgeon's Hall is small as usual.

A discussion has been going on as to the composition of the medical school. The colleges repudiate all connec-

tion with the extra-mural schools, at the same time drawing fees from candidates for the lectureships. Some six years ago we understand a committee of extra-mural lecturers was appointed to take into consideration the advisability of applying for a charter of incorporation for the extra-mural school, the late Dr. Handyside being chairman. Counsel's opinion was taken, but the justly aspiring lecturers were given to understand that the University was prepared to spend any amount of money to crush so impious a scheme. It was certainly very questionable whether the University had any right to spend public money in any such attempt. It is somewhat difficult to see why the Edinburgh Colleges should not support the school, and spend some of their great wealth in thus putting it on a better footing. It seems to us to be the renown of the school, and not the value of the college licenses, which attracts students to Edinburgh. At a recent meeting of the University Court the following regulations, regarding the recognition of courses of instruction given by extra-academical lecturers, as qualifying for graduation in medicine, were adopted:—

"1. Every applicant for recognition shall furnish for the information of the authorities of the University:—1, A syllabus of his course of lectures; 2, a statement of the number of lectures, and of the number of written or oral examinations in the course; 3, a statement of his opportunities of studying the subject in which he desires recognition, and of the length of time devoted thereto; 4, a statement of the experience he has had in teaching the subject; 5, a note of the titles of his contributions to the science of the subject; 6, a statement as to whether his course or courses of instruction have been already recognised by any University or other examining body, and if so, what means were adopted for ascertaining his qualifications for teaching.

"2. In the case of every applicant for recognition residing in Edinburgh or its neighbourhood, an inspection shall be made of his teaching appliances and accommodation for teaching.

"3. Every recognised extra-academical lecturer shall annually furnish the University with the information regarding his course or courses which is required from the University Professors as to—(1) The number of students attending the recognised course or courses of instruction; (2) the number of meetings for ordinary class work in the session, and in each week, thereof, excluding meetings which fall under the next head; (3) the number of special written examinations; (4) the system of conducting the ordinary class work, and the number of meetings devoted to each kind of work.

"4. In the event of an extra-academical lecturer removing from the premises or building occupied by him for teaching a recognised course, such lecturer shall be required to intimate his removal to the University Court, in order that the Court may have an opportunity of considering whether the accommodation in the building to which he has removed is adapted for the purpose of teaching the subject in which he was recognised.

"5. When the application is made for the recognition of a course taught by two or more lecturers, in conjunction information shall be given of the share to be taken by each lecturer in such a conjoined course; and the recognition

of such conjoined courses, and of each of the lecturers recognised as teachers of a conjoined course, shall, *ipso facto*, terminate should one or more of the lecturers cease to conduct the course, or should any material change be made in the share of each lecturer in the teaching of the conjoined course.

"6. The recognition of any lecturer who has ceased for the period of two consecutive sessions to teach the subject on which he was recognised, shall, *ipso facto*, terminate."

The object of these regulations is certainly one of hostility against the school.

Professor Wyville Thomson having resigned the chair of Natural History, candidates are already spoken of, among them may be mentioned Professor Alleyne Nicholson who has the greatest claim on the office, Dr. Young, of Glasgow, Ray Lankester, Professor Huxley, Professor Oarus, and Mr. Patrick Geddis. Dr. Nicholson is a distinguished graduate of the University, and it cannot well afford to repeat the mistake and injustice which it visited on Dr. Hamilton.

THE GLASGOW MEDICAL SCHOOL.

The number of students continues to increase at the University of Glasgow, to an extent incompatible with efficient teaching. The matriculations for the present Session amount to a total of 2,316, out of which 624 belong to the Faculty of Medicine; and Arts and Medicine 25. Last session the matriculations in medicine were 557, and in the previous year 539. It is extremely probable that this gradual increase in the number of medical students is stimulated by the dread of impending change, as resulting from the Royal Commission, in the matter of Medical education and qualification, and possibly also the dread of an increased expense, which, in all truth, is high enough at present. In quite a recent number we pointed out the shameful growth of supernumerary classes at the Scotch universities, the injustice thus done to the student, and the widespread dissatisfaction that exists thereanent in the entire profession. The hope is indulged that we are on the eve of radical changes in the matter of medical education, which, by restricting the mischievous monopoly possessed by the universities, will give a beneficial stimulus to medical education.

The popularity of the Faculty of Physicians and Surgeons continues. During the year the number of candidates who presented themselves for the preliminary examination was 275, and of this considerable number but 76 passed. At the first professional examination 51 passed, and 55 were rejected—total 106; at the second professional examination 63 passed, and 55 were rejected—total 118. It is thus evident that as large, if not a larger proportion, is rejected by the Faculty, as by any of the other examining bodies; and that its claim to existence are undoubtedly as strong as those of its competing Corporations. To the Board of Examiners, a new examiner, Dr. Hugh Miller, was elected this year. This is a step in the right direction. Some of the present examiners have held office for nearly thirty years, and the warmth of their affection for the Faculty is easily explained on very evident principles of political economy. So strongly is the desire for centralisation in this respect manifested, that, not satisfied with the powers possessed at the University, and the benefits accru-

ing therefrom, certain of the University professors are also examiners at the Faculty. It is difficult to avoid the conclusion that this either evinces a spirit which had better not be distinctly characterised, or a sad want of capacity on the part of many Fellows of Faculty. Further change in the Board of Examiners at the Faculty is urgently demanded.

Anderson's College is fairly well attended. At this School students, if at all attentive themselves, cannot fail to become well grounded in the all-important subject of anatomy. We understand that the teaching of Drs. Gemmell and Wallace, the two most recently appointed lecturers, is much appreciated by the students.

At the Royal Infirmary School certain changes have also taken place, and by the well-wishers of the School it is deplored that the recent appointments do not seem of a nature likely to advance the teaching reputation of the School. It is perfectly absurd to make men with an infinitesimal practical acquaintance with their profession, teachers of any branch whatever. By a dexterous *coup* on the part of Dr. Wood Smith, Dr. Wallace Anderson lectures on the Practice of Physic; Mr. Glaister is now Lecturer on Medical Jurisprudence, vice Dr. William McEwen, who in turn lectures on Surgery, vice Dr. Cameron, removed to the Western Infirmary. The class of Physiology at this School should be looked after compassionately.

The Western Medical School is still struggling for existence, and, considering its youth, shows signs of vigorous vitality. The versatility of the teachers is one feature which strikes us. Dr. J. M. Milne lectures on Chemistry; Mr. A. E. Mayland, lately of Guy's Hospital on Anatomy; (Mr. Mayland has been driven to Northern latitudes by the delusive advertisement which the managers of the Royal Infirmary cause yearly to appear). Dr. Neil Carmichael, on this occasion, expounds the mysteries of *Materia Medica*, and Dr. Ebenezer Duncan those of Medical Jurisprudence, and Public Health.

The vacancy caused by the lamented death of Dr. Foulis has been filled by Dr. D. Newman's appointment as pathologist and lecturer on Pathology at the Royal Infirmary; and Dr. W. J. Fleming has been appointed Dispensary Surgeon to the same Institution.

ABERDEEN MEDICAL SCHOOL.

It is gratifying to be able to record that no deaths occurred in the Aberdeen profession during the year, and that no changes have taken place in the professoriate. Dr. Simpson was appointed medical officer of health in succession to Dr. F. Ogston, sen. It says very little for the inducements offered by the medical profession, that several candidates of high professional standing were willing to give their entire time to the duties of this office, for the very modest remuneration of £300 per annum. Dr. Hall was appointed assistant surgeon to the Royal Infirmary.

SCOTCH MEDICAL SOCIETIES.

At the Edinburgh Medico-Chirurgical Society several papers of importance were read during the year. Of these may be noted Dr. Byrom Bramwell's paper on the Differential Diagnosis of Paralysis, accompanied as it was by a beautiful series of microscopical preparations and drawings; Dr. Grainger Stewart's paper on Paralysis of the Hands and Feet from Disease of Nerves; Dr. Hamil-

ton's paper on the Physics of Inflammation; Professor Fraser's paper on the Failure of Salicin and Salicylate of Soda in Acute Rheumatism accompanied with Inflammation of the Genito-Urinary Mucous Membrane; Dr. James's remarkably able and original paper on the Reflex Inhibitory Centre Theory; and Dr. Cadell's paper on the Treatment of Syphilia, which Dr. A. Gray properly observed should have been entitled on the Non-Mercurial Treatment of Syphilia. It is noteworthy that even in Edinburgh where anti-mercurial tendencies run so high, testimony to the efficacy of mercury in the cure of certain forms of syphilia was borne by such men as Mr. Joseph Bell, Dr. Argyll Robertson, and Dr. Miller. A vast amount of painstaking work was accomplished in connection with the *Edinburgh Obstetrical Society*. Dr. Halliday Croom in his paper on the Systematic Employment of Antiseptics in Midwifery, evinced a more than usual faith in carbolic acid. Dr. Hart contributed a very valuable paper on the Shape of the Empty Female Bladder. Dr. Bell, of Glasgow, read his peculiar paper on an Improved Method of Treating Uterine Displacements, regarding which, the President, Dr. Angus Macdonald, cautiously observed "that he must be held as distinctly guarding himself against being in agreement with a great part of what Dr. Bell had advanced in his paper." Like most of the papers read at the Edinburgh societies this one was also published in the *Edinburgh Medical Journal* and such was its peculiarity that we felt called upon to notice it in the form of a "leader" during the year. We scarcely think it likely that this respectable journal will risk its well earned reputation soon again by the publication of such primitive English and such questionable science. A celebrated Frenchman, Turgot, long ago remarked "moins on sait, moins on doute . . . quand les hommes sont ignorans il est aisé de tout savoir." Dr. William Turner, of Glasgow, read a valuable paper on a Case of Delivery by "the Breech" through a greatly Narrowed Flat Rachitic Pelvis. Dr. Angus Macdonald Two Cases of Chronic Inversion of the Uterus; Dr. Chas. Bell on Extra-Uterine Conception.

At the *Glasgow Medico-Chirurgical Society*, the papers did not attain to the usual level of interest or intelligence. The Society is, indeed, not so well attended as it used to be. This seems due to two circumstances: the existence of the *Pathological Society*, which is chiefly composed of young men, who accordingly "discover" much; and of the *Philosophical Society*, composed of the *nouveaux riches* tradesmen of the city, and which is consequently resorted to by medical men as a better advertising arena. Among the papers read at the Medico-Chirurgical may be mentioned Dr. Kirk's on a Case of Poisoning by Carbolic Acid, Dr. Murdoch Cameron's on Uterine Flexions; Dr. Lyon's on Axis Traction Forceps; and Dr. William L. Reid's paper on the Use of Antiseptics in Obstetrics and Gynecology. This paper was a *réchauffé* of a German one, and seemed to create a good deal of interest, doubtless, owing to the originality of many of its suggestions. The obstetrician himself was to be rendered "aseptic;" his instruments, clothes, hands, hair, eye-brows, &c., and the *homunculus* was to be ushered into a sinful and sorrowful world purified by having passed (if he did not happen to be choked) through a cloud of carbolic acid

spray! Some profane medical sceptics of the old-school in Glasgow, alleged that, doubtless, we were on the eve of being recommended to micturate under the spray! Dr. Reid's paper does not seem to have made a lasting impression on scientific thought. This Society had also under consideration the much agitated question of Vivisection, when the following resolution was moved by the President, and unanimously adopted "That it is the opinion of this Society that experiments on animals are necessary for the advance of medicine, and that no obstacles should be thrown in the way of competent men performing such experiments. Further that this Society strongly deprecates the infliction of unnecessary pain, and would support any law which would check this without obstructing competent observers, as the present law does."

LITERATURE.

Few new books have issued from the press in Scotland, or belonging to Scotland, during the past year. The fifth edition of the "Syllabus of Materia Medica, for the use of Students, Teachers, and Practitioners, based on the Relative Value of Articles and Preparations, in the British Pharmacopœia," by Dr. Harvey and Dr. Davidson was published by Lewis. The third edition of Dr. Charteris's little manual published by Churchill appeared; and also Dr. Robert Bell on "Diphtheria," which philologically, philosophically, and psychologically is indeed a study. The *Edinburgh Medical Journal* continues to maintain on the whole, its high standard of excellence. The *Glasgow Medical Journal* we believe drags out its tabetic existence. Still it is much to be regretted that with such a field as Glasgow at command, a journal acceptable to the entire profession, should not be maintained in this city. The extreme mediocrity of the present one, and the small amount of support extended to it are due to the fact that this journal is conducted on a narrow basis, and under assumed pretensions to which the profession in Glasgow do well to refuse to bow the knee.

OBITUARY.

DURING the past year many and well-known members of the medical profession have passed over to the great majority. Early in the year Edinburgh had to deplore the death of Dr. ANDREW WOOD, who occupied a high position in the medical world as a physician, a man of letters, and a medical legislator. The Edinburgh University sustained a severe loss in the death of

WILLIAM RUTHERFORD SANDERS, Professor of Pathology. Dr. Sanders was the son of an eminent Edinburgh medical practitioner. He received his early education in France, and in 1849 took the degree of M.D. at the University of Edinburgh, obtaining at the same time the gold medal for his graduation thesis "On the Anatomy of the Spleen." Dr. Sanders was an assiduous contributor to medical literature; he was physician to the infirmary, and Professor of Clinical Medicine, and was in public as in private life held in high-merited esteem and affection by a large circle of patients and friends. In the death of

Dr. PETER HANDYSIDE a well-known and familiar figure was called from Edinburgh circles. Dr. Handyside was likewise by birth an Edinburgh man, and graduated at the University in 1831, where his course as a student was a

distinguished one, in acknowledgement of which he was elected by his fellow-students senior president of their society, the Royal Medical. He was also medallist of the Harveian Society. Early in life he had been an apprentice to Mr. Syme, and this, doubtless, inclined his tastes towards anatomy and surgery. He studied likewise in Paris and Heidelberg, in the latter place under Tiedemann. In 1833 he was admitted a Fellow of the Royal College of Surgeons, and in 1833-34 he commenced his lectures on anatomy at No. 4 Surgeon's Square. At this time Munro Tertius was Professor of Anatomy in the University; and in the extra-mural school the gifted Knox taught anatomy next door to Dr. Handyside. Knox, it is well known, did not spare his rivals; and Dr. Handyside used to relate that he owed his first pupil to the satire of Knox on the presumption of so young a man entering into competition with him. Dr. Handyside's connection with Edinburgh was a long and honourable one, and his memory will be long revered as that of a thoroughly tolerant Christian gentleman. Lasswade lost a respected practitioner in

Dr. WILLIAM MACLAREN, who graduated only in 1866. Subsequent to graduation he studied in Berlin. In August, 1880, dyspeptic symptoms appeared, which were quickly followed by emaciation and pain, and death ensued on the 4th March from cancer of the pylorus, at the early age of 34.

WILLIAM CRICHTON SAUNDERS, L.R.C.S.E., of Dundee, died at Broughty Ferry, where he had resided since failing health incapacitated him for professional duty, on the 25th April. Mr. Saunders was a member of an old Dundee family, where he was born on the 12th April, 1809. On completing his preliminary education he was apprenticed to his grand-uncle, Mr. John Crichton, Dundee, the celebrated lithotomist. He became a licentiate of the Royal College of Surgeons in 1830, and afterwards spent two years in Paris and Montpellier, attending the lectures of Dupuytren and other French celebrities. During the revolution of July, 1830—"the three days"—he was in Paris, and gave assistance to the wounded at the barricades and in hospital. For nearly half a century the deceased enjoyed a large practice in Dundee, and endeared himself to a wide circle by his skill, his kindly sympathy, and unostentatious benevolence. Mr. Saunders was a man of highly cultivated tastes and polished manners, an accurate scholar, and an accomplished linguist. While dying in a distant colony, medical circles in Edinburgh lost a well-known friend in

Dr. FREDERICK W. A. SKAE, third son of the late Dr. Skae, of Morningside. His death occurred at Wellington, New Zealand, on the 25th of June. After graduating at the University of Edinburgh, Dr. Skae studied both in London and Paris. He was assistant-physician to his father at Morningside for some years, after which he received the appointment of medical superintendent of the Stirling Asylum at Larbert, which he resigned on being appointed Medical Inspector of Lunatic Asylums to the colony of New Zealand. He was subsequently made Inspector of Hospitals for the colony. Dr. Skae was of an amiable and genial disposition, possessed a humour and geniality which made him a charming companion. His gentleness of speech and character made him

greatly beloved by his patients. The insane instinctively felt his genuine sympathy. Of a sensitive disposition, it appears, that a succession of worries to which he was subjected in the colony told seriously upon him, depressing his vital energy, and causing his death from an attack of erysipelas. He was an earnest and able public servant, and succumbed prematurely to circumstances, which a coarser and less upright man would have doubtless survived. A melancholy accident, in youth and health, deprived the department of lunacy of

JOSEPH J. BROWN, M.B., F.R.C.P. Edin. Thrown from a gig on the 28th Sept. at Coupar-Fife, he sustained such severe injuries that death took place on the same day. Dr. Brown was the son of a respected medical man at Wooler. He studied at Edinburgh where he took his M.B. degree with credit, and then had the advantage of being a resident in the Royal Infirmary. After this he became an assistant to Dr. Batty Tuke at Saughton Hall Asylum, where he became an enthusiast in nervous pathology. Three years of his subsequent life he spent at Morning-side, and was thence transferred to the Fife Asylum, where he maintained the reputation earned by his predecessors for that institution. He was of a most social disposition, and was highly beloved by a large circle of friends.

In GLASGOW the obstetric department of the profession sustained a loss in the sudden death of

Dr. J. G. WILSON, who occupied the chair of midwifery at Anderson's College. Dr. Wilson was the son of a Glasgow medical man, who likewise devoted special attention to obstetrics. The deceased graduated at the Glasgow University in 1853. He was in the enjoyment of a large practice in the city. A misapplied confidence in occasional assistants made, however, serious inroads on the amount of his work. Of an extremely amiable and active disposition, Dr. Wilson enjoyed a large share of professional esteem, and his loss is regretted by a large circle of friends. On the 21st of June died the immediate predecessor of Dr. Wilson at Anderson's College, Dr. JAMES PATERSON. Dr. Paterson was also the son of a medical man, and entered the profession in 1834. He commenced practice in the east end of the city, where he soon gathered round him a numerous *clientele*; subsequently he migrated to the west end. Dr. Paterson was devoted to his practice, taking but few holidays. As a teacher on midwifery his lectures were much appreciated by the students. In character he was straightforward and manly, commanded the success and respect to which he was so well entitled. Just as we write information has reached this country of the death

of Dr. Paterson's son, Dr. R. H. PATERSON, who also lectured on botany at Anderson's College. Receiving a tempting appointment, he went to Rockhampton, Queensland, where he died in November from the effects of blood-poisoning received in the course of his professional duties. He was aged only 26, and was a well-educated and accomplished gentleman. The premature death of

Dr. DAVID FOULIS, at the age of 35, caused a genuine feeling of sadness in the profession and among the public of Glasgow. He died on the 31st October last from the results, it is believed, of contagion from diphtheria, received when operating in cases of that disease. Dr. Foulis graduated in 1873. After this he spent two years in hospital work at home and on the continent. He was pathologist to the Royal Infirmary of Glasgow, and surgeon to the dispensary of that institution. He was a bold and skilful operator, and was widely known for the success which attended his operations on the throat, a department to which he specially devoted himself. Naturally reticent, he did not appear much in general society, but by those who were privileged to enjoy his friendship and intimacy he was much beloved. In the recent death of

Mr. JOHN REID, a man of excellent character, who will be much missed, has passed away to the unknowable future of which he certainly had no superstitious dread. A native of Glasgow, Mr. Reid studied at the university of that city, and took, in 1833, the licence of the faculty, to which body he always cherished friendly feelings. As our columns so recently contained an obituary notice of him, further recapitulation is unnecessary. Mr. Reid had, doubtless, his angularities; but he possessed other qualities which relegated these to the background; he was truthful; he was manly; he was sympathetic. We have thus been compelled to chronicle a sufficiently long list of fellow-labourers who have entered before us on "the first dark day of nothingness, the last of danger and distress." Men of all periods of life, and of all professional stations, most of whom began the year in robust health, with hopes flattering and prospects bright; and the duty of recalling their memories to our readers, on the threshold of another year, is one not unmixed with solemn thoughts. From our personal knowledge we can testify of some, and of the rest we have the best reason to believe that they were good men and true. Faultlessness we do not claim for them, for they were human. Striving to emulate the behests of their noble calling, we can but hope that having for ever rested from their toil and their petty strifes, they reap—

"In better world the meed
To blameless life by heaven decreed."

METROPOLITAN HOSPITAL SUNDAY FUND.

THE Annual General Meeting of the constituents of the Hospital Sunday Fund took place at the Guildhall on Tuesday last. The Lord Mayor presiding. The report of the Council which we have already referred to was formally received and adopted. A sum of money over and above that authorised to be expended upon surgical appliances was ordered to be paid out of the general fund in the hands of the bankers. It was further resolved, upon the motion of the Rev. Canon Spence, that an alteration be made in the rule constituting the surgical appliance fund, so as to enable the council to expend a further sum of 2 per cent., (taking 4 per cent from future collections) upon surgical appliances. Several speakers warmly supported the change, testifying to the immense amount of good already effected by the existing regulations, and which enabled poor persons, requiring surgical instruments to obtain immediate help, instead of begging from door to door for letters from subscribers to surgical aid societies. Cardinal Manning pointed to the list of 1,023 appliances distributed to the poor during the past year as proving the importance of such a provision, and the necessity for a further increase, it being within his own knowledge that many poor persons would but for the timely aid afforded by the fund, have been driven into the workhouse. We would add one remark with regard to the larger expenditure proposed: That it seems to require a good deal of care and additional discrimination to see that nothing like imposition is practised upon the Council fund. It is manifestly impossible to eliminate self-interest from human affairs, and the way in which the Hospital Sunday Fund is disposed of concerns the public at large no less than the executive. It would be much to the advantage of the fund, if a proper business arrangement were made for the purchase of instruments by contract or from one wholesale house of repute, which we believe has not yet been acted upon. A check should likewise be placed upon the indiscriminate distribution of expensive forms of surgical appliances, and their bestowal upon unworthy objects of charity. The whole of this wants watching indeed with a good deal of care, we might say with more care than has hitherto been bestowed.

The 11th of June, next year, was fixed upon for Hospital Sunday.

THE annual rates of mortality last week in the large towns of the United Kingdom per 1,000 of their population were—Bristol 15, Plymouth 16, Edinburgh 16, Norwich 19, Portsmouth 19, Newcastle-on-Tyne 19, Bradford 20, Sunderland 20, Leeds 21, London 22, Leicester 23, Sheffield 23, Glasgow 23, Nottingham 23, Brighton 24, Oldham 24, Wolverhampton 24, Birmingham 27, Salford 29, Hull 30, Liverpool 32, Dublin 33, and Manchester 34.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 37, Bombay 24, Madras 34, Paris 27, Geneva 20, Brussels 21, Amsterdam 22, Rotterdam 29, The Hague 21,

Copenhagen 24, Stockholm 16, Christiana 16, St. Petersburg 38, Berlin 23, Hamburg 23, Dresden 18, Breslau 28, Munich 26, Vienna 24, Prague 31, Buda-Pesth 30, Naples 25, Turin 19, Venice 22, Alexandria 30, New York 29, Brooklyn 20, Philadelphia 19, and Baltimore 22. No returns were received from Rome or Lisbon.

FROM diseases of the zymotic class last week in the large towns, the highest death-rate per 1,000 were:—From scarlet fever, 8·7 in Hull, 3·9 in Nottingham, and 3·1 in Sunderland; from measles, 2·5 in Liverpool, and 2·8 in Plymouth; from whooping-cough, 2·1 both in Leicester and Salford; and from "fever" (principally enteric), 1·2 in Portsmouth, and 1·0 both in Brighton and Leeds. In Hull 26 more fatal cases of scarlet fever were recorded, raising the number registered within this borough since the beginning of July to 587. The 33 deaths from diphtheria included 12 in London, 8 in Glasgow, 5 in Portsmouth, and 3 in Birmingham. Small-pox caused 25 more deaths in London and 1 in Hull, whereas no fatal case was registered in any of the other large towns.

NEW YEAR'S GIFT-BOOKS FOR THE YOUNG.

WE have before us the bound volumes for the present year of "The Boy's Own Paper" and "The Girl's Own Paper," and we can conceive nothing that boys or girls under about fifteen years of age would be more delighted with than these annuals. There is so much pernicious literature published, presumably for the edification of the young, but actually for their destruction, that it is a pleasure—in fact, it becomes the duty of conductors of the press—to commend to the attention of parents such works as those before us. During their progress in monthly parts through the year we have scanned many a well-told tale—many an instructive article with pleasure; and the children to whom we gave them have testified their appreciation with unbounded delight. Throughout these volumes a high moral tone pervades, without any admixture of the goody-goody nonsense, or uncharitable sneer at this or that religious sect. "The Boy's Own Annual," and "The Girl's Own Annual," are works that can be placed with safety in the hands of the young; and even those not in their 'teens will find in them much to entertain and amuse.

South London School of Pharmacy.—At this popular School, the prizes were presented to the following successful competitors in the lecture room of the Institution, on Dec. 17th, 1881:—Senior Chemistry Medal: E. John Bull. Certificate: Herbert Shaw. Junior Chemistry Medal: W. I. Mignot Tucker. Certificate: Walter Lloyd. Botany Medal: Clement Caldicot. Certificate: Frederick E. Tozer. Materia Medica Medal: H. Hardy White. Certificate: W. I. M. Tucker. Practical Pharmacy and Dispensary Medal: Frederick E. Tozer. Certificate: C. Caldicot.

NOTICES TO CORRESPONDENTS.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

THE INDEX.—The Index for the present volume will be given in our next number.

TO OUR READERS.—With the first number of the new volume for 1882 we propose continuing those valuable Lectures commenced during this month—"On Symptoms," by Frederick T. Roberts, M.D., B.Sc., F.R.C.P., Professor of Materia Medica and Therapeutics at University College, Physician and Professor of Clinical Medicine at University College Hospital; and the Harvelan Lectures "On Menstruation and its Derangements," by Alfred Meadows, M.D., F.R.C.P., &c., Physician to, and Lecturer on Midwifery and Diseases of Women and Children at, St. Mary's Hospital. We have also many promises of Lectures, Original Communications, and Clinical Records from the leading hospital physicians and surgeons throughout the United Kingdom, exceeding any previous year.

We would also remind those of our readers who are not attached to hospitals that our columns are equally open to them for correspondence and for "Cases in Private Practice;" these form the most useful feature, because the most practical of a medical journal, as by such records, and the comparison of notes and experience of others, many valuable lessons and useful hints are derived for the more perfect understanding and practice of our art. Whilst thanking those gentlemen who have in this manner contributed to our common stock of knowledge during the year now closing, we would wish to impress the utility of this department upon all our readers, and hope they will assist therein in increasing numbers during the coming year. We beg, also, to thank our subscribers for their continued and increasing support; some have kindly introduced new subscribers to our ranks, and during the year nearly 200 additional names have been added to our List, whilst scarcely any, except by death, have ceased their support. The new year, therefore, dawns upon us very brightly, a prospect, we sincerely hope, that awaits all our readers.

TO CANDIDATES FOR THE ARMY MEDICAL SERVICE.—Notice is given in our advertising columns of the next examination for appointments in the Medical Department of Her Majesty's Army. The date fixed is February 20th, and following days, but applications must be made in due form at least fourteen days prior to this.

MR. WATSON (Manchester) is referred to a little work, "Notes on Drugs," published by Messrs. Corbyn, Stacey, & Co, of London. Thymol, he will see, is a crystalline substance obtained from Oil of Thyme, slightly soluble in water, very soluble in alcohol, with a highly aromatic odour. In strong solution it acts as a caustic, and is also a powerful antiseptic. Comparative experiments with salicylic and carbolic acids show that thymol possesses much greater power than either of these acids in arresting fermentation in a solution of sugar containing yeast. When inhaled it is a strong stimulant and disinfectant, and has been recommended in pharyngitis and laryngitis when associated with exanthemata; for this purpose the Throat Hospital Pharmacopoeia gives the following formula: Thymol, 20 grains; rectified spirit, 3 drams; light carbonate of magnesia, 10 grains; water to 3 oz. A teaspoonful in 20 oz. of water at 150° F. for each inhalation.

STUDENTS will find the information he seeks in our "Student's Number," Sept. 21st. The following number, also, contains advice on the choice of books which he will do well to study before deciding.

THE JACKSONIAN PRIZE.—Intending competitors are reminded that their essays must be sent in not later than Saturday next.

ETIQUETTE.—Such conduct is unbecoming a gentleman; as he appears to be in unconscious possession of education, we would suggest that you should instruct him in its development by the opposite course of conduct, when good manners, which should spring therefrom, will follow as a matter of course.

STUCK.—The difficulty is a real one, especially as you confess to a bad memory. We have a book on our table for review, "Schematic Anatomy," by Dr. Mears, of the University of Durham Medical School, on a new basis, which would probably assist to impress the parts upon your memory.

A CANDIDATE.—The alteration in the bye-laws took place a short time since; candidates for the diploma of membership will henceforth be examined in midwifery unless holding a recognised licence showing that they have been examined in that branch of medicine.

ONE ANXIOUS FOR REFORM.—The whole question has been gone into by the Parliamentary Commission, and we shall probably hear of suggestions being made in the direction indicated in your letter when the report is presented. We were from the first in favour of conjoint examinations, and have never ceased to advocate this change as a

means of counteracting the disreputable practices of certain colleges. This much needed reform must come eventually.

MR. F. G. L.—The local paper containing report of case to which you allude has not yet been received.

MR. WELLS (Blackburn).—We do not prescribe in these columns. Consult a local practitioner of known ability.

BARTLE.—Appropriate to the season, but hardly so to our columns.

DR. RIDLEY DALE (Sunderland).—Came too late for insertion this week.

THE QUACKS OF THE OLD TIMES.—As a contrast with the advertisements of the present hour in our newspapers, we reproduce a couple of specimens from the original edition of Addison's *Spectator*, published in the reign of Queen Anne. The first relates to the cure of "stuttering and stammering," &c., and the second to the "loss of memory." Listen to the quack: "An admirable confection which assuredly cures stuttering and stammering in children or grown persons, though never so bad, causing them to speak distinct and free without any trouble or difficulty; it remedies all manner of impediments in the speech or disorders of the voice of any kind proceeding from what cause soever, rendering those persons capable of speaking easily and free, and with a clear voice, who before were not able to utter a sentence without hesitation. Its stupendous effects in so quickly and infallibly curing stuttering and stammering and all disorders of the voice and difficulty in delivery of the speech are really wonderful. Price 2s. 6d. a pot, with directions. Sold only at Mr. Osborn's Toy Shop at the Rose and Crown, under St. Dunstan's Church, Fleet Street." Here is the second nostrum:—"Loss of memory, or forgetfulness, certainly cured by a grateful electuary peculiarly adapted for that end; it strikes at the primary source, which few apprehend, of forgetfulness, makes the head clear and easy, the spirits free, active, and undisturbed; corroborates and revives all the noble faculties of the soul, such as thought, judgment, apprehension, reason, and memory, which last in particular it so strengthens as to render that faculty exceeding quick and good beyond imagination; thereby enabling those whose memory was before almost totally lost to remember the minutest circumstance of their affairs, &c., to a wonder. Price 2s. 6d. a pot. Sold only at Mr. Payne's, at the Angel and Crown in St. Paul's Churchyard, with directions."

Vacancies.

Birmingham.—Resident Second Assistant Medical Officer to the Workhouse. Salary, £150. Applications to "The Guardians of the Poor," Paradise Street, to be sent in on or before Jan. 4.

Gravesend Dispensary and Infirmary.—House Surgeon and Dispenser. Salary, £100, with board. Applications to the Hon. Sec. before Jan. 10.
